  AS SELECT * FROM employees;
```

As a benchmark, list those salaries less than 2500:

```
SELECT salary
  FROM employees_test
 WHERE salary < 2500;
```

| SALARY |
|--------|
| 2400   |
| 2200   |
| 2100   |
| 2400   |
| 2200   |

#### Note:

To allow time for the SCN to propagate to the mapping table used by the `FLASHBACK TABLE` statement, wait a minimum of 5 minutes prior to issuing the following statement. This wait would not be necessary if a previously existing table were being used in this example.

Enable row movement for the table:

```
ALTER TABLE employees_test
  ENABLE ROW MOVEMENT;
```

Issue a 10% salary increase to those employees earning less than 2500:

```
UPDATE employees_test
  SET salary = salary * 1.1
 WHERE salary < 2500;
```

```
5 rows updated.
COMMIT;
```

As a second benchmark, list those salaries that remain less than 2500 following the 10% increase:

```
SELECT salary
  FROM employees_test
 WHERE salary < 2500;
```

```
-----  
SALARY  
-----  
2420  
2310  
2420
```

Restore the table `employees_test` to its state prior to the current system time. The unrealistic duration of 1 minute is used so that you can test this series of examples quickly. Under normal circumstances a much greater interval would have elapsed.

```
FLASHBACK TABLE employees_test
  TO TIMESTAMP (SYSTIMESTAMP - INTERVAL '1' minute);
```

List those salaries less than 2500. After the `FLASHBACK TABLE` statement issued above, this list should match the list in the first benchmark.

```
SELECT salary
  FROM employees_test
 WHERE salary < 2500;
```

```
-----  
SALARY  
-----  
2400  
2200  
2100  
2400  
2200
```

### Retrieving a Dropped Table: Example

If you accidentally drop the `pm.print_media` table and want to retrieve it, then issue the following statement:

```
FLASHBACK TABLE print_media TO BEFORE DROP;
```

If another `print_media` table has been created in the `pm` schema, then use the `RENAME TO` clause to rename the retrieved table:

```
FLASHBACK TABLE print_media TO BEFORE DROP RENAME TO print_media_old;
```

If you know that the `employees` table has been dropped multiple times, and you want to retrieve the oldest version, then query the `USER_RECYCLEBIN` table to determine the system-generated name, and then use that name in the `FLASHBACK TABLE` statement. (System-generated names in your database will differ from those shown here.)

```
SELECT object_name, droptime FROM user_recyclebin
 WHERE original_name = 'PRINT_MEDIA';
```

| OBJECT_NAME           | DROPTIME            |
|-----------------------|---------------------|
| RB\$\$45703\$TABLE\$0 | 2003-06-03:15:26:39 |
| RB\$\$45704\$TABLE\$0 | 2003-06-12:12:27:27 |
| RB\$\$45705\$TABLE\$0 | 2003-07-08:09:28:01 |

# GRANT

## Purpose

Use the GRANT statement to grant:

- System privileges to users and roles. [Table 18-1](#) lists the system privileges (organized by the database object operated upon).  
  
Note that ANY system privileges, for example, SELECT ANY TABLE, will not work on SYS objects or other dictionary objects.
- Schema privileges to users and roles. [Table 18-3](#) lists the schema privileges organized by the operations authorized.
- Roles to users, roles, and program units. The granted roles can be either user-defined (local or external) or predefined. For a list of predefined roles, refer to *Oracle Database Security Guide*.
- Object privileges for a particular object to users and roles. [Table 18-2](#) lists the object privileges (organized by the database object operated upon).

 **Note:**

Global roles (created with IDENTIFIED GLOBALLY) are granted through enterprise roles and cannot be granted using the GRANT statement.

## Notes on Authorizing Database Users

You can authorize database users through means other than the database and the GRANT statement.

- Many Oracle Database privileges are granted through supplied PL/SQL and Java packages. For information on those privileges, refer to the documentation for the appropriate package.
- Some operating systems have facilities that let you grant roles to Oracle Database users with the initialization parameter OS\_ROLES. If you choose to grant roles to users through operating system facilities, then you cannot also grant roles to users with the GRANT statement, although you can use the GRANT statement to grant system privileges to users and system privileges and roles to other roles.

## Note on Oracle Automatic Storage Management

A user authenticated AS SYSASM can use this statement to grant the system privileges SYSASM, SYSOPER, and SYSDBA to a user in the Oracle ASM password file of the current node.

## Note on Editable Objects

A GRANT operation to grant object privileges on an editable object actualizes the object in the current edition. See *Oracle Database Development Guide* for more information about editions and editable objects.

 See Also:

- [CREATE USER](#) and [CREATE ROLE](#) for definitions of local, global, and external privileges
- *Oracle Database Security Guide* for information about other authorization methods and for information about privileges
- [REVOKE](#) for information on revoking grants

### Prerequisites

To grant a **system privilege**, one of the following conditions must be met:

- You must have been granted the `GRANT ANY PRIVILEGE` system privilege. In this case, if you grant the system privilege to a role, then a user to whom the role has been granted does not have the privilege unless the role is enabled in user's session.
- You must have been granted the system privilege with the `ADMIN OPTION`. In this case, if you grant the system privilege to a role, then a user to whom the role has been granted has the privilege regardless whether the role is enabled in the user's session.

To grant a **role to a user or another role**, you must have been directly granted the role with the `ADMIN OPTION`, or you must have been granted the `GRANT ANY ROLE` system privilege, or you must have created the role.

To grant a **role to a program unit in your own schema**, you must have been directly granted the role with either the `ADMIN OPTION` or the `DELEGATE OPTION`, or you must have been granted the `GRANT ANY ROLE` system privilege, or you must have created the role.

To grant a **role to a program unit in another user's schema**, you must be the user `SYS` and the role must have been created by the schema owner or directly granted to the schema owner.

To grant an **object privilege on a user**, by specifying the `ON USER` clause of the `on_object_clause`, you must be the user on whom the privilege is granted, or you must have been granted the object privilege on that user with the `WITH GRANT OPTION`, or you must have been granted the `GRANT ANY OBJECT PRIVILEGE` system privilege. If you can grant an object privilege on a user only because you have the `GRANT ANY OBJECT PRIVILEGE`, then the `GRANTOR` column of the `*_TAB_PRIVS` views displays the user on whom the privilege is granted rather than the user who issued the `GRANT` statement.

To grant an **object privilege on all other types of objects**, you must own the object, or the owner of the object must have granted you the object privileges with the `WITH GRANT OPTION`, or you must have been granted the `GRANT ANY OBJECT PRIVILEGE` system privilege. If you have the `GRANT ANY OBJECT PRIVILEGE`, then you can grant the object privilege only if the object owner could have granted the same object privilege. In this case, the `GRANTOR` column of the `*_TAB_PRIVS` views displays the object owner rather than the user who issued the `GRANT` statement.

You can revoke privileges on an object if you have the `GRANT ANY` object privilege. This does not apply to `SYS` objects. The `ANY` keyword in reference to a system privilege means that the user can perform the privilege on any objects owned by any user except for `SYS`.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root.

### Syntax

*grant ::=*

(*grant\_system\_privileges ::=, grant\_schema\_privileges ::=, grant\_object\_privileges ::=, grant\_roles\_to\_programs ::=*)

*grant\_system\_privileges ::=*

(*grantee\_clause ::=, grantee\_identified\_by ::=*)

*grant\_schema\_privileges ::=*

*grantee\_clause ::=*

*grantee\_identified\_by::=*

*grant\_object\_privileges ::=*

(*on\_object\_clause ::=*, *grantee\_clause ::=*)

*on\_object\_clause ::=*

*grant\_roles\_to\_programs ::=*

### *program\_unit ::=*

## Semantics

### ***grant\_system\_privileges***

Use these clauses to grant system privileges.

## ***system\_privilege***

Specify the system privilege you want to grant. [Table 18-1](#) lists the system privileges, organized by the database object operated upon.

- If you grant a privilege to a **user**, then the database adds the privilege to the user's privilege domain. The user can immediately exercise the privilege. Oracle recommends that you only grant the **ANY** privileges to trusted users.
  - If you grant a privilege to a **role**, then the database adds the privilege to the privilege domain of the role. Users who have been granted and have enabled the role can immediately exercise the privilege. Other users who have been granted the role can enable the role and exercise the privilege.

## See Also:

[Granting a System Privilege to a User: Example](#) and ["Granting System Privileges to a Role: Example"](#)

- If you grant a privilege to **PUBLIC**, then the database adds the privilege to the privilege domains of each user. All users can immediately perform operations authorized by the privilege. Oracle recommends against granting system privileges to **PUBLIC**.

*role*

Specify the role you want to grant. You can grant an Oracle Database predefined role or a user-defined role.

- If you grant a role to a **user**, then the database makes the role available to the user. The user can immediately enable the role and exercise the privileges in the privilege domain of the role.

In the case of a secure application role, you need not grant such a role directly to the user. You can let the associated PL/SQL package do this, assuming the user passes appropriate security policies. For more information, see the CREATE ROLE semantics for [USING package](#) and *Oracle Database Security Guide*.

- If you grant a role to another **role**, then the database adds the privilege domain of the granted role to the privilege domain of the grantee role. Users who have been granted the grantee role can enable it and exercise the privileges in the granted role's privilege domain.
- If you grant a role to **PUBLIC**, then the database makes the role available to all users. All users can immediately enable the role and exercise the privileges in the privilege domain of the role.

## ALL PRIVILEGES

Specify **ALL PRIVILEGES** to grant all of the system privileges listed in [Table 18-1](#), except the **SELECT ANY DICTIONARY**, **ALTER DATABASE LINK**, and **ALTER PUBLIC DATABASE LINK** privileges.

However, grant and revoke **ALL PRIVILEGES** do not apply to **ADMINISTER KEY MANAGEMENT**. Granting **ALL PRIVILEGES** does not grant **ADMINISTER KEY MANAGEMENT**. Similarly, revoking **ALL PRIVILEGES** does not revoke **ADMINISTER KEY MANAGEMENT**.

### See Also:

- [Oracle Database Security Guide](#) for information on the Oracle predefined roles
- ["Granting a Role to a Role: Example"](#)
- [CREATE ROLE](#) for information on creating a user-defined role

## **grantee\_clause**

Use the **grantee\_clause** to specify the users or roles to which the system privilege, role, or object privilege is granted.

## **PUBLIC**

Specify **PUBLIC** to grant the privileges to all users. Oracle recommends against granting system privileges to **PUBLIC**.

## **Restriction on Grantees**

A user, role, or **PUBLIC** cannot appear more than once in the **grantee\_clause**.

## **grantee\_identified\_by**

The **grantee\_identified\_by** clause lets you assign passwords to users when granting them system privileges and roles. You must specify an equal number of users and passwords. The first password is assigned to the first user, the second password is assigned to the second user, and so on. If a specified user exists, then the database resets the user's password. If a specified user does not exist, then the database creates the user with the password.

You can set the password to a maximum length of 1024 bytes.

### See Also:

- [CREATE USER](#) for restrictions on usernames and passwords and ["Assigning User Passwords When Granting a System Privilege: Example"](#)

## WITH ADMIN OPTION

Specify WITH ADMIN OPTION to enable the grantee to:

- Grant the privilege or role to another user or role, unless the role is a GLOBAL role
- Revoke the privilege or role from another user or role
- Alter the privilege or role to change the authorization needed to access it
- Drop the privilege or role
- Grant the role to a program unit in the grantee's schema.
- Revoke the role from a program unit in the grantee's schema.

If you grant a system privilege or role to a user without specifying WITH ADMIN OPTION, and then subsequently grant the privilege or role to the user WITH ADMIN OPTION, then the user has the ADMIN OPTION on the privilege or role.

To revoke the ADMIN OPTION on a system privilege or role from a user, you must revoke the privilege or role from the user altogether and then grant the privilege or role to the user without the ADMIN OPTION.

 **See Also:**

["Granting a Role with the ADMIN OPTION: Example"](#)

## WITH DELEGATE OPTION

You can specify this clause only when granting a role to a user.

Specify WITH DELEGATE OPTION to enable the grantee to:

- Grant the role to a program unit in the grantee's schema
- Revoke the role from a program unit in the grantee's schema

If you grant a role to a user without specifying WITH DELEGATE OPTION, and then subsequently grant the role to the user WITH DELEGATE OPTION, then the user has the DELEGATE OPTION on the role.

To revoke the DELEGATE OPTION on a role from a user, you must revoke the role from the user altogether and then grant the role to the user without the DELEGATE OPTION.

 **See Also:**

- ["Granting a Role with the DELEGATE OPTION: Example"](#)
- The [`grant\_roles\_to\_programs`](#) clause for more information on granting roles to program units

## Restrictions on Granting System Privileges and Roles

Privileges and roles are subject to the following restrictions:

- A privilege or role cannot appear more than once in the list of privileges and roles to be granted.
- You cannot grant a role to itself.
- You cannot grant a role IDENTIFIED GLOBALLY to anything.
- You cannot grant a role IDENTIFIED EXTERNALLY to a global user or global role.
- You cannot grant roles circularly. For example, if you grant the role `banker` to the role `teller`, then you cannot subsequently grant `teller` to `banker`.
- You cannot grant an IDENTIFIED BY role, IDENTIFIED USING role, or IDENTIFIED EXTERNALLY role to another role.

### ***grant\_schema\_privileges***

You can grant a schema level privilege to any user or any role if you are a user who :

- Owns the schema.
- Has a schema level privilege WITH ADMIN OPTION.
- Has the GRANT ANY SCHEMA PRIVILEGE system privilege. If you specify ALL PRIVILEGES , all the schema level privileges in [Table 18-3](#) are granted.

You cannot grant schema privileges on the `SYS` schema.

#### **See Also:**

*Schema Privileges to Simplify Access Control in the Oracle Database Security Guide*

### ***grant\_object\_privileges***

Use these clauses to grant object privileges.

#### ***object\_privilege***

Specify the object privilege you want to grant. [Table 18-2](#) lists the object privileges, organized by the type of object on which they can be granted. When you grant an object privilege on a editionable object, either to a user or to a role, the object is actualized in the edition in which the grant is made. Refer to [CREATE EDITION](#) for information on editionable object types and editions.

 **Note:**

To grant `SELECT` on a view to another user, either you must own all of the objects underlying the view or you must have been granted the `SELECT` object privilege `WITH GRANT OPTION` on all of those underlying objects. This is true even if the grantee already has `SELECT` privileges on those underlying objects.

To grant `READ` on a view to another user, either you must own all of the objects underlying the view or you must have been granted the `READ` or `SELECT` object privilege `WITH GRANT OPTION` on all of those underlying objects. This is true even if the grantee already has the `READ` or `SELECT` privilege on those underlying objects.

### Restriction on Object Privileges

A privilege cannot appear more than once in the list of privileges to be granted.

#### **ALL [PRIVILEGES]**

Specify `ALL` to grant all the privileges for the object that you have been granted with the `GRANT OPTION`. The user who owns the schema containing an object automatically has all privileges on the object with the `GRANT OPTION`. The keyword `PRIVILEGES` is provided for semantic clarity and is optional.

#### ***column***

Specify the table or view column on which privileges are to be granted. You can specify columns only when granting the `INSERT`, `REFERENCES`, or `UPDATE` privilege. If you do not list columns, then the grantee has the specified privilege on all columns in the table or view.

For information on existing column object grants, query the `USER_`, `ALL_`, or `DBA_COL_PRIVS` data dictionary view.

 **See Also:**

*Oracle Database Reference* for information on the data dictionary views and "[Granting Multiple Object Privileges on Individual Columns: Example](#)"

#### ***on\_object\_clause***

The `on_object_clause` identifies the object on which the privileges are granted. Users, directory objects, editions, data mining models, Java source and resource schema objects, and SQL translation profiles are identified separately because they reside in separate namespaces.

 **See Also:**

["Granting Object Privileges to a Role: Example"](#)

### **object**

Specify the schema object on which the privileges are to be granted. If you do not qualify *object* with *schema*, then the database assumes the object is in your own schema. The object can be one of the following types:

- Table, view, or materialized view
- Sequence
- Procedure, function, or package
- User-defined type
- Synonym for any of the preceding items
- Directory, library, operator, or indextype
- Java source, class, or resource

You cannot grant privileges directly to a single partition of a partitioned table.

 **See Also:**

["Granting Object Privileges on a Table to a User: Example"](#), ["Granting Object Privileges on a View: Example"](#), and ["Granting Object Privileges to a Sequence in Another Schema: Example"](#)

### **ON USER**

Specify the database user you want to grant privileges to.

#### **Restriction on Granting Privileges on Users**

You cannot grant privileges on user PUBLIC.

 **See Also:**

["Granting an Object Privilege on a User: Example"](#)

### **ON DIRECTORY**

Specify the name of the directory object on which privileges are to be granted. You cannot qualify *directory\_name* with a schema name.

 **See Also:**

[CREATE DIRECTORY](#) and "Granting an Object Privilege on a Directory: Example"

#### ON EDITION

Specify the name of the edition on which the `USE` object privilege is to be granted. You cannot qualify `edition_name` with a schema name.

#### ON MINING MODEL

Specify the name of the mining model on which privileges are to be granted. If you do not qualify `mining_model_name` with `schema`, then the database assumes that the mining model is in your own schema.

#### ON JAVA SOURCE | RESOURCE

Specify the name of the Java source or resource schema object on which privileges are to be granted. If you do not qualify `object` with `schema`, then the database assumes that the object is in your own schema.

 **See Also:**

[CREATE JAVA](#)

#### ON SQL TRANSLATION PROFILE

Specify the name of the SQL translation profile on which privileges are to be granted. If you do not qualify `profile` with `schema`, then the database assumes that the profile is in your own schema.

#### WITH HIERARCHY OPTION

Specify `WITH HIERARCHY OPTION` to grant the specified object privilege on all subobjects of `object`, such as subviews created under a view, including subobjects created subsequent to this statement.

This clause is meaningful only in combination with the `READ` or `SELECT` object privilege.

#### WITH GRANT OPTION

Specify `WITH GRANT OPTION` to enable the grantee to grant the object privileges to other users and roles.

If you grant an object privilege to a user without specifying `WITH GRANT OPTION`, and then subsequently grant the privilege to the user `WITH GRANT OPTION`, then the user has the `GRANT OPTION` on the privilege.

To revoke the `GRANT OPTION` on an object privilege from a user, you must revoke the privilege from the user altogether and then grant the privilege to the user without the `GRANT OPTION`.

#### Restriction on Granting WITH GRANT OPTION

You can specify WITH GRANT OPTION only when granting to a user or to PUBLIC, not when granting to a role.

#### ***grant\_roles\_to\_programs***

Use this clause to grant roles to program units. Such roles are called code based access control (CBAC) roles.

#### ***role***

Specify the role you want to grant. You can grant an Oracle Database predefined role or a user-defined role. The role must have been created by or directly granted to the schema owner of the program unit.

#### ***program\_unit***

Specify the program unit to which the role is to be granted. You can specify a PL/SQL function, procedure, or package. If you do not specify *schema*, then Oracle Database assumes the function, procedure, or package is in your own schema.

#### **See Also:**

*Oracle Database Security Guide* for more information on granting code based access control roles to program units

### **CONTAINER Clause**

If the current container is a pluggable database (PDB):

- Specify CONTAINER = CURRENT to locally grant a system privilege, object privilege, or role to a user or role. The privilege or role is granted to the user or role only in the current PDB.

If the current container is the root:

- Specify CONTAINER = CURRENT to locally grant a system privilege, object privilege, or role to a common user or common role. The privilege or role is granted to the user or role only in the root.
- Specify CONTAINER = ALL to commonly grant a system privilege, object privilege on a common object, or role, to a common user or common role.

If you omit this clause, then CONTAINER = CURRENT is the default.

#### **Note:**

If you specify the CONTAINER clause when granting a privilege or role, then the current container must be the same container and you must specify the same CONTAINER clause when you revoke the privilege or role. Refer to the [CONTAINER Clause](#) of the REVOKE statement for more information.

**Listings of System, Object, and Schema Privileges****Table 18-1 System Privileges (Organized by the Database Object Operated Upon)**

| <b>System Privilege Name</b>         | <b>Operations Authorized</b>                                                                                                                                                                                                                                             |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Advisor Framework Privileges:</b> | All of the advisor framework privileges are part of the DBA role.                                                                                                                                                                                                        |
| ADVISOR                              | Access the advisor framework through PL/SQL packages such as <code>DBMS_ADVISOR</code> and <code>DBMS_SQLTUNE</code> .                                                                                                                                                   |
| ADMINISTER SQL TUNING SET            | Create, drop, select (read), load (write), and delete SQL tuning sets owned by the grantee through the <code>DBMS_SQLTUNE</code> package.                                                                                                                                |
| ADMINISTER ANY SQL TUNING SET        | Create, drop, select (read), load (write), and delete SQL tuning sets owned by any user through the <code>DBMS_SQLTUNE</code> package.                                                                                                                                   |
| CREATE ANY SQL PROFILE               | Accept a SQL Profile recommended by the SQL Tuning Advisor, which is accessed through Enterprise Manager or by the <code>DBMS_SQLTUNE</code> package.<br><br><b>Note:</b> This privilege has been deprecated in favor of <code>ADMINISTER SQL MANAGEMENT OBJECT</code> . |
| ALTER ANY SQL PROFILE                | Alter the attributes of an existing SQL Profile.<br><br><b>Note:</b> This privilege has been deprecated in favor of <code>ADMINISTER SQL MANAGEMENT OBJECT</code> .                                                                                                      |
| DROP ANY SQL PROFILE                 | Drop existing SQL Profiles.<br><br><b>Note:</b> This privilege has been deprecated in favor of <code>ADMINISTER SQL MANAGEMENT OBJECT</code> .                                                                                                                           |
| ADMINISTER SQL MANAGEMENT OBJECT     | Create, alter, and drop SQL Profiles owned by any user through the <code>DBMS_SQLTUNE</code> package.                                                                                                                                                                    |
| <b>ANALYTIC VIEWS</b>                | —                                                                                                                                                                                                                                                                        |
| CREATE ANALYTIC VIEW                 | Create analytic views in the grantee's schema.                                                                                                                                                                                                                           |

| CREATE INDEXTYPE                | Create indextypes in the grantee's schema.                                                                                                                                                                                                                                                                |
| CREATE ANY INDEXTYPE            | Create indextypes in any schema except SYS and create comments on indextypes in any schema except SYS.                                                                                                                                                                                                    |
| ALTER ANY INDEXTYPE             | Modify indextypes in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                       |
| DROP ANY INDEXTYPE              | Drop indextypes in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                         |
| EXECUTE ANY INDEXTYPE           | Reference indextypes in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                    |
| <b>JOB SCHEDULER OBJECTS:</b>   | The following privileges are needed to execute procedures in the DBMS_SCHEDULER package. This privilege does not apply to lightweight jobs, which are not database objects. Refer to <i>Oracle Database Administrator's Guide</i> for more information about lightweight jobs.                            |
| CREATE JOB                      | Create, alter, or drop jobs, chains, schedules, programs, credentials, resource objects, or incompatibility resource objects in the grantee's schema.                                                                                                                                                     |
| CREATE ANY JOB                  | Create, alter, or drop jobs, chains, schedules, programs, credentials, resource objects, or incompatibility resource objects in any schema except SYS, AUDSYS.<br><b>Note:</b> This extremely powerful privilege allows the grantee to execute code as any other user. It should be granted with caution. |
| CREATE EXTERNAL JOB             | Create in the grantee's schema an executable scheduler job that runs on the operating system.                                                                                                                                                                                                             |
| EXECUTE ANY CLASS               | Specify any job class in a job in the grantee's schema.                                                                                                                                                                                                                                                   |
| EXECUTE ANY PROGRAM             | Use any program in a job in the grantee's schema.                                                                                                                                                                                                                                                         |

**Table 18-1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)**

| <b>System Privilege Name</b>     | <b>Operations Authorized</b>                                                                                                                                                                                                                                    |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MANAGE SCHEDULER                 | Create, alter, or drop any job class, window, or window group.                                                                                                                                                                                                  |
| USE ANY JOB RESOURCE             | Associate any schedule resource object with any program or job in the grantee's schema.                                                                                                                                                                         |
| <b>KEY MANAGEMENT FRAMEWORK:</b> | —                                                                                                                                                                                                                                                               |
| ADMINISTER KEY MANAGEMENT        | Manage keys and keystores.                                                                                                                                                                                                                                      |
| <b>LIBRARIES:</b>                | <b>Caution:</b> CREATE LIBRARY, CREATE ANY LIBRARY, ALTER ANY LIBRARY, and EXECUTE ANY LIBRARY are extremely powerful privileges that should be granted only to trusted users. Refer to <i>Oracle Database Security Guide</i> before granting these privileges. |
| CREATE LIBRARY                   | Create external procedure or function libraries in the grantee's schema.                                                                                                                                                                                        |
| CREATE ANY LIBRARY               | Create external procedure or function libraries in any schema except SYS, AUDSYS.                                                                                                                                                                               |
| ALTER ANY LIBRARY                | Alter external procedure or function libraries in any schema except SYS, AUDSYS.                                                                                                                                                                                |
| DROP ANY LIBRARY                 | Drop external procedure or function libraries in any schema except SYS, AUDSYS.                                                                                                                                                                                 |
| EXECUTE ANY LIBRARY              | Use external procedure or function libraries in any schema except SYS, AUDSYS.                                                                                                                                                                                  |
| <b>LOGMINER:</b>                 | —                                                                                                                                                                                                                                                               |
| LOGMINING                        | Execute procedures in the DBMS_LOGMNR package in a CDB or a PDB. Query the contents of the V\$LOGMNR_CONTENTS view.                                                                                                                                             |
| <b>MATERIALIZED VIEWS:</b>       | —                                                                                                                                                                                                                                                               |
| CREATE MATERIALIZED VIEW         | Create materialized views in the grantee's schema.                                                                                                                                                                                                              |
| CREATE ANY MATERIALIZED VIEW     | Create materialized views in any schema except SYS, AUDSYS.                                                                                                                                                                                                     |
| ALTER ANY MATERIALIZED VIEW      | Alter materialized views in any schema except SYS, AUDSYS.                                                                                                                                                                                                      |
| DROP ANY MATERIALIZED VIEW       | Drop materialized views in any schema except SYS, AUDSYS.                                                                                                                                                                                                       |
| QUERY REWRITE                    | This privilege has been deprecated. No privileges are needed for a user to enable rewrite for a materialized view that references tables or views in the user's own schema.                                                                                     |
| GLOBAL QUERY REWRITE             | Enable rewrite using a materialized view when that materialized view references tables or views in any schema except SYS.                                                                                                                                       |
| ON COMMIT REFRESH                | Create a refresh-on-commit materialized view on any table in the database.<br>Alter a refresh-on-demand materialized view on any table in the database to refresh-on-commit.                                                                                    |
| FLASHBACK ANY TABLE              | Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.                                                                                           |
| <b>MINING MODELS:</b>            | —                                                                                                                                                                                                                                                               |
| CREATE MINING MODEL              | Create mining models in the grantee's schema using the DBMS_DATA_MINING.CREATE_MODEL procedure.                                                                                                                                                                 |

**Table 18-1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)**

| System Privilege Name             | Operations Authorized                                                                                                                                                                                                                                              |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CREATE ANY MINING MODEL           | Create mining models in any schema, except SYS, AUDSYS, using the DBMS_DATA_MINING.CREATE_MODEL procedure.                                                                                                                                                         |
| ALTER ANY MINING MODEL            | Change the mining model name or the associated cost matrix of a model in any schema, except SYS, AUDSYS, using the applicable DBMS_DATA_MINING procedures.                                                                                                         |
| DROP ANY MINING MODEL             | Drop mining models in any schema, except SYS, AUDSYS, using the DBMS_DATA_MINING.DROP_MODEL procedure.                                                                                                                                                             |
| SELECT ANY MINING MODEL           | Score or view mining models in any schema except SYS, AUDSYS. Scoring is done either with the PREDICTION family of SQL functions or with the DBMS_DATA_MINING.APPLY procedure. Viewing the model is done with the DBMS_DATA_MINING.GET_MODEL_DETAILS_* procedures. |
| COMMENT ANY MINING MODEL          | Create comments on mining models in any schema, except SYS, AUDSYS, using the SQL COMMENT statement.                                                                                                                                                               |
| <b>OLAP CUBES:</b>                | The following privileges are valid when you are using Oracle Database with the OLAP option.                                                                                                                                                                        |
| CREATE CUBE                       | Create OLAP cubes in the grantee's schema.                                                                                                                                                                                                                         |
| CREATE ANY CUBE                   | Create OLAP cubes in any schema except SYS, AUDSYS.                                                                                                                                                                                                                |
| ALTER ANY CUBE                    | Alter OLAP cubes in any schema except SYS, AUDSYS.                                                                                                                                                                                                                 |
| DROP ANY CUBE                     | Drop OLAP cubes in any schema except SYS, AUDSYS.                                                                                                                                                                                                                  |
| SELECT ANY CUBE                   | Query or view OLAP cubes in any schema except SYS, AUDSYS.                                                                                                                                                                                                         |
| UPDATE ANY CUBE                   | Update OLAP cubes in any schema except SYS, AUDSYS.                                                                                                                                                                                                                |
| <b>OLAP CUBE MEASURE FOLDERS:</b> | The following privileges are valid when you are using Oracle Database with the OLAP option.                                                                                                                                                                        |
| CREATE MEASURE FOLDER             | Create OLAP measure folders in the grantee's schema.                                                                                                                                                                                                               |
| CREATE ANY MEASURE FOLDER         | Create OLAP measure folders in any schema except SYS, AUDSYS.                                                                                                                                                                                                      |
| DELETE ANY MEASURE FOLDER         | Delete a measure from an OLAP measure folder in any schema except SYS, AUDSYS.                                                                                                                                                                                     |

**Table 18-1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)**

| <b>System Privilege Name</b>      | <b>Operations Authorized</b>                                                                                                                               |
|-----------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INSERT ANY CUBE DIMENSION         | Insert into OLAP cube dimensions in any schema except SYS, AUDSYS.                                                                                         |
| SELECT ANY CUBE DIMENSION         | View or query OLAP cube dimensions in any schema except SYS, AUDSYS.                                                                                       |
| UPDATE ANY CUBE DIMENSION         | Update OLAP cube dimensions in any schema except SYS, AUDSYS.                                                                                              |
| <b>OLAP CUBE BUILD PROCESSES:</b> | —                                                                                                                                                          |
| CREATE CUBE BUILD PROCESS         | Create OLAP cube build processes in the grantee's schema.                                                                                                  |
| CREATE ANY CUBE BUILD PROCESS     | Create OLAP cube build processes in any schema except SYS, AUDSYS.                                                                                         |
| DROP ANY CUBE BUILD PROCESS       | Drop OLAP cube build processes in any schema except SYS, AUDSYS.                                                                                           |
| UPDATE ANY CUBE BUILD PROCESS     | Update OLAP cube build processes in any schema except SYS, AUDSYS.                                                                                         |
| <b>OPERATORS:</b>                 | —                                                                                                                                                          |
| CREATE OPERATOR                   | Create an operator and its bindings in the grantee's schema.                                                                                               |
| CREATE ANY OPERATOR               | Create an operator and its bindings in any schema and create a comment on an operator in any schema.                                                       |
| ALTER ANY OPERATOR                | Modify operators in any schema.                                                                                                                            |
| DROP ANY OPERATOR                 | Drop operators in any schema.                                                                                                                              |
| EXECUTE ANY OPERATOR              | Reference operators in any schema.                                                                                                                         |
| <b>OUTLINES:</b>                  | —                                                                                                                                                          |
| CREATE ANY OUTLINE                | Create public outlines that can be used in any schema that uses outlines.                                                                                  |
| ALTER ANY OUTLINE                 | Modify outlines.                                                                                                                                           |
| DROP ANY OUTLINE                  | Drop outlines.                                                                                                                                             |
| <b>PDB LOCKDOWN PROFILES:</b>     | —                                                                                                                                                          |
| CREATE LOCKDOWN PROFILE           | Create PDB lockdown profiles.                                                                                                                              |
| ALTER LOCKDOWN PROFILE            | Alter PDB lockdown profiles.                                                                                                                               |
| DROP LOCKDOWN PROFILE             | Drop PDB lockdown profiles.                                                                                                                                |
| <b>PLAN MANAGEMENT:</b>           | —                                                                                                                                                          |
| ADMINISTER SQL MANAGEMENT OBJECT  | Perform controlled manipulation of plan history and SQL plan baselines maintained for various SQL statements.                                              |
| <b>PLUGGABLE DATABASES:</b>       | —                                                                                                                                                          |
| CREATE PLUGGABLE DATABASE         | Create a PDB.<br>Plug in a PDB that was previously unplugged from a CDB.<br>Clone a PDB.                                                                   |
| SET CONTAINER                     | Allow a common user to switch into the container for which this privilege was granted. This privilege can be granted only to a common user or common role. |

**Table 18-1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)**

| <b>System Privilege Name</b>  | <b>Operations Authorized</b>                                                                                                            |
|-------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>PROCEDURES:</b>            | —                                                                                                                                       |
| CREATE PROCEDURE              | Create stored procedures, functions, or packages in the grantee's schema.                                                               |
| CREATE ANY PROCEDURE          | Create stored procedures, functions, or packages in any schema except SYS, AUDSYS.                                                      |
| ALTER ANY PROCEDURE           | Alter stored procedures, functions, or packages in any schema except SYS, AUDSYS.                                                       |
| DROP ANY PROCEDURE            | Drop stored procedures, functions, or packages in any schema except SYS, AUDSYS.                                                        |
| EXECUTE ANY PROCEDURE         | Execute procedures or functions, either standalone or packaged.<br>Reference public package variables in any schema except SYS, AUDSYS. |
| INHERIT ANY REMOTE PRIVILEGES | Execute definer's rights procedures or functions that contain current user database links.                                              |
| <b>PROFILES:</b>              | —                                                                                                                                       |
| CREATE PROFILE                | Create profiles.                                                                                                                        |
| ALTER PROFILE                 | Alter profiles.                                                                                                                         |
| DROP PROFILE                  | Drop profiles.                                                                                                                          |
| <b>PROPERTY GRAPHS:</b>       | —                                                                                                                                       |
| CREATE PROPERTY GRAPH         | Create property graph in the grantee's schema.                                                                                          |
| CREATE ANY PROPERTY GRAPH     | Create property graph in any schema except SYS, AUDSYS.                                                                                 |
| ALTER ANY PROPERTY GRAPH      | Alter property graph in any schema except SYS, AUDSYS.                                                                                  |
| DROP ANY PROPERTY GRAPH       | Drop property graph in any schema except SYS, AUDSYS.                                                                                   |
| READ ANY PROPERTY GRAPH       | Query property graph in any schema except SYS, AUDSYS.                                                                                  |
| <b>ROLES:</b>                 | —                                                                                                                                       |
| CREATE ROLE                   | Create roles.                                                                                                                           |
| ALTER ANY ROLE                | Alter any role in the database.                                                                                                         |
| DROP ANY ROLE                 | Drop roles.                                                                                                                             |
| GRANT ANY ROLE                | Grant any role in the database.                                                                                                         |
| <b>ROLLBACK SEGMENTS:</b>     | —                                                                                                                                       |
| CREATE ROLLBACK SEGMENT       | Create rollback segments.                                                                                                               |
| ALTER ROLLBACK SEGMENT        | Alter rollback segments.                                                                                                                |
| DROP ROLLBACK SEGMENT         | Drop rollback segments.                                                                                                                 |
| <b>SEQUENCES:</b>             | —                                                                                                                                       |
| CREATE SEQUENCE               | Create sequences in the grantee's schema.                                                                                               |
| CREATE ANY SEQUENCE           | Create sequences in any schema except SYS, AUDSYS.                                                                                      |
| ALTER ANY SEQUENCE            | Alter sequences in any schema except SYS, AUDSYS.                                                                                       |
| DROP ANY SEQUENCE             | Drop sequences in any schema except SYS, AUDSYS.                                                                                        |

**Table 18-1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)**

| <b>System Privilege Name</b>       | <b>Operations Authorized</b>                                                                                                                                                                                                                                     |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SELECT ANY SEQUENCE                | Reference sequences in any schema except SYS, AUDSYS.                                                                                                                                                                                                            |
| <b>SESSIONS:</b>                   | —                                                                                                                                                                                                                                                                |
| CREATE SESSION                     | Connect to the database.                                                                                                                                                                                                                                         |
| ALTER RESOURCE COST                | Set costs for session resources.                                                                                                                                                                                                                                 |
| ALTER SESSION                      | Enable and disable the SQL trace facility.                                                                                                                                                                                                                       |
| RESTRICTED SESSION                 | Logon after the instance is started using the SQL*Plus STARTUP RESTRICT statement.                                                                                                                                                                               |
| <b>SNAPSHOTS:</b>                  | See MATERIALIZED VIEWS                                                                                                                                                                                                                                           |
| <b>SQL Firewall Administration</b> | —                                                                                                                                                                                                                                                                |
| ADMINISTER SQL FIREWALL            | This system privilege is required to execute the PL/SQL procedures in SYS.DBMS_SQL_FIREWALL package. Just like any other system privileges, SYS is assumed to have this privilege. However this system privilege will not be granted to the DBA role by default. |
| <b>SQL TRANSLATION PROFILES:</b>   | —                                                                                                                                                                                                                                                                |
| CREATE SQL TRANSLATION PROFILE     | Create SQL translation profiles in the grantee's schema.                                                                                                                                                                                                         |
| CREATE ANY SQL TRANSLATION PROFILE | Create SQL translation profiles in any schema except SYS, AUDSYS.                                                                                                                                                                                                |
| ALTER ANY SQL TRANSLATION PROFILE  | Alter the translator, custom SQL statement translations, or custom error translations of a SQL translation profile in any schema except SYS, AUDSYS.                                                                                                             |
| USE ANY SQL TRANSLATION PROFILE    | Use SQL translation profiles in any schema except SYS, AUDSYS.                                                                                                                                                                                                   |
| DROP ANY SQL TRANSLATION PROFILE   | Drop SQL translation profiles in any schema except SYS, AUDSYS.                                                                                                                                                                                                  |
| TRANSLATE ANY SQL                  | Translate SQL through the grantee's SQL translation profile for any user.                                                                                                                                                                                        |
| <b>SYNONYMS:</b>                   | <b>Caution:</b> CREATE PUBLIC SYNONYM and DROP PUBLIC SYNONYM are extremely powerful privileges that should be granted only to trusted users. Refer to <i>Oracle Database Security Guide</i> before granting these privileges.                                   |
| CREATE SYNONYM                     | Create synonyms in the grantee's schema.                                                                                                                                                                                                                         |
| CREATE ANY SYNONYM                 | Create private synonyms in any schema except SYS, AUDSYS.                                                                                                                                                                                                        |
| CREATE PUBLIC SYNONYM              | Create public synonyms.                                                                                                                                                                                                                                          |
| DROP ANY SYNONYM                   | Drop private synonyms in any schema except SYS, AUDSYS.                                                                                                                                                                                                          |
| DROP PUBLIC SYNONYM                | Drop public synonyms.                                                                                                                                                                                                                                            |
| <b>TABLES:</b>                     | <b>Note:</b> For external tables, the only valid privileges are CREATE ANY TABLE, ALTER ANY TABLE, DROP ANY TABLE, READ ANY TABLE, and SELECT ANY TABLE.                                                                                                         |
| CREATE TABLE                       | Create tables in the grantee's schema.                                                                                                                                                                                                                           |
| CREATE ANY TABLE                   | Create a table in any schema except SYS, AUDSYS. The owner of the schema containing the table must have space quota on the tablespace to contain the table.                                                                                                      |

**Table 18-1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)**

| <b>System Privilege Name</b> | <b>Operations Authorized</b>                                                                                                                                                                                                                                                                                                                  |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ALTER ANY TABLE              | Alter a table or view in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                                       |
| BACKUP ANY TABLE             | Use the Export utility to incrementally export objects from the schema of other users except SYS, AUDSYS.                                                                                                                                                                                                                                     |
| DELETE ANY TABLE             | Delete rows from tables, table partitions, or views in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                         |
| DROP ANY TABLE               | Drop or truncate tables or table partitions in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                 |
| INSERT ANY TABLE             | Insert rows into tables and views in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                           |
| LOCK ANY TABLE               | Lock tables and views in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                                       |
| READ ANY TABLE               | Query tables, views, or materialized views in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                  |
| SELECT ANY TABLE             | Query tables, views, or materialized views in any schema except SYS, AUDSYS. Obtain row locks using a SELECT ... FOR UPDATE.                                                                                                                                                                                                                  |
| FLASHBACK ANY TABLE          | Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS, AUDSYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.                                                                                                                                                                 |
| UPDATE ANY TABLE             | Update rows in tables and views in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                             |
| REDEFINE ANY TABLE           | Perform online redefinition without granting any of the privileges in USER or FULL mode.                                                                                                                                                                                                                                                      |
| TABLE RETENTION              | Create a blockchain table or an immutable table whose table retention exceeds the threshold specified by the parameter BLOCKCHAIN_TABLE_RETENTION_THRESHOLD. Increase the table retention for an existing blockchain table or immutable table to a value above the threshold specified by the parameter BLOCKCHAIN_TABLE_RETENTION_THRESHOLD. |
| <b>TABLESPACES:</b>          | —                                                                                                                                                                                                                                                                                                                                             |
| CREATE TABLESPACE            | Create tablespaces.                                                                                                                                                                                                                                                                                                                           |
| ALTER TABLESPACE             | Alter tablespaces.                                                                                                                                                                                                                                                                                                                            |
| DROP TABLESPACE              | Drop tablespaces.                                                                                                                                                                                                                                                                                                                             |
| MANAGE TABLESPACE            | Take tablespaces offline and online and begin and end tablespace backups.                                                                                                                                                                                                                                                                     |
| UNLIMITED TABLESPACE         | Use an unlimited amount of any tablespace. This privilege overrides any specific quotas assigned. If you revoke this privilege from a user, then the user's schema objects remain but further tablespace allocation is denied unless authorized by specific tablespace quotas. You cannot grant this system privilege to roles.               |
| <b>TRIGGERS:</b>             | —                                                                                                                                                                                                                                                                                                                                             |
| CREATE TRIGGER               | Create database triggers in the grantee's schema.                                                                                                                                                                                                                                                                                             |
| CREATE ANY TRIGGER           | Create database triggers in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                                    |
| ALTER ANY TRIGGER            | Enable, disable, or compile database triggers in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                               |

**Table 18-1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)**

| <b>System Privilege Name</b> | <b>Operations Authorized</b>                                                                                                                                                                                                                                                                                                                             |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DROP ANY TRIGGER             | Drop database triggers in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                                                 |
| ADMINISTER DATABASE TRIGGER  | Create a trigger on DATABASE. You must also have the CREATE TRIGGER or CREATE ANY TRIGGER system privilege.                                                                                                                                                                                                                                              |
| <b>TYPES:</b>                | —                                                                                                                                                                                                                                                                                                                                                        |
| CREATE TYPE                  | Create object types and object type bodies in the grantee's schema.                                                                                                                                                                                                                                                                                      |
| CREATE ANY TYPE              | Create object types and object type bodies in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                             |
| ALTER ANY TYPE               | Alter object types in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                                                     |
| DROP ANY TYPE                | Drop object types and object type bodies in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                               |
| EXECUTE ANY TYPE             | Use and reference object types and collection types in any schema except SYS, AUDSYS, and invoke methods of an object type in any schema, except SYS, AUDSYS, if you make the grant to a specific user. If you grant EXECUTE ANY TYPE to a role, then users holding the enabled role will not be able to invoke methods of an object type in any schema. |
| UNDER ANY TYPE               | Create subtypes under any nonfinal object types.                                                                                                                                                                                                                                                                                                         |
| <b>USERS:</b>                | —                                                                                                                                                                                                                                                                                                                                                        |
| CREATE USER                  | Create users. This privilege also allows the creator to: <ul style="list-style-type: none"> <li>• Assign quotas on any tablespace.</li> <li>• Set default and temporary tablespaces.</li> <li>• Assign a profile as part of a CREATE USER statement.</li> </ul>                                                                                          |
| ALTER USER                   | Alter any user except SYS. This privilege authorizes the grantee to: <ul style="list-style-type: none"> <li>• Change another user's password or authentication method.</li> <li>• Assign quotas on any tablespace.</li> <li>• Set default and temporary tablespaces.</li> <li>• Assign a profile and default roles.</li> </ul>                           |
| DROP USER                    | Drop users                                                                                                                                                                                                                                                                                                                                               |
| <b>VIEWS:</b>                | —                                                                                                                                                                                                                                                                                                                                                        |
| CREATE VIEW                  | Create views in the grantee's schema.                                                                                                                                                                                                                                                                                                                    |
| CREATE ANY VIEW              | Create views in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                                                           |
| DROP ANY VIEW                | Drop views in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                                                             |
| UNDER ANY VIEW               | Create subviews under any object views.                                                                                                                                                                                                                                                                                                                  |
| FLASHBACK ANY TABLE          | Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS, AUDSYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.                                                                                                                                                                            |

**Table 18-1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)**

| System Privilege Name | Operations Authorized                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MERGE ANY VIEW        | If a user has been granted the MERGE ANY VIEW privilege, then for any query issued by that user, the optimizer can use view merging to improve query performance without performing the checks that would otherwise be performed to ensure that view merging does not violate any security intentions of the view creator. See also <i>Oracle Database Reference</i> for information on the OPTIMIZER_SECURE_VIEW_MERGING parameter and <i>Oracle Database SQL Tuning Guide</i> for information on view merging.                                                                                                              |
| <b>MISCELLANEOUS:</b> | —                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ANALYZE ANY           | Analyze a table, cluster, or index in any schema except SYS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| AUDIT ANY             | Audit an object in any schema, except SYS, AUDSYS, using AUDIT schema_objects statements.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| BECOME USER           | <p>Allow users of the Data Pump Import utility (impdp) and the original Import utility (imp) to assume the identity of another user in order to perform operations that cannot be directly performed by a third party (for example, loading objects such as object privilege grants).</p> <p>Allow Streams administrators to create or alter capture users and apply users in a Streams environment. By default this privilege is part of the DBA role. Database Vault removes this privilege from the DBA role. Therefore, this privilege is needed by Streams only in an environment where Database Vault is installed.</p> |
| CHANGE NOTIFICATION   | Create a registration on queries and receive database change notifications in response to DML or DDL changes to the objects associated with the registered queries. Refer to <i>Oracle Database Development Guide</i> for more information on database change notification.                                                                                                                                                                                                                                                                                                                                                   |
| COMMENT ANY TABLE     | Comment on a table, view, or column in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ENABLE DIAGNOSTICS    | <ul style="list-style-type: none"> <li>• Set debug-events via ALTER SESSION or ALTER SYSTEM</li> <li>• Set debug-actions to execute during an event via ALTER SESSION or ALTER SYSTEM</li> <li>• Execute debug-actions immediately via ALTER SESSION or ALTER SYSTEM by specifying the IMMEDIATE keyword instead of an event name</li> <li>• Set the event parameter in the spfile via ALTER SYSTEM</li> </ul>                                                                                                                                                                                                                |
| EXEMPT ACCESS POLICY  | <p>Bypass fine-grained access control.</p> <p><b>Caution:</b> This is a very powerful system privilege, as it lets the grantee bypass application-driven security policies. Database administrators should use caution when granting this privilege.</p>                                                                                                                                                                                                                                                                                                                                                                      |
| FORCE ANY TRANSACTION | <p>Force the commit or rollback of any in-doubt distributed transaction in the local database.</p> <p>Induce the failure of a distributed transaction.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| FORCE TRANSACTION     | Force the commit or rollback of the grantee's in-doubt distributed transactions in the local database.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 18-1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)**

| <b>System Privilege Name</b> | <b>Operations Authorized</b>                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GRANT ANY OBJECT PRIVILEGE   | Grant any object privilege that the object owner is permitted to grant.<br><br>Revoke any object privilege that was granted by the object owner or by some other user with the GRANT ANY OBJECT PRIVILEGE privilege.                                                                                                                                                                                                                                             |
| GRANT ANY PRIVILEGE          | Grant any system privilege.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| INHERIT ANY PRIVILEGES       | Execute invoker's rights procedures owned by the grantee with the privileges of the invoker.                                                                                                                                                                                                                                                                                                                                                                     |
| KEEP DATE TIME               | The SYSDATE and SYSTIMESTAMP functions return their original values during replay for Application Continuity when the grantee is running the application. This privilege is useful for providing bind variable consistency after recoverable errors.<br><br><b>Note:</b> If this privilege is granted or revoked between runtime and failover of a request, then the original values are not returned during replay for Application Continuity for that request. |
| KEEP SYSGUID                 | The SYS_GUID function returns its original value during replay for Application Continuity when the grantee is running the application. This privilege is useful for providing bind variable consistency after recoverable errors.<br><br><b>Note:</b> If this privilege is granted or revoked between runtime and failover of a request, then the original value is not returned during replay for Application Continuity for that request.                      |
| PURGE DBA_RECYCLEDBIN        | Remove all objects from the system-wide recycle bin.                                                                                                                                                                                                                                                                                                                                                                                                             |
| RESUMABLE                    | Enable resumable space allocation.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| SELECT ANY DICTIONARY        | Query any data dictionary object in the SYS schema, with the exception of the following objects: DEFAULT_PWD\$, ENC\$, LINK\$, USER\$, USER_HISTORY\$, and XS\$VERIFIERS.                                                                                                                                                                                                                                                                                        |
| SELECT ANY TRANSACTION       | Query the contents of the FLASHBACK_TRANSACTION_QUERY view.<br><br><b>Caution:</b> This is a very powerful system privilege, as it lets the grantee view all data in the database, including past data. This privilege should be granted only to users who need to use the Oracle Flashback Transaction Query feature.                                                                                                                                           |

**Table 18-1 (Cont.) System Privileges (Organized by the Database Object Operated Upon)**

| System Privilege Name | Operations Authorized                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>ANALYTIC VIEW PRIVILEGES</b>         | The following <b>analytic view privileges</b> authorize operations on analytic views.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| ALTER                                   | Rename the analytic view.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| READ                                    | Query the object with the SELECT statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| SELECT                                  | Query the object with the SELECT statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>ATTRIBUTE DIMENSION PRIVILEGES</b>   | The following <b>attribute dimension privileges</b> authorize operations on attribute dimensions..                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ALTER                                   | Rename the attribute dimension.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DIRECTORY PRIVILEGES</b>             | The following <b>directory privileges</b> provide secured access to the files stored in the operating system directory to which the directory object serves as a pointer. The directory object contains the full path name of the operating system directory where the files reside. Because the files are actually stored outside the database, Oracle Database server processes also need to have appropriate file permissions on the file system server. Granting object privileges on the directory database object to individual database users, rather than on the operating system, allows the database to enforce security during file operations. |
| READ                                    | Read files in the directory.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| WRITE                                   | Write files in the directory. This privilege is useful only in connection with external tables. It allows the grantee to determine whether the external table agent can write a log file or a bad file to the directory.<br><b>Restriction:</b> This privilege does not allow the grantee to write to a BFILE.                                                                                                                                                                                                                                                                                                                                             |
| EXECUTE                                 | Execute a preprocessor program that resides in the directory. A preprocessor program converts data to a supported format when loading data records from an external table with the ORACLE_LOADER access driver. Refer to <i>Oracle Database Utilities</i> for more information. This privilege does not implicitly allow READ access on the external table data.                                                                                                                                                                                                                                                                                           |
| <b>EDITION PRIVILEGE</b>                | The following <b>edition privilege</b> authorizes the use of an edition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| USE                                     | Use an edition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>FLASHBACK DATA ARCHIVE PRIVILEGE</b> | The following <b>flashback data archive privilege</b> authorizes operations on flashback data archives.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| FLASHBACK ARCHIVE                       | Enable or disable historical tracking for a table.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>HIERARCHY PRIVILEGES</b>             | The following <b>hierarchy privileges</b> authorize operations on hierarchies.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ALTER                                   | Rename the hierarchy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| READ                                    | Query the object with the SELECT statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| SELECT                                  | Query the object with the SELECT statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>INDEXTYPE PRIVILEGE</b>              | The following <b>indextype privilege</b> authorizes operations on indextypes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| EXECUTE                                 | Reference an indextype.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>LIBRARY PRIVILEGE</b>                | The following <b>library privilege</b> authorizes operations on a library.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| EXECUTE                                 | Use and reference the specified object and invoke its methods.<br><b>Caution:</b> This extremely powerful privilege should be granted only to trusted users. Refer to <i>Oracle Database Security Guide</i> before granting this privilege.                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 18-2 (Cont.) Object Privileges (Organized by the Database Object Operated Upon)**

| Object Privilege Name               | Operations Authorized                                                                                                                                                                                                         |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MATERIALIZED VIEW PRIVILEGES</b> | The following <b>materialized view privileges</b> authorize operations on a materialized view. The DELETE, INSERT, and UPDATE privileges can be granted only to updatable materialized views.                                 |
| ON COMMIT REFRESH                   | Create a refresh-on-commit materialized view on the specified table.                                                                                                                                                          |
| QUERY REWRITE                       | Create a materialized view for query rewrite using the specified table.                                                                                                                                                       |
| READ                                | Query the materialized view.                                                                                                                                                                                                  |
| SELECT                              | Query the materialized view. Obtain row locks with the SELECT ... FOR UPDATE or LOCK TABLE statement.                                                                                                                         |
| <b>MINING MODEL PRIVILEGES</b>      | The following mining model privileges authorize operations on a mining model. These privileges are not required for models within the users own schema.                                                                       |
| ALTER                               | Change the mining model name or the associated cost matrix using the applicable DBMS_DATA_MINING procedures.                                                                                                                  |
| SELECT                              | Score or view the mining model. Scoring is done with the PREDICTION family of SQL functions or with the DBMS_DATA_MINING.APPLY procedure. Viewing the model is done with the DBMS_DATA_MINING.GET_MODEL_DETAILS_* procedures. |
| <b>OBJECT TYPE PRIVILEGES</b>       | The following <b>object type privileges</b> authorize operations on a database object type.                                                                                                                                   |
| DEBUG                               | Access, through a debugger, all public and nonpublic variables, methods, and types defined on the object type.<br>Place a breakpoint or stop at a line or instruction boundary within the type body.                          |
| EXECUTE                             | Use and reference the specified object and invoke its methods.<br>Access, through a debugger, public variables, types, and methods defined on the object type.                                                                |
| UNDER                               | Create a subtype under this type. You can grant this object privilege only if you have the UNDER ANY TYPE privilege WITH GRANT OPTION on the immediate supertype of this type.                                                |
| <b>OLAP PRIVILEGES</b>              | The following object privileges are valid if you are using Oracle Database with the OLAP option.                                                                                                                              |
| INSERT                              | Insert members into the OLAP cube dimension or measures into the measures folder.                                                                                                                                             |
| ALTER                               | Change the definition of the OLAP cube dimension or cube.                                                                                                                                                                     |
| DELETE                              | Delete members from the OLAP cube dimension or measures from the measures folder.                                                                                                                                             |
| SELECT                              | View or query the OLAP cube or cube dimension.                                                                                                                                                                                |
| UPDATE                              | Update measure values of the OLAP cube or attribute values of the cube dimension.                                                                                                                                             |
| <b>OPERATOR PRIVILEGE</b>           | The following <b>operator privilege</b> authorizes operations on user-defined operators.                                                                                                                                      |
| EXECUTE                             | Reference an operator.                                                                                                                                                                                                        |

**Table 18-2 (Cont.) Object Privileges (Organized by the Database Object Operated Upon)**

| Object Privilege Name                              | Operations Authorized                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PROCEDURE, FUNCTION,<br/>PACKAGE PRIVILEGES</b> | The following <b>procedure, function, and package privileges</b> authorize operations on procedures, functions, and packages. These privileges also apply to <b>Java sources, classes, and resources</b> , which Oracle Database treats as though they were procedures for purposes of granting object privileges.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| DEBUG                                              | <p>Access, through a debugger, all public and nonpublic variables, methods, and types defined on the object.</p> <p>Place a breakpoint or stop at a line or instruction boundary within the procedure, function, or package. This privilege grants access to the declarations in the method or package specification and body.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| EXECUTE                                            | <p>Execute the procedure or function directly, or access any program object declared in the specification of a package, or compile the object implicitly during a call to a currently invalid or uncompiled function or procedure. This privilege does not allow the grantee to explicitly compile using <code>ALTER PROCEDURE</code> or <code>ALTER FUNCTION</code>. For explicit compilation you need the appropriate <code>ALTER</code> system privilege.</p> <p>Access, through a debugger, public variables, types, and methods defined on the procedure, function, or package. This privilege grants access to the declarations in the method or package specification only.</p> <p>Job scheduler objects are created using the <code>DBMS_SCHEDULER</code> package. After these objects are created, you can grant the <code>EXECUTE</code> object privilege on job scheduler classes and programs. You can also grant <code>ALTER</code> privilege on job scheduler jobs, programs, and schedules.</p> <p><b>Note:</b> Users do not need this privilege to execute a procedure, function, or package indirectly.</p> |
| <b>PROPERTY GRAPH<br/>PRIVILEGES</b>               | The following object privileges authorize operations on property graphs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| ALTER                                              | Change the graph definition using <code>ALTER PROPERTY GRAPH</code> statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table 18-2 (Cont.) Object Privileges (Organized by the Database Object Operated Upon)**

| Object Privilege Name                     | Operations Authorized                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| KEEP SEQUENCE                             | <p>The sequence pseudocolumn NEXTVAL retains its original value during replay for Application Continuity when the grantee is running the application. This privilege is useful for providing bind variable consistency when replaying after recoverable errors.</p> <p>If this privilege is granted or revoked between runtime and failover of a request, then the original value of NEXTVAL is not retained during replay for Application Continuity for that request.</p> <p><b>Note:</b> This privilege is not granted by the GRANT ALL PRIVILEGES ON <i>sequence</i> statement. You must explicitly grant this privilege.</p> <p><b>Note:</b> This privilege is part of the DBA role.</p> |
| SELECT                                    | Examine and increment values of the sequence with the CURRVAL and NEXTVAL pseudocolumns.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SQL TRANSLATION PROFILE PRIVILEGES</b> | The following <b>SQL translation profile privileges</b> authorize operations on a SQL translation profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| ALTER                                     | Alter the translator, custom SQL statement translations, or custom error translations of a SQL translation profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| USE                                       | Use a SQL translation profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNONYM PRIVILEGES</b>                 | <p><b>Synonym privileges</b> are the same as the privileges for the target object. Granting a privilege on a synonym is equivalent to granting the privilege on the base object. Similarly, granting a privilege on a base object is equivalent to granting the privilege on all synonyms for the object. If you grant a user a privilege on a synonym, then the user can use either the synonym name or the base object name in the SQL statement that exercises the privilege.</p>                                                                                                                                                                                                          |
| <b>TABLE PRIVILEGES</b>                   | <p>The following <b>table privileges</b> authorize operations on a table. Any one of following object privileges, except the READ privilege, allows the grantee to lock the table in any lock mode with the LOCK TABLE statement.</p> <p><b>Note:</b> For external tables, the only valid object privileges are ALTER, READ, and SELECT.</p>                                                                                                                                                                                                                                                                                                                                                  |
| ALTER                                     | Change the table definition with the ALTER TABLE statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| DEBUG                                     | <p>Access, through a debugger:</p> <ul style="list-style-type: none"> <li>• PL/SQL code in the body of any triggers defined on the table</li> <li>• Information on SQL statements that reference the table directly</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| DELETE                                    | <p>Remove rows from the table with the DELETE statement.</p> <p><b>Note:</b> You must grant the SELECT privilege on the table along with the DELETE privilege if the table is on a remote database.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| INDEX                                     | Create an index on the table with the CREATE INDEX statement.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| INSERT                                    | <p>Add new rows to the table with the INSERT statement.</p> <p><b>Note:</b> You must grant the SELECT privilege on the table along with the INSERT privilege if the table is on a remote database.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| READ                                      | Query the table with the SELECT statement. Does not allow SELECT ... FOR UPDATE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| REFERENCES                                | Create a constraint that refers to the table. You cannot grant this privilege to a role.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table 18-2 (Cont.) Object Privileges (Organized by the Database Object Operated Upon)**

| Object Privilege Name     | Operations Authorized                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SELECT                    | To allow access to specific tables during queries, grant the <code>SELECT</code> privilege on the table.<br><br>Query the table with the <code>SELECT</code> statement, including <code>SELECT ... FOR UPDATE</code> .                                                                                                                                                                                                                                                             |
| UPDATE                    | Change data in the table with the <code>UPDATE</code> statement.<br><br><b>Note:</b> You must grant the <code>SELECT</code> privilege on the table along with the <code>UPDATE</code> privilege if the table is on a remote database.                                                                                                                                                                                                                                              |
| FLASHBACK                 | To allow access to a specific table during queries, grant the <code>FLASHBACK</code> privilege on the table.<br><br>Issue a SQL Flashback Query on the table.                                                                                                                                                                                                                                                                                                                      |
| SIGN                      | A user SCOTT with the <code>SIGN</code> privilege on a blockchain table can sign a row in the blockchain table as a delegate if the following conditions are met:<br><br>The row does not already have a delegate signature<br>The row does not contain a non-NULL delegate user ID that is different than the ID of user SCOTT.                                                                                                                                                   |
| <b>USER PRIVILEGES</b>    | The following privileges authorize operations on a user.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| INHERIT PRIVILEGES        | Execute invoker's rights procedures or functions owned by the grantee with the privileges of the invoker when the invoker is the user on whom this privilege is granted.                                                                                                                                                                                                                                                                                                           |
| INHERIT REMOTE PRIVILEGES | Allow the user on whom this privilege is granted to execute definer's rights procedures or functions that contain current user database links and are owned by the grantee.                                                                                                                                                                                                                                                                                                        |
| TRANSLATE SQL             | Translate SQL through the grantee's SQL translation profile for the user on whom this privilege is granted.                                                                                                                                                                                                                                                                                                                                                                        |
| <b>VIEW PRIVILEGES</b>    | The following <b>view privileges</b> authorize operations on a view. Any one of the following object privileges, except the <code>READ</code> privilege, allows the grantee to lock the view in any lock mode with the <code>LOCK TABLE</code> statement.<br><br>To grant a privilege on a view, you must have that privilege with the <code>GRANT OPTION</code> on all of the base tables of the view.                                                                            |
| DEBUG                     | Access, through a debugger: <ul style="list-style-type: none"><li>• PL/SQL code in the body of any triggers defined on the view</li><li>• Information on SQL statements that reference the view directly</li></ul>                                                                                                                                                                                                                                                                 |
| DELETE                    | Remove rows from the view with the <code>DELETE</code> statement.                                                                                                                                                                                                                                                                                                                                                                                                                  |
| INSERT                    | Add new rows to the view with the <code>INSERT</code> statement.                                                                                                                                                                                                                                                                                                                                                                                                                   |
| MERGE VIEW                | This object privilege has the same behavior as the system privilege <code>MERGE ANY VIEW</code> , except that the privilege is limited to the views specified in the <code>ON</code> clause. For any query issued by the grantee on the specified views, the optimizer can use view merging to improve query performance without performing the checks that would otherwise be performed to ensure that view merging does not violate any security intentions of the view creator. |
| READ                      | Query the view with the <code>SELECT</code> statement. Does not allow <code>SELECT ... FOR UPDATE</code> .                                                                                                                                                                                                                                                                                                                                                                         |
| REFERENCES                | Define foreign key constraints on the view.                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 18-2 (Cont.) Object Privileges (Organized by the Database Object Operated Upon)**

| Object Privilege Name | Operations Authorized                                                                                                                                                                                  |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SELECT                | Query the view with the SELECT statement, including SELECT ... FOR UPDATE.<br><b>See Also:</b> <a href="#">object_privilege</a> for additional information on granting this object privilege on a view |
| UNDER                 | Create a subview under this view. You can grant this object privilege only if you have the UNDER ANY VIEW privilege WITH GRANT OPTION on the immediate superview of this view.                         |
| UPDATE                | Change data in the view with the UPDATE statement.                                                                                                                                                     |
| FLASHBACK             | To allow access to a specific view during queries, grant the FLASHBACK privilege on the view.<br>Issue a SQL Flashback Query on the view.                                                              |

**Table 18-3 Schema Privileges (Organized by the Operations Authorized)**

| Schema Privilege Name          | Operations Authorized                                                                                                                                                                           |
|--------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>ANALYTIC VIEWS</b>          | —                                                                                                                                                                                               |
| CREATE ANY ANALYTIC VIEW       | Create analytic views in any schema except SYS, AUDSYS.<br>If the grantee is the schema owner, then grantee should have been granted CREATE ANALYTIC VIEW privilege.                            |
| ALTER ANY ANALYTIC VIEW        | Rename analytic views in any schema except SYS, AUDSYS.                                                                                                                                         |
| DROP ANY ANALYTIC VIEW         | Drop analytic views in any schema except SYS, AUDSYS .                                                                                                                                          |
| <b>ATTRIBUTE DIMENSIONS</b>    | —                                                                                                                                                                                               |
| CREATE ANY ATTRIBUTE DIMENSION | Create attribute dimensions in any schema except SYS, AUDSYS.<br>If the grantee is the schema owner, then grantee should have been granted CREATE ATTRIBUTE DIMENSION privilege.                |
| ALTER ANY ATTRIBUTE DIMENSION  | Rename attribute dimensions in any schema except SYS, AUDSYS.                                                                                                                                   |
| DROP ANY ATTRIBUTE DIMENSION   | Drop attribute dimensions in any schema except SYS, AUDSYS.                                                                                                                                     |
| <b>CLUSTERS:</b>               | —                                                                                                                                                                                               |
| CREATE ANY CLUSTER             | Create clusters in any schema except SYS, AUDSYS. Behaves similarly to CREATE ANY TABLE.<br>If the grantee is the schema owner, then grantee should have been granted CREATE CLUSTER privilege. |
| ALTER ANY CLUSTER              | Alter clusters in any schema except SYS, AUDSYS.                                                                                                                                                |
| DROP ANY CLUSTER               | Drop clusters in any schema except SYS, AUDSYS.                                                                                                                                                 |
| <b>DATA REDACTION:</b>         | —                                                                                                                                                                                               |
| EXEMPT REDACTION POLICY        | Bypass any existing Oracle Data Redaction policies and view actual data from tables or views on which Data Redaction policies are defined in the schema.                                        |
| <b>DIMENSIONS:</b>             | —                                                                                                                                                                                               |

|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CREATE ANY SYNONYM           | Create private synonyms in any schema except SYS, AUDSYS.<br>If the grantee is the schema owner, then grantee should have been granted CREATE SYNONYM privilege.                                                                                                 |
| DROP ANY SYNONYM             | Drop private synonyms in any schema except SYS,AUDSYS.                                                                                                                                                                                                           |
| <b>TABLES:</b>               | —                                                                                                                                                                                                                                                                |
| CREATE ANY TABLE             | Create a table in any schema except SYS, AUDSYS. The owner of the schema containing the table must have space quota on the tablespace to contain the table.<br>If the grantee is the schema owner, then grantee should have been granted CREATE TABLE privilege. |
| ALTER ANY TABLE              | Alter a table or view in any schema except SYS, AUDSYS.                                                                                                                                                                                                          |
| BACKUP ANY TABLE             | Use the Export utility to incrementally export objects from the schema of other users except SYS, AUDSYS.                                                                                                                                                        |
| DELETE ANY TABLE             | Delete rows from tables, table partitions, or views in any schema except SYS, AUDSYS.                                                                                                                                                                            |
| DROP ANY TABLE               | Drop or truncate tables or table partitions in any schema except SYS, AUDSYS.                                                                                                                                                                                    |
| INSERT ANY TABLE             | Insert rows into tables and views in any schema except SYS, AUDSYS.                                                                                                                                                                                              |
| LOCK ANY TABLE               | Lock tables and views in any schema except SYS, AUDSYS.                                                                                                                                                                                                          |
| READ ANY TABLE               | Query tables, views, or materialized views in any schema except SYS, AUDSYS.                                                                                                                                                                                     |
| SELECT ANY TABLE             | Query tables, views, or materialized views in any schema except SYS, AUDSYS. Obtain row locks using a SELECT ... FOR UPDATE.                                                                                                                                     |
| FLASHBACK ANY TABLE          | Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS, AUDSYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.                                                                                    |
| UPDATE ANY TABLE             | Update rows in tables and views in any schema except SYS, AUDSYS.                                                                                                                                                                                                |
| <b>TRIGGERS:</b>             | —                                                                                                                                                                                                                                                                |
| CREATE ANY TRIGGER           | Create database triggers in any schema except SYS, AUDSYS.<br>If the grantee is the schema owner, then grantee should have been granted CREATE TRIGGER privilege.                                                                                                |
| ALTER ANY TRIGGER            | Enable, disable, or compile database triggers in any schema except SYS, AUDSYS.                                                                                                                                                                                  |
| DROP ANY TRIGGER             | Drop database triggers in any schema except SYS, AUDSYS.                                                                                                                                                                                                         |
| <b>TYPES:</b>                | —                                                                                                                                                                                                                                                                |
| CREATE ANY TYPE              | Create object types and object type bodies in any schema except SYS, AUDSYS.<br>If the grantee is the schema owner, then grantee should have been granted CREATE TYPE privilege.                                                                                 |
| ALTER ANY TYPE               | Alter object types in any schema except SYS, AUDSYS.                                                                                                                                                                                                             |

**Table 18-3 (Cont.) Schema Privileges (Organized by the Operations Authorized)**

| Schema Privilege Name | Operations Authorized                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DROP ANY TYPE         | Drop object types and object type bodies in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                               |
| EXECUTE ANY TYPE      | Use and reference object types and collection types in any schema except SYS, AUDSYS, and invoke methods of an object type in any schema, except SYS, AUDSYS, if you make the grant to a specific user. If you grant EXECUTE ANY TYPE to a role, then users holding the enabled role will not be able to invoke methods of an object type in any schema. |
| UNDER ANY TYPE        | Create subtypes under any nonfinal object types.                                                                                                                                                                                                                                                                                                         |
| <b>IEWS:</b>          | —                                                                                                                                                                                                                                                                                                                                                        |
| CREATE ANY VIEW       | Create views in any schema except SYS, AUDSYS.<br>If the grantee is the schema owner, then grantee should have been granted CREATE VIEW privilege.                                                                                                                                                                                                       |
| DROP ANY VIEW         | Drop views in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                                                             |
| UNDER ANY VIEW        | Create subviews under any object views.                                                                                                                                                                                                                                                                                                                  |
| FLASHBACK ANY TABLE   | Issue a SQL Flashback Query on any table, view, or materialized view in any schema except SYS, AUDSYS. This privilege is not needed to execute the DBMS_FLASHBACK procedures.                                                                                                                                                                            |
| <b>MISCELLANEOUS:</b> | —                                                                                                                                                                                                                                                                                                                                                        |
| ANALYZE ANY           | Analyze a table, cluster, or index in any schema except SYS.                                                                                                                                                                                                                                                                                             |
| AUDIT ANY             | Audit an object in any schema, except SYS, AUDSYS, using AUDIT schema_objects statements.                                                                                                                                                                                                                                                                |
| COMMENT ANY TABLE     | Comment on a table, view, or column in any schema except SYS, AUDSYS.                                                                                                                                                                                                                                                                                    |
| EXEMPT ACCESS POLICY  | Bypass fine-grained access control.<br><b>Caution:</b> This is a very powerful system privilege, as it lets the grantee bypass application-driven security policies. Database administrators should use caution when granting this privilege.                                                                                                            |

## Examples

### Granting a System Privilege to a User: Example

To grant the CREATE SESSION system privilege to the sample user hr, allowing hr to log on to Oracle Database, issue the following statement:

```
GRANT CREATE SESSION
  TO hr;
```

### Assigning User Passwords When Granting a System Privilege: Example

Assume that user hr exists and user newuser does not exist. The following statement resets the user hr password to *password1*, creates user newuser with *password2*, and grants both users the CREATE SESSION system privilege:

```
GRANT CREATE SESSION
  TO hr, newuser IDENTIFIED BY password1, password2;
```

## Granting System Privileges to a Role: Example

The following statement grants appropriate system privileges to a data warehouse manager role, which was created in the "[Creating a Role: Example](#)":

```
GRANT
    CREATE ANY MATERIALIZED VIEW
    , ALTER ANY MATERIALIZED VIEW
    , DROP ANY MATERIALIZED VIEW
    , QUERY REWRITE
    , GLOBAL QUERY REWRITE
    TO dw_manager
    WITH ADMIN OPTION;
```

The `dw_manager` privilege domain now contains the system privileges related to materialized views.

## Granting a Role with the ADMIN OPTION: Example

To grant the `dw_manager` role with the `ADMIN OPTION` to the sample user `sh`, issue the following statement:

```
GRANT dw_manager
    TO sh
    WITH ADMIN OPTION;
```

User `sh` can now perform the following operations with the `dw_manager` role:

- Enable the role and exercise any privileges in the privilege domain of the role, including the `CREATE MATERIALIZED VIEW` system privilege
- Grant and revoke the role to and from other users
- Drop the role
- Grant and revoke the `dw_manager` role to and from program units in the `sh` schema

## Granting a Role with the DELEGATE OPTION: Example

To grant the `dw_manager` role with the `DELEGATE OPTION` to the sample user `sh`, issue the following statement:

```
GRANT dw_manager
    TO sh
    WITH DELEGATE OPTION;
```

User `sh` can now grant and revoke the `dw_manager` role to and from program units in the `sh` schema.

## Granting Object Privileges to a Role: Example

The following example grants the `SELECT` object privileges to a data warehouse user role, which was created in the "[Creating a Role: Example](#)":

```
GRANT SELECT ON sh.sales TO warehouse_user;
```

## Granting a Role to a Role: Example

The following statement grants the `warehouse_user` role to the `dw_manager` role. Both roles were created in the "[Creating a Role: Example](#)":

```
GRANT warehouse_user TO dw_manager;
```

The dw\_manager role now contains all of the privileges in the domain of the warehouse\_user role.

### Granting an Object Privilege on a User: Example

To grant the INHERIT PRIVILEGES object privilege on user sh to user hr, issue the following statement:

```
GRANT INHERIT PRIVILEGES ON USER sh TO hr;
```

### Granting an Object Privilege on a Directory: Example

To grant READ on directory bfile\_dir to user hr, with the GRANT OPTION, issue the following statement:

```
GRANT READ ON DIRECTORY bfile_dir TO hr
    WITH GRANT OPTION;
```

### Granting Object Privileges on a Table to a User: Example

To grant all privileges on the table oe.bonuses, which was created in "[Merging into a Table: Example](#)", to the user hr with the GRANT OPTION, issue the following statement:

```
GRANT ALL ON bonuses TO hr
    WITH GRANT OPTION;
```

The user hr can subsequently perform the following operations:

- Exercise any privilege on the bonuses table
- Grant any privilege on the bonuses table to another user or role

### Granting Object Privileges on a View: Example

To grant SELECT and UPDATE privileges on the view emp\_view, which was created in "[Creating a View: Example](#)", to all users, issue the following statement:

```
GRANT SELECT, UPDATE
    ON emp_view TO PUBLIC;
```

All users can subsequently query and update the view of employee details.

### Granting Object Privileges to a Sequence in Another Schema: Example

To grant SELECT privilege on the customers\_seq sequence in the schema oe to the user hr, issue the following statement:

```
GRANT SELECT
    ON oe.customers_seq TO hr;
```

The user hr can subsequently generate the next value of the sequence with the following statement:

```
SELECT oe.customers_seq.NEXTVAL
    FROM DUAL;
```

### Granting Multiple Object Privileges on Individual Columns: Example

To grant to user oe the REFERENCES privilege on the employee\_id column and the UPDATE privilege on the employee\_id, salary, and commission\_pct columns of the employees table in the schema hr, issue the following statement:

```
GRANT REFERENCES (employee_id),
   UPDATE (employee_id, salary, commission_pct)
ON hr.employees
TO oe;
```

The user `oe` can subsequently update values of the `employee_id`, `salary`, and `commission_pct` columns. User `oe` can also define referential integrity constraints that refer to the `employee_id` column. However, because the `GRANT` statement lists only these columns, `oe` cannot perform operations on any of the other columns of the `employees` table.

For example, `oe` can create a table with a constraint:

```
CREATE TABLE dependent
  (dependno    NUMBER,
   dependname  VARCHAR2(10),
   employee    NUMBER
  CONSTRAINT in_emp REFERENCES hr.employees(employee_id) );
```

The constraint `in_emp` ensures that all dependents in the `dependent` table correspond to an employee in the `employees` table in the schema `hr`.

## INSERT

### Purpose

Use the `INSERT` statement to add rows to a table, the base table of a view, a partition of a partitioned table or a subpartition of a composite-partitioned table, or an object table or the base table of an object view.

### Prerequisites

For you to insert rows into a table, the table must be in your own schema or you must have the `INSERT` object privilege on the table.

For you to insert rows into the base table of a view, the owner of the schema containing the view must have the `INSERT` object privilege on the base table. Also, if the view is in a schema other than your own, then you must have the `INSERT` object privilege on the view.

If you have the `INSERT ANY TABLE` system privilege, then you can also insert rows into any table or the base table of any view.

You must also have the `READ` or `SELECT` object privilege on the table into which you want to insert rows if the table is on a remote database.

### Conventional and Direct-Path INSERT

You can use the `INSERT` statement to insert data into a table, partition, or view in two ways: conventional `INSERT` and direct-path `INSERT`. When you issue a conventional `INSERT` statement, Oracle Database reuses free space in the table into which you are inserting and maintains referential integrity constraints. With direct-path `INSERT`, the database appends the inserted data after existing data in the table. Data is written directly into data files, bypassing the buffer cache. Free space in the existing data is not reused. This alternative enhances performance during insert operations and is similar to the functionality of the Oracle direct-path loader utility, `SQL*Loader`. When you insert into a table that has been created in parallel mode, direct-path `INSERT` is the default.

The manner in which the database generates redo and undo data depends in part on whether you are using conventional or direct-path `INSERT`:

- Conventional `INSERT` always generates maximal redo and undo for changes to both data and metadata, regardless of the logging setting of the table and the archivelog and force logging settings of the database.
- Direct-path `INSERT` generates both redo and undo for *metadata* changes, because these are needed for operation recovery. For *data* changes, undo and redo are generated as follows:
  - Direct-path `INSERT` always bypasses undo generation for data changes.
  - If the database is not in `ARCHIVELOG` or `FORCE LOGGING` mode, then no redo is generated for data changes, regardless of the logging setting of the table.
  - If the database is in `ARCHIVELOG` mode (but not in `FORCE LOGGING` mode), then direct-path `INSERT` generates data redo for `LOGGING` tables but not for `NOLOGGING` tables.
  - If the database is in `ARCHIVELOG` and `FORCE LOGGING` mode, then direct-path SQL generate data redo for both `LOGGING` and `NOLOGGING` tables.

Direct-path `INSERT` is subject to a number of restrictions. If any of these restrictions is violated, then Oracle Database executes conventional `INSERT` serially without returning any message, unless otherwise noted:

- You can have multiple direct-path `INSERT` statements in a single transaction, with or without other DML statements. However, after one DML statement alters a particular table, partition, or index, no other DML statement in the transaction can access that table, partition, or index.
- Queries that access the same table, partition, or index are allowed before the direct-path `INSERT` statement, but not after it.
- If any serial or parallel statement attempts to access a table that has already been modified by a direct-path `INSERT` in the same transaction, then the database returns an error and rejects the statement.
- The target table cannot be of a cluster.
- The target table cannot contain object type columns.
- Direct-path `INSERT` is not supported for an index-organized table (IOT) if it has a mapping table, or if it is reference by a materialized view.
- Direct-path `INSERT` into a single partition of an index-organized table (IOT), into a partitioned IOT with only one partition, or into an IOT that is not partitioned, will be done serially, even if the IOT was created in parallel mode or you specify the `APPEND` or `APPEND_VALUES` hint. However, direct-path `INSERT` operations into a partitioned IOT will honor parallel mode as long as the partition-extended name is not used and the IOT has more than one partition.
- The target table cannot have any triggers or referential integrity constraints defined on it.
- The target table cannot be replicated.
- A transaction containing a direct-path `INSERT` statement cannot be or become distributed.

*conditional\_insert\_clause ::=*

(*insert\_into\_clause ::=, insert\_values\_clause ::=*)

*DML\_table\_expression\_clause ::=*

(*partition\_extension\_clause::=*, *subquery::=*—part of SELECT, *subquery\_restriction\_clause::=*, *table\_collection\_expression::=*)

*partition\_extension\_clause::=*

*subquery\_restriction\_clause::=*

*table\_collection\_expression::=*

*error\_logging\_clause::=*

## Semantics

### hint

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

For a multi-table insert, if you specify the `PARALLEL` hint for any target table, then the entire multi-table insert statement is parallelized even if the target tables have not been created or altered with `PARALLEL` specified. If you do not specify the `PARALLEL` hint, then the insert

operation will not be parallelized unless all target tables were created or altered with `PARALLEL` specified.

 **See Also:**

- "[Hints](#)" for the syntax and description of hints
- "[Restrictions on Multi-Table Inserts](#)"

### ***single\_table\_insert***

In a **single-table insert**, you insert values into one row of a table, view, or materialized view by specifying values explicitly or by retrieving the values through a subquery.

You can use the `flashback_query_clause` in `subquery` to insert past data into `table`. Refer to the [`flashback\_query\_clause`](#) of `SELECT` for more information on this clause.

#### **Restriction on Single-Table Inserts**

If you retrieve values through a subquery, then the select list of the subquery must have the same number of columns as the column list of the `INSERT` statement. If you omit the column list, then the subquery must provide values for every column in the table.

 **See Also:**

- "[Inserting Values into Tables: Examples](#)"

### ***insert\_into\_clause***

Use the `INSERT INTO` clause to specify the target object or objects into which the database is to insert data.

Directory-based sharding uses the same partition extension syntax as system-based sharding.

### ***DML\_table\_expression\_clause***

Use the `INTO DML_table_expression_clause` to specify the objects into which data is being inserted.

### ***schema***

Specify the schema containing the table, view, or materialized view. If you omit `schema`, then the database assumes the object is in your own schema.

### ***table | view | materialized\_view | subquery***

Specify the name of the table or object table, view or object view, materialized view, or the column or columns returned by a subquery, into which rows are to be inserted. If you specify a view or object view, then the database inserts rows into the base table of the view.

You cannot insert rows into a read-only materialized view. If you insert rows into a writable materialized view, then the database inserts the rows into the underlying container table. However, the insertions are overwritten at the next refresh operation. If you insert rows into an updatable materialized view that is part of a materialized view group, then the database also inserts the corresponding rows into the master table.

If any value to be inserted is a `REF` to an object table, and if the object table has a primary key object identifier, then the column into which you insert the `REF` must be a `REF` column with a referential integrity or `SCOPE` constraint to the object table.

If `table`, or the base table of `view`, contains one or more domain index columns, then this statement executes the appropriate indextype insert routine.

Issuing an `INSERT` statement against a table fires any `INSERT` triggers defined on the table.

#### See Also:

*Oracle Database Data Cartridge Developer's Guide* for more information on these routines

### Restrictions on the `DML_table_expression_clause`

This clause is subject to the following restrictions:

- You cannot execute this statement if `table` or the base table of `view` contains any domain indexes marked `IN_PROGRESS` or `FAILED`.
- You cannot insert into a partition if any affected index partitions are marked `UNUSABLE`.
- With regard to the `ORDER BY` clause of the `subquery` in the `DML_table_expression_clause`, ordering is guaranteed only for the rows being inserted, and only within each extent of the table. Ordering of new rows with respect to existing rows is not guaranteed.
- If a view was created using the `WITH CHECK OPTION`, then you can insert into the view only rows that satisfy the defining query of the view.
- If a view was created using a single base table, then you can insert rows into the view and then retrieve those values using the `returning_clause`.
- You cannot insert rows into a view except with `INSTEAD OF` triggers if the defining query of the view contains one of the following constructs:

A set operator

A `DISTINCT` operator

An aggregate or analytic function

A `GROUP BY`, `ORDER BY`, `MODEL`, `CONNECT BY`, or `START WITH` clause

A collection expression in a `SELECT` list

A subquery in a `SELECT` list

A subquery designated `WITH READ ONLY`

Joins, with some exceptions, as documented in *Oracle Database Administrator's Guide*

- If you specify an index, index partition, or index subpartition that has been marked `UNUSABLE`, then the `INSERT` statement will fail unless the `SKIP_UNUSABLE_INDEXES` session parameter has been set to `TRUE`. Refer to [ALTER SESSION](#) for information on the `SKIP_UNUSABLE_INDEXES` session parameter.

#### ***partition\_extension\_clause***

Specify the name or partition key value of the partition or subpartition within `table`, or the base table of `view`, targeted for inserts.

If a row to be inserted does not map into a specified partition or subpartition, then the database returns an error.

#### **Restriction on Target Partitions and Subpartitions**

This clause is not valid for object tables or object views.

##### **See Also:**

["References to Partitioned Tables and Indexes"](#)

#### ***dblink***

Specify a complete or partial name of a database link to a remote database where the table or view is located. You can insert rows into a remote table or view only if you are using Oracle Database distributed functionality.

If you omit `dblink`, then Oracle Database assumes that the table or view is on the local database.

##### **Note:**

Starting with Oracle Database 12c Release 2 (12.2), the `INSERT` statement accepts remote LOB locators as bind variables. Refer to the “Distributed LOBs” chapter in *Oracle Database SecureFiles and Large Objects Developer’s Guide* for more information.

##### **See Also:**

- ["Syntax for Schema Objects and Parts in SQL Statements"](#) and ["References to Objects in Remote Databases"](#) for information on referring to database links
- ["Inserting into a Remote Database: Example"](#)

#### ***subquery\_restriction\_clause***

Use the `subquery_restriction_clause` to restrict the subquery in one of the following ways:

## WITH READ ONLY

Specify `WITH READ ONLY` to indicate that the table or view cannot be updated.

## WITH CHECK OPTION

Specify `WITH CHECK OPTION` to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the `FROM` clause but not in subquery in the `WHERE` clause.

### CONSTRAINT *constraint*

Specify the name of the `CHECK OPTION` constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form `SYS_Cn`, where *n* is an integer that makes the constraint name unique within the database.

#### See Also:

["Using the WITH CHECK OPTION Clause: Example"](#)

## *table\_collection\_expression*

The `table_collection_expression` lets you inform Oracle that the value of `collection_expression` should be treated as a table for purposes of query and DML operations. The `collection_expression` can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called **collection unnesting**.

The optional plus (+) is relevant if you are joining the `TABLE` collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

#### Note:

In earlier releases of Oracle, when `collection_expression` was a subquery, `table_collection_expression` was expressed as `THE subquery`. That usage is now deprecated.

#### See Also:

["Table Collections: Examples"](#)

## *t\_alias*

Specify a **correlation name**, which is an alias for the table, view, materialized view, or subquery to be referenced elsewhere in the statement.

## Restriction on Table Aliases

You cannot specify *t\_alias* during a multi-table insert.

### **column**

Specify a column of the table, view, or materialized view. In the inserted row, each column in this list is assigned a value from the *values\_clause* or the subquery. If you want to assign a value to an INVISIBLE column, then you must include the column in this list.

If you omit one or more of the table's columns from this list, then the column value of that column for the inserted row is the column default value as specified when the table was created or last altered. If any omitted column has a NOT NULL constraint and no default value, then the database returns an error indicating that the constraint has been violated and rolls back the *INSERT* statement. Refer to [CREATE TABLE](#) for more information on default column values.

If you omit the column list altogether, then the *values\_clause* or query must specify values for all columns in the table.

### **values\_clause**

For a **single-table insert** operation, specify a row of values to be inserted into the table or view. You must specify a value in the *values\_clause* for each column in the column list. If you omit the column list, then the *values\_clause* must provide values for every column in the table.

For a **multi-table insert** operation, each expression in the *values\_clause* must refer to columns returned by the select list of the subquery. If you omit the *values\_clause*, then the select list of the subquery determines the values to be inserted, so it must have the same number of columns as the column list of the corresponding *insert\_into\_clause*. If you do not specify a column list in the *insert\_into\_clause*, then the computed row must provide values for all columns in the target table.

For both types of insert operations, if you specify a column list in the *insert\_into\_clause*, then the database assigns to each column in the list a corresponding value from the *values\_clause* or the subquery. You can specify DEFAULT for any value in the *values\_clause*. If you have specified a default value for the corresponding column of the table or view, then that value is inserted. If no default value for the corresponding column has been specified, then the database inserts null. Refer to "About SQL Expressions" and [SELECT](#) for syntax of valid expressions.

## Restrictions on Inserted Values

Values are subject to the following restrictions:

- You cannot insert a BFILE value until you have initialized the BFILE locator to null or to a directory name and filename.
- When inserting into a list-partitioned table, you cannot insert a value into the partitioning key column that does not already exist in the *partition\_key\_value* list of one of the partitions.
- You cannot specify DEFAULT when inserting into a view.
- If you insert string literals into a RAW column, then during subsequent queries Oracle Database will perform a full table scan rather than using any index that might exist on the RAW column.

- Default values for columns are disallowed in row value expressions.

### ***returning\_clause***

The returning clause retrieves the rows affected by a DML statement. You can specify this clause for tables and materialized views and for views with a single base table.

When operating on a single row, a DML statement with a *returning\_clause* can retrieve column expressions using the affected row, rowid, and REFs to the affected row and store them in host variables or PL/SQL variables.

When operating on multiple rows, a DML statement with the *returning\_clause* stores values from expressions, rowids, and REFs involving the affected rows in bind arrays.

### ***expr***

Each item in the *expr* list must be a valid expression syntax.

### **INTO**

The **INTO** clause indicates that the values of the changed rows are to be stored in the variable(s) specified in *data\_item* list.

### ***data\_item***

Each *data\_item* is a host variable or PL/SQL variable that stores the retrieved *expr* value.

For each expression in the RETURNING list, you must specify a corresponding type-compatible PL/SQL variable or host variable in the INTO list.

### **Restrictions**

The following restrictions apply to the RETURNING clause:

- The *expr* is restricted as follows:
  - For UPDATE and DELETE statements each *expr* must be a simple expression or a single-set aggregate function expression. You cannot combine simple expressions and single-set aggregate function expressions in the same *returning\_clause*. For INSERT statements, each *expr* must be a simple expression. Aggregate functions are not supported in an INSERT statement RETURNING clause.
  - Single-set aggregate function expressions cannot include the DISTINCT keyword.

- If the `expr` list contains a primary key column or other NOT NULL column, then the update statement fails if the table has a BEFORE UPDATE trigger defined on it.
- You cannot specify the `returning_clause` for a multi-table insert.
- You cannot use this clause with parallel DML or with remote objects.
- You cannot retrieve LONG types with this clause.
- You cannot specify this clause for a view on which an INSTEAD OF trigger has been defined.

#### See Also:

*Oracle Database PL/SQL Language Reference* for information on using the BULK COLLECT clause to return multiple values to collection variables

### ***multi\_table\_insert***

In a **multi-table insert**, you insert rows returned from the evaluation of a subquery into one or more tables.

Table aliases are not defined by the select list of the subquery. Therefore, they are not visible in the clauses dependent on the select list. For example, this can happen when trying to refer to an object column in an expression. To use an expression with a table alias, you must put the expression into the select list with a column alias, and then refer to the column alias in the VALUES clause or WHEN condition of the multi-table insert.

#### **ALL *into\_clause***

Specify ALL followed by multiple `insert_into_clauses` to perform an **unconditional multi-table insert**. Oracle Database executes each `insert_into_clause` once for each row returned by the subquery.

#### **Restrictions Using INSERT ALL**

- The maximum number of rows you can insert into a table with 4096 columns is 15.
- The maximum number of rows you can insert into a table with 1000 columns is 65.
- The maximum row limit for tables with fewer columns is not constant and may vary.

#### ***conditional\_insert\_clause***

Specify the `conditional_insert_clause` to perform a **conditional multi-table insert**. Oracle Database filters each `insert_into_clause` through the corresponding WHEN condition, which determines whether that `insert_into_clause` is executed. Each expression in the WHEN condition must refer to columns returned by the select list of the subquery. A single multi-table insert statement can contain up to 127 WHEN clauses.

#### **ALL**

If you specify ALL, the default value, then the database evaluates each WHEN clause regardless of the results of the evaluation of any other WHEN clause. For each WHEN clause whose condition evaluates to true, the database executes the corresponding INTO clause list.

## FIRST

If you specify FIRST, then the database evaluates each WHEN clause in the order in which it appears in the statement. For the first WHEN clause that evaluates to true, the database executes the corresponding INTO clause and skips subsequent WHEN clauses for the given row.

## ELSE clause

For a given row, if no WHEN clause evaluates to true, then:

- If you have specified an ELSE clause, then the database executes the INTO clause list associated with the ELSE clause.
- If you did not specify an else clause, then the database takes no action for that row.

### See Also:

"[Multi-Table Inserts: Examples](#)"

## Restrictions on Multi-Table Inserts

multi-table inserts are subject to the following restrictions:

- You can perform multi-table inserts only on tables, not on views or materialized views.
- You cannot perform a multi-table insert into a remote table.
- You cannot specify a TABLE collection expression when performing a multi-table insert.
- multi-table inserts are not parallelized if any target table is index organized or if any target table has a bitmap index defined on it.
- Plan stability is not supported for multi-table insert statements.
- The subquery of the multitable insert statement cannot use a sequence. For rules pertaining to sequences, see [How to Use Sequence Values](#)

## *subquery*

Specify a subquery that returns rows that are inserted into the table. The subquery can refer to any table, view, or materialized view, including the target tables of the INSERT statement. If the subquery selects no rows, then the database inserts no rows into the table.

You can use *subquery* in combination with the TO\_LOB function to convert the values in a LONG column to LOB values in another column in the same or another table.

- To migrate LONG values to LOB values in another column in a view, you must perform the migration on the base table and then add the LOB column to the view.
- To migrate LONG values on a remote table to LOB values in a local table, you must perform the migration on the remote table using the TO\_LOB function, and then perform an INSERT ... *subquery* operation to copy the LOB values from the remote table into the local table.

## Notes on Inserting with a Subquery

The following notes apply when inserting with a subquery:

- If *subquery* returns the partial or total equivalent of a materialized view, then the database may use the materialized view for query rewrite in place of one or more tables specified in *subquery*.

 **See Also:**

*Oracle Database Data Warehousing Guide* for more information on materialized views and query rewrite

- If *subquery* refers to remote objects, then the `INSERT` operation can run in parallel as long as the reference does not loop back to an object on the local database. However, if the *subquery* in the `DML_table_expression_clause` refers to any remote objects, then the `INSERT` operation will run serially without notification. See [parallel\\_clause](#) for more information.
- If *subquery* includes an `ORDER BY` clause, then it will override row ordering specified using attribute clustering table properties.

 **See Also:**

- "[Inserting Values with a Subquery: Example](#)"
- [BFILENAME](#) for an example of inserting into a `BFILE`
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for information on initializing `BFILES`
- "[About SQL Expressions](#)" and `SELECT` for syntax of valid expressions

***error\_logging\_clause***

The *error\_logging\_clause* lets you capture DML errors and the log column values of the affected rows and save them in an error logging table.

**INTO table**

Specify the name of the error logging table. If you omit this clause, then the database assigns the default name generated by the `DBMS_ERRLOG` package. The default error log table name is `ERR$` followed by the first 25 characters of the name of the table upon which the DML operation is being executed.

***simple\_expression***

Specify the value to be used as a statement tag, so that you can identify the errors from this statement in the error logging table. The expression can be either a text literal, a number literal, or a general SQL expression such as a bind variable. You can also use a function expression if you convert it to a text literal — for example, `TO_CHAR(SYSDATE)`.

**REJECT LIMIT**

This clause lets you specify an integer as an upper limit for the number of errors to be logged before the statement terminates and rolls back any changes made by the

statement. The default rejection limit is zero. For parallel DML operations, the reject limit is applied to each parallel server.

### Restrictions on DML Error Logging

- The following conditions cause the statement to fail and roll back without invoking the error logging capability:
  - Violated deferred constraints.
  - Any direct-path `INSERT` or `MERGE` operation that raises a unique constraint or index violation.
  - Any update operation `UPDATE` or `MERGE` that raises a unique constraint or index violation.
- You cannot track errors in the error logging table for `LONG`, `LOB`, or object type columns. However, the table that is the target of the DML operation can contain these types of columns.
  - If you create or modify the corresponding error logging table so that it contains a column of an unsupported type, and if the name of that column corresponds to an unsupported column in the target DML table, then the DML statement fails at parse time.
  - If the error logging table does not contain any unsupported column types, then all DML errors are logged until the reject limit of errors is reached. For rows on which errors occur, column values with corresponding columns in the error logging table are logged along with the control information.

#### See Also:

- *Oracle Database PL/SQL Packages and Types Reference* for information on using the `create_error_log` procedure of the `DBMS_ERRLOG` package and *Oracle Database Administrator's Guide* for general information on DML error logging.

## Examples

### Inserting Values into Tables: Examples

The following statement inserts a row into the sample table `departments`:

```
INSERT INTO departments
    VALUES (280, 'Recreation', 121, 1700);
```

If the `departments` table had been created with a default value of 121 for the `manager_id` column, then you could issue the same statement as follows:

```
INSERT INTO departments
    VALUES (280, 'Recreation', DEFAULT, 1700);
```

The following statement inserts a row with six columns into the `employees` table. One of these columns is assigned `NULL` and another is assigned a number in scientific notation:

```
INSERT INTO employees (employee_id, last_name, email,
    hire_date, job_id, salary, commission_pct)
```

```
VALUES (207, 'Gregory', 'pgregory@example.com',
       sysdate, 'PU_CLERK', 1.2E3, NULL);
```

The following statement has the same effect as the preceding example, but uses a subquery in the *DML\_table\_expression\_clause*:

```
INSERT INTO
  (SELECT employee_id, last_name, email, hire_date, job_id,
   salary, commission_pct FROM employees)
VALUES (207, 'Gregory', 'pgregory@example.com',
       sysdate, 'PU_CLERK', 1.2E3, NULL);
```

### Inserting Values with a Subquery: Example

The following statement copies employees whose commission exceeds 25% of their salary into the *bonuses* table, which was created in "[Merging into a Table: Example](#)":

```
INSERT INTO bonuses
  SELECT employee_id, salary*1.1
    FROM employees
   WHERE commission_pct > 0.25;
```

### Inserting Into a Table with Error Logging: Example

The following statements create a *raises* table in the sample schema *hr*, create an error logging table using the *DBMS\_ERRLOG* package, and populate the *raises* table with data from the *employees* table. One of the inserts violates the check constraint on *raises*, and that row can be seen in *errlog*. If more than ten errors had occurred, then the statement would have aborted, rolling back any insertions made:

```
CREATE TABLE raises (emp_id NUMBER, sal NUMBER
  CONSTRAINT check_sal CHECK(sal > 8000));

EXECUTE DBMS_ERRLOG.CREATE_ERROR_LOG('raises', 'errlog');

INSERT INTO raises
  SELECT employee_id, salary*1.1 FROM employees
  WHERE commission_pct > .2
  LOG ERRORS INTO errlog ('my_bad') REJECT LIMIT 10;

SELECT ORA_ERR_MESG$, ORA_ERR_TAG$, emp_id, sal FROM errlog;

ORA_ERR_MESG$          ORA_ERR_TAG$          EMP_ID SAL
-----  -----
ORA-02290: check constraint my_bad           161     7700
(HR.SYS_C004266) violated
```

### Inserting into a Remote Database: Example

The following statement inserts a row into the *employees* table owned by the user *hr* on the database accessible by the database link *remote*:

```
INSERT INTO employees@remote
  VALUES (8002, 'Juan', 'Fernandez', 'juanf@example.com', NULL,
         TO_DATE('04-OCT-1992', 'DD-MON-YYYY'), 'SH_CLERK', 3000,
         NULL, 121, 20);
```

### Inserting Sequence Values: Example

The following statement inserts a new row containing the next value of the *departments\_seq* sequence into the *departments* table:

---

```
INSERT INTO departments
    VALUES  (departments_seq.nextval, 'Entertainment', 162, 1400);
```

### Inserting Using Bind Variables: Example

The following example returns the values of the inserted rows into output bind variables `:bnd1` and `:bnd2`. The bind variables must first be declared.

```
INSERT INTO employees
    (employee_id, last_name, email, hire_date, job_id, salary)
VALUES
    (employees_seq.nextval, 'Doe', 'john.doe@example.com',
     SYSDATE, 'SH_CLERK', 2400)
RETURNING salary*12, job_id INTO :bnd1, :bnd2;
```

### Inserting into a Substitutable Tables and Columns: Examples

The following example inserts into the `persons` table, which is created in "[Substitutable Table and Column Examples](#)". The first statement uses the root type `person_t`. The second insert uses the `employee_t` subtype of `person_t`, and the third insert uses the `part_time_emp_t` subtype of `employee_t`:

```
INSERT INTO persons VALUES (person_t('Bob', 1234));
INSERT INTO persons VALUES (employee_t('Joe', 32456, 12, 100000));
INSERT INTO persons VALUES (
    part_time_emp_t('Tim', 5678, 13, 1000, 20));
```

The following example inserts into the `books` table, which was created in "[Substitutable Table and Column Examples](#)". Notice that specification of the attribute values is identical to that for the substitutable table example:

```
INSERT INTO books VALUES (
    'An Autobiography', person_t('Bob', 1234));
INSERT INTO books VALUES (
    'Business Rules', employee_t('Joe', 3456, 12, 10000));
INSERT INTO books VALUES (
    'Mixing School and Work',
    part_time_emp_t('Tim', 5678, 13, 1000, 20));
```

You can extract data from substitutable tables and columns using built-in functions and conditions. For examples, see the functions `TREAT` and `SYS_TYPEID`, and "["IS OF type Condition"](#)".

### Inserting Using the TO\_LOB Function: Example

The following example copies `LONG` data to a LOB column in the following `long_tab` table:

```
CREATE TABLE long_tab (pic_id NUMBER, long_pics LONG RAW);
```

First you must create a table with a LOB.

```
CREATE TABLE lob_tab (pic_id NUMBER, lob_pics BLOB);
```

Next, use an `INSERT ... SELECT` statement to copy the data in all rows for the `LONG` column into the newly created LOB column:

```
INSERT INTO lob_tab
    SELECT pic_id, TO_LOB(long_pics) FROM long_tab;
```

When you are confident that the migration has been successful, you can drop the `long_pics` table. Alternatively, if the table contains other columns, then you can simply drop the `LONG` column from the table as follows:

```
ALTER TABLE long_tab DROP COLUMN long_pics;
```

### Multi-Table Inserts: Examples

The following example uses the multi-table insert syntax to insert into the sample table `sh.sales` some data from an input table with a different structure.

#### Note:

A number of `NOT NULL` constraints on the `sales` table have been disabled for purposes of this example, because the example ignores a number of table columns for the sake of brevity.

The input table looks like this:

```
SELECT * FROM sales_input_table;
```

| PRODUCT_ID | CUSTOMER_ID | WEEKLY_ST | SALES_SUN | SALES_MON | SALES_TUE | SALES_WED | SALES_THU | SALES_FRI | SALES_SAT |
|------------|-------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| 111        | 222         | 01-OCT-00 | 100       | 200       | 300       | 400       | 500       | 600       | 700       |
| 222        | 333         | 08-OCT-00 | 200       | 300       | 400       | 500       | 600       | 700       | 800       |
| 333        | 444         | 15-OCT-00 | 300       | 400       | 500       | 600       | 700       | 800       | 900       |

The multi-table insert statement looks like this:

```
INSERT ALL
    INTO sales (prod_id, cust_id, time_id, amount)
        VALUES (product_id, customer_id, weekly_start_date, sales_sun)
    INTO sales (prod_id, cust_id, time_id, amount)
        VALUES (product_id, customer_id, weekly_start_date+1, sales_mon)
    INTO sales (prod_id, cust_id, time_id, amount)
        VALUES (product_id, customer_id, weekly_start_date+2, sales_tue)
    INTO sales (prod_id, cust_id, time_id, amount)
        VALUES (product_id, customer_id, weekly_start_date+3, sales_wed)
    INTO sales (prod_id, cust_id, time_id, amount)
        VALUES (product_id, customer_id, weekly_start_date+4, sales_thu)
    INTO sales (prod_id, cust_id, time_id, amount)
        VALUES (product_id, customer_id, weekly_start_date+5, sales_fri)
    INTO sales (prod_id, cust_id, time_id, amount)
        VALUES (product_id, customer_id, weekly_start_date+6, sales_sat)
    SELECT product_id, customer_id, weekly_start_date, sales_sun,
          sales_mon, sales_tue, sales_wed, sales_thu, sales_fri, sales_sat
    FROM sales_input_table;
```

Assuming these are the only rows in the `sales` table, the contents now look like this:

```
SELECT * FROM sales
ORDER BY prod_id, cust_id, time_id;
```

| PROD_ID | CUST_ID | TIME_ID   | C | PROMO_ID | QUANTITY SOLD | AMOUNT | COST |
|---------|---------|-----------|---|----------|---------------|--------|------|
| 111     | 222     | 01-OCT-00 |   |          |               | 100    |      |
| 111     | 222     | 02-OCT-00 |   |          |               | 200    |      |

|     |     |           |     |
|-----|-----|-----------|-----|
| 111 | 222 | 03-OCT-00 | 300 |
| 111 | 222 | 04-OCT-00 | 400 |
| 111 | 222 | 05-OCT-00 | 500 |
| 111 | 222 | 06-OCT-00 | 600 |
| 111 | 222 | 07-OCT-00 | 700 |
| 222 | 333 | 08-OCT-00 | 200 |
| 222 | 333 | 09-OCT-00 | 300 |
| 222 | 333 | 10-OCT-00 | 400 |
| 222 | 333 | 11-OCT-00 | 500 |
| 222 | 333 | 12-OCT-00 | 600 |
| 222 | 333 | 13-OCT-00 | 700 |
| 222 | 333 | 14-OCT-00 | 800 |
| 333 | 444 | 15-OCT-00 | 300 |
| 333 | 444 | 16-OCT-00 | 400 |
| 333 | 444 | 17-OCT-00 | 500 |
| 333 | 444 | 18-OCT-00 | 600 |
| 333 | 444 | 19-OCT-00 | 700 |
| 333 | 444 | 20-OCT-00 | 800 |
| 333 | 444 | 21-OCT-00 | 900 |

The next examples insert into multiple tables. Suppose you want to provide to sales representatives some information on orders of various sizes. The following example creates tables for small, medium, large, and special orders and populates those tables with data from the sample table oe.orders:

```

CREATE TABLE small_orders
  (order_id      NUMBER(12)    NOT NULL,
   customer_id   NUMBER(6)     NOT NULL,
   order_total   NUMBER(8,2),
   sales_rep_id  NUMBER(6)
  );

CREATE TABLE medium_orders AS SELECT * FROM small_orders;

CREATE TABLE large_orders AS SELECT * FROM small_orders;

CREATE TABLE special_orders
  (order_id      NUMBER(12)    NOT NULL,
   customer_id   NUMBER(6)     NOT NULL,
   order_total   NUMBER(8,2),
   sales_rep_id  NUMBER(6),
   credit_limit  NUMBER(9,2),
   cust_email    VARCHAR2(40)
  );

```

The first multi-table insert populates only the tables for small, medium, and large orders:

```

INSERT ALL
  WHEN order_total <= 100000 THEN
    INTO small_orders
  WHEN order_total > 1000000 AND order_total <= 200000 THEN
    INTO medium_orders
  WHEN order_total > 200000 THEN
    INTO large_orders
  SELECT order_id, order_total, sales_rep_id, customer_id
    FROM orders;

```

You can accomplish the same thing using the ELSE clause in place of the insert into the large\_orders table:

```
INSERT ALL
    WHEN order_total <= 100000 THEN
        INTO small_orders
    WHEN order_total > 100000 AND order_total <= 200000 THEN
        INTO medium_orders
    ELSE
        INTO large_orders
    SELECT order_id, order_total, sales_rep_id, customer_id
    FROM orders;
```

The next example inserts into the small, medium, and large tables, as in the preceding example, and also puts orders greater than 290,000 into the `special_orders` table. This table also shows how to use column aliases to simplify the statement:

```
INSERT ALL
    WHEN ottl <= 100000 THEN
        INTO small_orders
            VALUES(oid, ottl, sid, cid)
    WHEN ottl > 100000 and ottl <= 200000 THEN
        INTO medium_orders
            VALUES(oid, ottl, sid, cid)
    WHEN ottl > 200000 THEN
        into large_orders
            VALUES(oid, ottl, sid, cid)
    WHEN ottl > 290000 THEN
        INTO special_orders
    SELECT o.order_id oid, o.customer_id cid, o.order_total ottl,
        o.sales_rep_id sid, c.credit_limit cl, c.cust_email cem
    FROM orders o, customers c
    WHERE o.customer_id = c.customer_id;
```

Finally, the next example uses the `FIRST` clause to put orders greater than 290,000 into the `special_orders` table and exclude those orders from the `large_orders` table:

```
INSERT FIRST
    WHEN ottl <= 100000 THEN
        INTO small_orders
            VALUES(oid, ottl, sid, cid)
    WHEN ottl > 100000 and ottl <= 200000 THEN
        INTO medium_orders
            VALUES(oid, ottl, sid, cid)
    WHEN ottl > 290000 THEN
        INTO special_orders
    WHEN ottl > 200000 THEN
        INTO large_orders
            VALUES(oid, ottl, sid, cid)
    SELECT o.order_id oid, o.customer_id cid, o.order_total ottl,
        o.sales_rep_id sid, c.credit_limit cl, c.cust_email cem
    FROM orders o, customers c
    WHERE o.customer_id = c.customer_id;
```

### Inserting Multiple Rows Using a Single Statement: Example

The following statements create three tables named people, patients and staff:

```
CREATE TABLE people (
    person_id    INTEGER NOT NULL PRIMARY KEY,
    given_name   VARCHAR2(100) NOT NULL,
    family_name  VARCHAR2(100) NOT NULL,
    title        VARCHAR2(20),
    birth_date   DATE
```

```
);

CREATE TABLE patients (
    patient_id          INTEGER NOT NULL PRIMARY KEY REFERENCES people (person_id),
    last_admission_date DATE
);

CREATE TABLE staff (
    staff_id      INTEGER NOT NULL PRIMARY KEY REFERENCES people (person_id),
    hired_date DATE
);
```

The following statement inserts a row into the people table:

```
INSERT INTO people
VALUES (1, 'Dave', 'Badger', 'Mr', date'1960-05-01');
```

The following statement returns an error as there is no value provided for the birth\_date column:

```
INSERT INTO people
VALUES (2, 'Simon', 'Fox', 'Mr');
```

The following statement inserts a row into the people table:

```
INSERT INTO people (person_id, given_name, family_name, title)
VALUES (2, 'Simon', 'Fox', 'Mr');
```

The following statement inserts a row into the people table and the value for the title column is populated by selecting a static value from the dual table:

```
INSERT INTO people (person_id, given_name, family_name, title)
VALUES (3, 'Dave', 'Frog', (SELECT 'Mr' FROM dual));
```

The following statement inserts multiple rows into the people table using 'SELECT' statement:

```
INSERT INTO people (person_id, given_name, family_name, title)
WITH names AS (
    SELECT 4, 'Ruth',      'Fox',      'Mrs'      FROM dual UNION ALL
    SELECT 5, 'Isabelle', 'Squirrel', 'Miss'     FROM dual UNION ALL
    SELECT 6, 'Justin',   'Frog',     'Master'   FROM dual UNION ALL
    SELECT 7, 'Lisa',     'Owl',     'Dr'       FROM dual
)
SELECT * FROM names;
```

The following statement rolls back all the previous DML operations:

```
ROLLBACK;
```

The following statement inserts multiple rows into the people table using 'SELECT' statement with a 'WHERE' condition:

```
INSERT INTO people (person_id, given_name, family_name, title)
WITH names AS (
    SELECT 4, 'Ruth',      'Fox' family_name,      'Mrs'      FROM dual UNION ALL
    SELECT 5, 'Isabelle', 'Squirrel' family_name, 'Miss'     FROM dual UNION ALL
    SELECT 6, 'Justin',   'Frog' family_name,     'Master'   FROM dual UNION ALL
    SELECT 7, 'Lisa',     'Owl' family_name,      'Dr'       FROM dual
)
SELECT * FROM names
WHERE family_name LIKE 'F%';
```

The following statement rolls back all the previous DML operations:

```
ROLLBACK;
```

The following statement inserts multiple rows into people, patients and staff table using 'INSERT ALL' statement:

```
INSERT ALL
/* Every one is a person */
  INTO people (person_id, given_name, family_name, title)
    VALUES (id, given_name, family_name, title)
  INTO patients (patient_id, last_admission_date)
    VALUES (id, admission_date)
  INTO staff (staff_id, hired_date)
    VALUES (id, hired_date)
WITH names AS (
  SELECT 4 id, 'Ruth' given_name, 'Fox' family_name, 'Mrs' title,
         NULL hired_date, DATE'2009-12-31' admission_date
    FROM dual UNION ALL
  SELECT 5 id, 'Isabelle' given_name, 'Squirrel' family_name, 'Miss' title ,
         NULL hired_date, DATE'2014-01-01' admission_date
    FROM dual UNION ALL
  SELECT 6 id, 'Justin' given_name, 'Frog' family_name, 'Master' title,
         NULL hired_date, DATE'2015-04-22' admission_date
    FROM dual UNION ALL
  SELECT 7 id, 'Lisa' given_name, 'Owl' family_name, 'Dr' title,
         DATE'2015-01-01' hired_date, NULL admission_date
    FROM dual
)
SELECT * FROM names;
```

The following statement rolls back all the previous DML operations:

```
ROLLBACK;
```

The following statement inserts multiple rows into people, patients and staff table using 'INSERT ALL' statement with various conditions:

```
INSERT ALL
/* Everyone is a person, so insert all rows into people */
WHEN 1=1 THEN
  INTO people (person_id, given_name, family_name, title)
    VALUES (id, given_name, family_name, title)
/* Only people with an admission date are patients */
WHEN admission_date IS NOT NULL THEN
  INTO patients (patient_id, last_admission_date)
    VALUES (id, admission_date)
/* Only people with a hired date are staff */
WHEN hired_date IS NOT NULL THEN
  INTO staff (staff_id, hired_date)
    VALUES (id, hired_date)
WITH names AS (
  SELECT 4 id, 'Ruth' given_name, 'Fox' family_name, 'Mrs' title,
         NULL hired_date, DATE'2009-12-31' admission_date
    FROM dual UNION ALL
  SELECT 5 id, 'Isabelle' given_name, 'Squirrel' family_name, 'Miss' title ,
         NULL hired_date, DATE'2014-01-01' admission_date
    FROM dual UNION ALL
  SELECT 6 id, 'Justin' given_name, 'Frog' family_name, 'Master' title,
         NULL hired_date, DATE'2015-04-22' admission_date
    FROM dual UNION ALL
  SELECT 7 id, 'Lisa' given_name, 'Owl' family_name, 'Dr' title,
```

```

        DATE'2015-01-01' hired_date, NULL admission_date
      FROM dual
    )
  SELECT * FROM names;

```

## LOCK TABLE

### Purpose

Use the `LOCK TABLE` statement to lock one or more tables, table partitions, or table subpartitions in a specified mode. This lock manually overrides automatic locking and permits or denies access to a table or view by other users for the duration of your operation.

Some forms of locks can be placed on the same table at the same time. Other locks allow only one lock for a table.

A locked table remains locked until you either commit your transaction or roll it back, either entirely or to a savepoint before you locked the table.

A lock never prevents other users from querying the table. A query never places a lock on a table. Readers never block writers and writers never block readers.

### See Also:

- [Oracle Database Concepts](#) for a complete description of the interaction of lock modes
- [COMMIT](#)
- [ROLLBACK](#)
- [SAVEPOINT](#)

### Prerequisites

The table or view must be in your own schema, or you must have the `LOCK ANY TABLE` system privilege, or you must have any object privilege (except the `READ` object privilege) on the table or view.

### Syntax

*lock\_table ::=*

***partition\_extension\_clause ::=***

### Semantics

#### *schema*

Specify the schema containing the table or view. If you omit *schema*, then Oracle Database assumes the table or view is in your own schema.

#### *table | view*

Specify the name of the table or view to be locked.

If you specify *view*, then Oracle Database locks the base tables of the view.

If you specify the *partition\_extension\_clause*, then Oracle Database first acquires an implicit lock on the table. The table lock is the same as the lock you specify for the partition or subpartition, with two exceptions:

- If you specify a **SHARE** lock for the subpartition, then the database acquires an implicit **ROW SHARE** lock on the table.
- If you specify an **EXCLUSIVE** lock for the subpartition, then the database acquires an implicit **ROW EXCLUSIVE** lock on the table.

If you specify **PARTITION** and *table* is composite-partitioned, then the database acquires locks on all the subpartitions of the partition.

### Restrictions on Locking Tables

The following restrictions apply to locking tables:

- If *view* is part of a hierarchy, then it must be the root of the hierarchy.
- You can acquire locks on only the existing partitions in an automatic list-partitioned table. That is, when you specify the following statement, the partition key value must correspond to a partition that already exists in the table; it cannot correspond to a partition that might be created on-demand at a later time:

```
LOCK TABLE ... PARTITION FOR (partition_key_value) ...
```

#### *dblink*

Specify a database link to a remote Oracle Database where the table or view is located. You can lock tables and views on a remote database only if you are using

Oracle distributed functionality. All tables locked by a `LOCK TABLE` statement must be on the same database.

If you omit `dblink`, then Oracle Database assumes the table or view is on the local database.

 **See Also:**

"[References to Objects in Remote Databases](#)" for information on specifying database links

### ***lockmode* Clause**

Specify one of the following modes:

#### **ROW SHARE**

`ROW SHARE` permits concurrent access to the locked table but prohibits users from locking the entire table for exclusive access. `ROW SHARE` is synonymous with `SHARE UPDATE`, which is included for compatibility with earlier versions of Oracle Database.

#### **ROW EXCLUSIVE**

`ROW EXCLUSIVE` is the same as `ROW SHARE`, but it also prohibits locking in `SHARE` mode. `ROW EXCLUSIVE` locks are automatically obtained when updating, inserting, or deleting.

#### **SHARE UPDATE**

See [ROW SHARE](#).

#### **SHARE**

`SHARE` permits concurrent queries but prohibits updates to the locked table.

#### **SHARE ROW EXCLUSIVE**

`SHARE ROW EXCLUSIVE` is used to look at a whole table and to allow others to look at rows in the table but to prohibit others from locking the table in `SHARE` mode or from updating rows.

#### **EXCLUSIVE**

`EXCLUSIVE` permits queries on the locked table but prohibits any other activity on it.

#### **NOWAIT**

Specify `NOWAIT` if you want the database to return control to you immediately if the specified table, partition, or table subpartition is already locked by another user. In this case, the database returns a message indicating that the table, partition, or subpartition is already locked by another user.

#### **WAIT**

Use the `WAIT` clause to indicate that the `LOCK TABLE` statement should wait up to the specified number of seconds to acquire a DML lock. There is no limit on the value of `integer`.

If you specify neither `NOWAIT` nor `WAIT`, then the database waits indefinitely until the table is available, locks it, and returns control to you. When the database is executing DDL statements concurrently with DML statements, a timeout or deadlock can sometimes result. The database detects such timeouts and deadlocks and returns an error.

 **See Also:**

*Oracle Database Administrator's Guide* for more information about locking tables

## Examples

### Locking a Table: Example

The following statement locks the `employees` table in exclusive mode but does not wait if another user already has locked the table:

```
LOCK TABLE employees
    IN EXCLUSIVE MODE
    NOWAIT;
```

The following statement locks the remote `employees` table that is accessible through the database link `remote`:

```
LOCK TABLE employees@remote
    IN SHARE MODE;
```

# SQL Statements: MERGE to UPDATE

This chapter contains the following SQL statements:

- MERGE
- NOAUDIT (Traditional Auditing)
- NOAUDIT (Unified Auditing)
- PURGE
- RENAME
- REVOKE
- ROLLBACK
- SAVEPOINT
- SELECT
- SET CONSTRAINT[S]
- SET ROLE
- SET TRANSACTION
- TRUNCATE CLUSTER
- TRUNCATE TABLE
- UPDATE

## MERGE

### Purpose

Use the `MERGE` statement to select rows from one or more sources for update or insertion into a table or view. You can specify conditions to determine whether to update or insert into the target table or view.

This statement is a convenient way to combine multiple operations. It lets you avoid multiple `INSERT`, `UPDATE`, and `DELETE` DML statements.

`MERGE` is a deterministic statement. You cannot update the same row of the target table multiple times in the same `MERGE` statement.

**Note:**

In previous releases of Oracle Database, when you created an Oracle Virtual Private Database policy on an application that included the MERGE INTO statement, the MERGE INTO statement would be prevented with an ORA-28132: Merge into syntax does not support security policies error, due to the presence of the Virtual Private Database policy. Beginning with Oracle Database 11g Release 2 (11.2.0.2), you can create policies on applications that include MERGE INTO operations. To do so, in the DBMS\_RLS.ADD\_POLICY statement\_types parameter, include the INSERT, UPDATE, and DELETE statements, or just omit the statement\_types parameter altogether. Refer to *Oracle Database Security Guide* for more information on enforcing policies on specific SQL statement types.

**Prerequisites**

You must have the INSERT and UPDATE object privileges on the target table and the SELECT object privilege on the source objects. To specify the DELETE clause of the *merge\_update\_clause*, you must also have the DELETE object privilege on the target table or view.

**Syntax*****merge ::=*****Note:**

You must specify at least one of the clauses *merge\_update\_clause* or *merge\_insert\_clause*.

(*merge\_update\_clause ::=*, *merge\_insert\_clause ::=*, *error\_logging\_clause ::=*

*values\_clause ::=*

*merge\_update\_clause ::=*

*merge\_insert\_clause ::=*

*where\_clause ::=*

*error\_logging\_clause ::=*

## Semantics

### INTO Clause

Use the `INTO` clause to specify the target table or view you are updating or inserting into. In order to merge data into a view, the view must be updatable. Refer to "[Notes on Updatable Views](#)" for more information.

### Restriction on Target Views

You cannot specify a target view on which an `INSTEAD OF` trigger has been defined.

### USING Clause

Use the `USING` clause to specify the source you are updating or inserting from.

#### *values\_clause*

For semantics of the `values_clause` please see the `values_clause` of the `SELECT` statement [values\\_clause](#).

### ON Clause

Use the `ON` clause to specify the condition upon which the `MERGE` operation either updates or inserts. For each row in the target table for which the search condition is true, Oracle Database updates the row with corresponding data from the source . If the condition is not true for any rows, then the database inserts into the target table based on the corresponding source row.

#### *merge\_update\_clause*

The `merge_update_clause` specifies the new column values of the target table or view. Oracle performs this update if the condition of the `ON` clause is true. If the update clause is executed, then all update triggers defined on the target table are activated.

Specify the `where_clause` if you want the database to execute the update operation only if the specified condition is true. The condition can refer to either the data source or the target table. If the condition is not true, then the database skips the update operation when merging the row into the table.

Specify the `DELETE where_clause` to clean up data in a table while populating or updating it. The only rows affected by this clause are those rows in the destination table that are updated by the merge operation. The `DELETE WHERE` condition evaluates the updated value, not the original value that was evaluated by the `UPDATE SET ... WHERE` condition. If a row of the destination table meets the `DELETE` condition but is not included in the join defined by the `ON` clause, then it is not deleted. Any delete triggers defined on the target table will be activated for each row deletion.

You can specify this clause by itself or with the `merge_insert_clause`. If you specify both, then they can be in either order.

#### Restrictions on the `merge_update_clause`

This clause is subject to the following restrictions:

- You cannot update a column that is referenced in the `ON condition` clause.
- You cannot specify `DEFAULT` when updating a view.

### ***merge\_insert\_clause***

The *merge\_insert\_clause* specifies values to insert into the column of the target table if the condition of the *ON* clause is false. If the insert clause is executed, then all insert triggers defined on the target table are activated. If you omit the column list after the `INSERT` keyword, then the number of columns in the target table must match the number of values in the `VALUES` clause.

To insert all of the source rows into the table, you can use a **constant filter predicate** in the *ON* clause condition. An example of a constant filter predicate is `ON (0=1)`. Oracle Database recognizes such a predicate and makes an unconditional insert of all source rows into the table. This approach is different from omitting the *merge\_update\_clause*. In that case, the database still must perform a join. With constant filter predicate, no join is performed.

Specify the *where\_clause* if you want Oracle Database to execute the insert operation only if the specified condition is true. The condition can refer only to the data source columns. Oracle Database skips the insert operation for all rows for which the condition is not true.

You can specify the *merge\_insert\_clause* by itself or with the *merge\_update\_clause*. If you specify both, then they can be in either order.

#### **Restriction on the *merge\_insert\_clause***

You cannot specify `DEFAULT` when inserting into a view.

#### ***error\_logging\_clause***

The *error\_logging\_clause* has the same behavior in a `MERGE` statement as in an `INSERT` statement. Refer to the `INSERT` statement *error\_logging\_clause* for more information.

#### **See Also:**

["Inserting Into a Table with Error Logging: Example"](#)

### **Examples**

#### **Merging into a Table: Example**

The following example uses the `bonuses` table in the sample schema `oe` with a default bonus of 100. It then inserts into the `bonuses` table all employees who made sales, based on the `sales_rep_id` column of the `oe.orders` table. Finally, the human resources manager decides that employees with a salary of \$8000 or less should receive a bonus. Those who have not made sales get a bonus of 1% of their salary. Those who already made sales get an increase in their bonus equal to 1% of their salary. The `MERGE` statement implements these changes in one step:

```
CREATE TABLE bonuses (employee_id NUMBER, bonus NUMBER DEFAULT 100);
INSERT INTO bonuses(employee_id)
  (SELECT e.employee_id FROM hr.employees e, oe.orders o
   WHERE e.employee_id = o.sales_rep_id
   GROUP BY e.employee_id);

SELECT * FROM bonuses ORDER BY employee_id;

EMPLOYEE_ID      BONUS
```

```

160      100  

161      100  

163      100  

MERGE INTO bonuses D
  USING (SELECT employee_id, salary, department_id FROM hr.employees
 WHERE department_id = 80) S
 ON (D.employee_id = S.employee_id)
 WHEN MATCHED THEN UPDATE SET D.bonus = D.bonus + S.salary*.01
      DELETE WHERE (S.salary > 8000)
 WHEN NOT MATCHED THEN INSERT (D.employee_id, D.bonus)
      VALUES (S.employee_id, S.salary*.01)
      WHERE (S.salary <= 8000);
  

SELECT * FROM bonuses ORDER BY employee_id;

179      62

```

### Conditional Insert and Update: Example

The following example conditionally inserts and updates table data by using the `MERGE` statement.

The following statements create two tables named `people_source` and `people_target` and populate them with names:

```

CREATE TABLE people_source (
  person_id  INTEGER NOT NULL PRIMARY KEY,
  first_name VARCHAR2(20) NOT NULL,
  last_name  VARCHAR2(20) NOT NULL,
  title      VARCHAR2(10) NOT NULL
);

CREATE TABLE people_target (
  person_id  INTEGER NOT NULL PRIMARY KEY,
  first_name VARCHAR2(20) NOT NULL,
  last_name  VARCHAR2(20) NOT NULL,

```

```

        title      VARCHAR2(10) NOT NULL
);

INSERT INTO people_target VALUES (1, 'John', 'Smith', 'Mr');
INSERT INTO people_target VALUES (2, 'alice', 'jones', 'Mrs');
INSERT INTO people_source VALUES (2, 'Alice', 'Jones', 'Mrs.');
INSERT INTO people_source VALUES (3, 'Jane', 'Doe', 'Miss');
INSERT INTO people_source VALUES (4, 'Dave', 'Brown', 'Mr');

COMMIT;

```

The following statement compares the contents of `people_target` and `people_source` by using the `person_id` column. The values in the `people_target` table are updated when there is a match in the `people_source` table:

```

MERGE INTO people_target pt
USING people_source ps
ON      (pt.person_id = ps.person_id)
WHEN MATCHED THEN UPDATE
    SET pt.first_name = ps.first_name,
        pt.last_name = ps.last_name,
        pt.title = ps.title;

```

The following statements display the contents of the `people_target` table and perform a rollback:

```

SELECT * FROM people_target;

PERSON_ID FIRST_NAME          LAST_NAME          TITLE
-----  -----
1 John           Smith          Mr
2 Alice          Jones          Mrs.

ROLLBACK;

```

This statement compares the contents of the `people_target` and `people_source` tables by using the `person_id` column. The values in the `people_target` table are updated only when there is no match in the `people_source` table:

```

MERGE INTO people_target pt
USING people_source ps
ON      (pt.person_id = ps.person_id)
WHEN NOT MATCHED THEN INSERT
    (pt.person_id, pt.first_name, pt.last_name, pt.title)
    VALUES (ps.person_id, ps.first_name, ps.last_name, ps.title);

```

The following statements display the contents of the `people_target` table and perform a rollback:

```

SELECT * FROM people_target;

PERSON_ID FIRST_NAME          LAST_NAME          TITLE
-----  -----

```

```
-----  
1 John      Smith      Mr  
2 alice     jones      Mrs  
3 Jane      Doe        Miss  
4 Dave      Brown      Mr  
  
ROLLBACK;
```

The following statement compares the contents of the `people_target` and `people_source` tables by using the `person_id` column and conditionally inserts and updates data in the `people_target` table. For each matching row in the `people_source` table, the values in the `people_target` table are updated by using the values from the `people_source` table. Any unmatched rows from the `people_source` table are added to the `people_target` table:

```
MERGE INTO people_target pt
USING people_source ps
ON      (pt.person_id = ps.person_id)
WHEN MATCHED THEN UPDATE
    SET pt.first_name = ps.first_name,
        pt.last_name = ps.last_name,
        pt.title = ps.title
WHEN NOT MATCHED THEN INSERT
    (pt.person_id, pt.first_name, pt.last_name, pt.title)
VALUES (ps.person_id, ps.first_name, ps.last_name, ps.title);
```

The following statements display the contents of the `people_target` table and perform a rollback:

```
SELECT * FROM people_target;  
  
PERSON_ID FIRST_NAME      LAST_NAME      TITLE
-----  
1 John      Smith      Mr  
2 Alice     Jones      Mrs.  
3 Jane      Doe        Miss  
4 Dave      Brown      Mr  
  
ROLLBACK;
```

The following statement compares the `people_target` and `people_source` tables by using the `person_id` column. When the `person_id` matches, the corresponding rows in the `people_target` table are updated by using values from the `people_source` table. The `DELETE` clause removes all the values in `people_target` where title is 'Mrs.'. When the `person_id` does not match, the rows from the `people_source` table are added to the `people_target` table. The `WHERE` clause ensures that only values that have title as 'Mr' are added to the `people_target` table:

```
MERGE INTO people_target pt
USING people_source ps
ON      (pt.person_id = ps.person_id)
WHEN MATCHED THEN UPDATE
```

```

SET pt.first_name = ps.first_name,
    pt.last_name = ps.last_name,
    pt.title = ps.title
DELETE where pt.title = 'Mrs.'
WHEN NOT MATCHED THEN INSERT
(pt.person_id, pt.first_name, pt.last_name, pt.title)
VALUES (ps.person_id, ps.first_name, ps.last_name, ps.title)
WHERE ps.title = 'Mr';

```

The following statements display the contents of the `people_target` table and perform a rollback:

```

SELECT * FROM people_target;

PERSON_ID FIRST_NAME           LAST_NAME          TITLE
-----  -----
1      John        Smith            Mr
4      Dave        Brown            Mr

ROLLBACK;

```

### Dealing with Inputs from an Application

Usually applications have to check for the existence of a row first in order to decide whether to `INSERT` a new row, or `UPDATE` an already existing one. The `MERGE` statement eliminates the need for such a check by allowing the use of bind variables inside the `USING` statement as a source.

The following statements demonstrate the use of bind variables to insert a new row into the `people_target` table:

```

var person_id  NUMBER;
var first_name VARCHAR2(20);
var last_name  VARCHAR2(20);
var title      VARCHAR2(10);

exec :person_id := 3;
exec :first_name := 'Gerald';
exec :last_name := 'Walker';
exec :title := 'Mr';

MERGE INTO people_target pt
  USING (SELECT :person_id AS person_id,
               :first_name AS first_name,
               :last_name AS last_name,
               :title      AS title FROM DUAL) ps
    ON (pt.person_id = ps.person_id)
WHEN MATCHED THEN UPDATE
  SET pt.first_name = ps.first_name,
      pt.last_name = ps.last_name,
      pt.title = ps.title
WHEN NOT MATCHED THEN INSERT

```

```
(pt.person_id, pt.first_name, pt.last_name, pt.title)
VALUES (ps.person_id, ps.first_name, ps.last_name, ps.title);
```

The following statements display the contents of the `people_target` table and perform a rollback:

```
SELECT * FROM people_target;
```

| PERSON_ID | FIRST_NAME | LAST_NAME | TITLE |
|-----------|------------|-----------|-------|
| 1         | John       | Smith     | Mr    |
| 2         | alice      | jones     | Mrs   |
| 3         | Gerald     | Walker    | Mr    |

```
ROLLBACK;
```

The following statements demonstrate the use of bind variables to update an already existing row in the `people_target`. Note that the `MERGE` statement is identical to the one just used to insert a new row:

```
var person_id NUMBER;
var first_name VARCHAR2(20);
var last_name VARCHAR2(20);
var title      VARCHAR2(10);

exec :person_id := 2;
exec :first_name := 'Alice';
exec :last_name := 'Jones';
exec :title := 'Mrs';

MERGE INTO people_target pt
  USING (SELECT :person_id AS person_id,
               :first_name AS first_name,
               :last_name  AS last_name,
               :title      AS title FROM DUAL) ps
    ON (pt.person_id = ps.person_id)
  WHEN MATCHED THEN UPDATE
    SET pt.first_name = ps.first_name,
        pt.last_name = ps.last_name,
        pt.title = ps.title
  WHEN NOT MATCHED THEN INSERT
    (pt.person_id, pt.first_name, pt.last_name, pt.title)
    VALUES (ps.person_id, ps.first_name, ps.last_name, ps.title);
```

The following statements display the contents of the `people_target` table and perform a rollback:

```
SELECT * FROM people_target;
```

| PERSON_ID | FIRST_NAME | LAST_NAME | TITLE |
|-----------|------------|-----------|-------|
| 1         | John       | Smith     | Mr    |
| 2         | Alice      | Jones     | Mrs   |

```
ROLLBACK;
```

## NOAUDIT (Traditional Auditing)

### See Also:

Traditional auditing is unsupported in 23c. Databases migrated from earlier versions may still have traditional auditing policies configured. Those policies should be migrated to unified auditing. When migrated, the traditional audit policies may be removed with the NOAUDIT statement.

This section describes the NOAUDIT statement for **traditional auditing**, which is the same auditing functionality used in releases earlier than Oracle Database 12c.

Beginning with Oracle Database 12c, Oracle introduces **unified auditing**, which provides a full set of enhanced auditing features. For backward compatibility, traditional auditing is still supported. However, Oracle recommends that you plan the migration of your existing audit settings to the new unified audit policy syntax. For new audit requirements, Oracle recommends that you use the new unified auditing. Traditional auditing may be unsupported in a future major release.

### See Also:

[NOAUDIT \(Unified Auditing\)](#) for a description of the NOAUDIT statement for unified auditing

### Purpose

Use the NOAUDIT statement to stop auditing operations previously enabled by the AUDIT statement.

The NOAUDIT statement must have the same syntax as the previous AUDIT statement. Further, it reverses the effects only of that particular statement. For example, suppose one AUDIT statement A enables auditing for a specific user. A second statement B enables auditing for all users. A NOAUDIT statement C to disable auditing for all users reverses statement B. However, statement C leaves statement A in effect and continues to audit the user that statement A specified.

### See Also:

[AUDIT \(Traditional Auditing\)](#)

### Prerequisites

To stop auditing of SQL statements, you must have the AUDIT SYSTEM system privilege.

To stop auditing of schema objects, you must be the owner of the object on which you stop auditing or you must have the AUDIT ANY system privilege. In addition, if the object you chose for auditing is a directory, then even if you created it, you must have the AUDIT ANY system privilege.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root and you must have the commonly granted AUDIT SYSTEM privilege in order to stop auditing for the issuances of a SQL statement, or the commonly granted AUDIT ANY privilege in order to stop auditing for the operations on a schema object. To specify CONTAINER = CURRENT, the current container must be a pluggable database (PDB) and you must have the locally granted AUDIT SYSTEM privilege in order to stop auditing the issuances of a SQL statement, or the locally granted AUDIT ANY privilege in order to stop auditing operations on a schema object.

### Syntax

*noaudit::=*

(*audit\_operation\_clause::=*, *auditing\_by\_clause::=*, *audit\_schema\_object\_clause::=*)

*audit\_operation\_clause::=*

***auditing\_by\_clause ::=***

***audit\_schema\_object\_clause ::=***

***auditing\_on\_clause ::=***

## Semantics

### ***audit\_operation\_clause***

Use the *audit\_operation\_clause* to stop auditing of a particular SQL statement.

#### ***statement\_option***

For *sql\_statement\_shortcut*, specify the shortcut for the SQL statements for which auditing is to be stopped. Refer to [#unique\\_888/unique\\_888\\_Connect\\_42\\_BABEFEAC](#) and [#unique\\_888/unique\\_888\\_Connect\\_42\\_G2274817](#) for a list of the SQL statement shortcuts and the SQL statements they audit.

#### **ALL**

Specify ALL to stop auditing of all statement options currently being audited because of an earlier AUDIT ALL ... statement. You cannot use this clause to reverse an earlier AUDIT ALL STATEMENTS ... statement.

#### **ALL STATEMENTS**

Specify ALL STATEMENTS to reverse an earlier AUDIT ALL STATEMENTS ... statement. You cannot use this clause to reverse an earlier AUDIT ALL ... statement.

### **system\_privilege**

For *system\_privilege*, specify the system privilege for which auditing is to be stopped. Refer to [Table 18-1](#) for a list of the system privileges and the statements they authorize.

### **ALL PRIVILEGES**

Specify ALL PRIVILEGES to stop auditing of all system privileges currently being audited.

### **auditing\_by\_clause**

Use the *auditing\_by\_clause* to stop auditing only for SQL statements issued by the specified users in their subsequent sessions. If you omit this clause, then Oracle Database stops auditing for all users' statements, except for the situation described for WHENEVER SUCCESSFUL.

### **audit\_schema\_object\_clause**

Use the *audit\_schema\_object\_clause* to stop auditing of a particular database object.

### **sql\_operation**

For *sql\_operation*, specify the type of operation for which auditing is to be stopped on the object specified in the ON clause. Refer to [#unique\\_888/unique\\_888\\_Connect\\_42\\_BABCFIEA](#) for a list of these options.

### **ALL**

Specify ALL as a shortcut equivalent to specifying all SQL operations applicable for the type of object.

### **auditing\_on\_clause**

The *auditing\_on\_clause* lets you specify the particular schema object for which auditing is to be stopped.

- For object, specify the object name of a table, view, sequence, stored procedure, function, or package, materialized view, or library. If you do not qualify *object* with *schema*, then Oracle Database assumes the object is in your own schema. Refer to [AUDIT \(Traditional Auditing\)](#) for information on auditing specific schema objects.
- The DIRECTORY clause lets you specify the name of the directory on which auditing is to be stopped.
- The SQL TRANSLATION PROFILE clause lets you specify the SQL translation profile on which auditing is to be stopped.
- Specify DEFAULT to remove the specified object options as default object options for subsequently created objects.

### **NETWORK**

Use this clause to discontinue auditing of database link usage and logins.

### **DIRECT\_PATH LOAD**

Use this clause to discontinue auditing of SQL\*Loader direct path loads.

### **WHENEVER [NOT] SUCCESSFUL**

Specify WHENEVER SUCCESSFUL to stop auditing only for SQL statements and operations on schema objects that complete successfully.

Specify WHENEVER NOT SUCCESSFUL to stop auditing only for SQL statements and operations that result in Oracle Database errors.

If you omit this clause, then the database stops auditing for all statements or operations, regardless of success or failure.

### CONTAINER Clause

Use the CONTAINER clause to specify the scope of the NOAUDIT command.

- Specify CONTAINER = CURRENT to stop auditing in the PDB to which you are connected. If you specify the *auditing\_by\_clause*, then *user* must be a common user or local user in the current PDB. If you specify the *auditing\_on\_clause*, then the objects must be local objects in the current PDB.
- Specify CONTAINER = ALL to stop auditing across the entire CDB. If you specify the *auditing\_by\_clause*, then *user* must be a common user. If you do not specify the *auditing\_by\_clause*, then auditing is stopped for all common users and all local users in each PDB. If you specify the *auditing\_on\_clause*, then the objects must be common objects.

If you omit this clause, then CONTAINER = CURRENT is the default.

### Examples

#### Stop Auditing of SQL Statements Related to Roles: Example

If you have chosen auditing for every SQL statement that creates or drops a role, then you can stop auditing of such statements by issuing the following statement:

```
NOAUDIT ROLE;
```

#### Stop Auditing of Updates or Queries on Objects Owned by a Particular User: Example

If you have chosen auditing for any statement that queries or updates any table issued by the users *hr* and *oe*, then you can stop auditing for queries by *hr* by issuing the following statement:

```
NOAUDIT SELECT TABLE BY hr;
```

The preceding statement stops auditing only queries by *hr*, so the database continues to audit queries and updates by *oe* as well as updates by *hr*.

#### Stop Auditing of Statements Authorized by a Particular Object Privilege: Example

To stop auditing on all statements that are authorized by DELETE ANY TABLE system privilege, issue the following statement:

```
NOAUDIT DELETE ANY TABLE;
```

#### Stop Auditing of Queries on a Particular Object: Example

If you have chosen auditing for every SQL statement that queries the *employees* table in the schema *hr*, then you can stop auditing for such queries by issuing the following statement:

```
NOAUDIT SELECT  
    ON hr.employees;
```

## Stop Auditing of Queries that Complete Successfully: Example

You can stop auditing for queries that complete successfully by issuing the following statement:

```
NOAUDIT SELECT
  ON hr.employees
  WHENEVER SUCCESSFUL;
```

This statement stops auditing only for successful queries. Oracle Database continues to audit queries resulting in Oracle Database errors.

# NOAUDIT (Unified Auditing)

This section describes the NOAUDIT statement for **unified auditing**. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to *Oracle Database Security Guide* for more information on unified auditing.

### Purpose

Use the NOAUDIT statement to:

- Disable a unified audit policy for all users or for specified users
- Exclude the values of context attributes from audit records

Changes made to the audit policy become effective immediately in the current session and in all active sessions without re-login.

#### See Also:

- [AUDIT \(Unified Auditing\)](#)
- [CREATE AUDIT POLICY \(Unified Auditing\)](#)
- [ALTER AUDIT POLICY \(Unified Auditing\)](#)
- [DROP AUDIT POLICY \(Unified Auditing\)](#)

### Prerequisites

You must have the AUDIT SYSTEM system privilege or the AUDIT\_ADMIN role.

If you are connected to a multitenant container database (CDB), then to disable a common unified audit policy, the current container must be the root and you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT\_ADMIN common role. To disable a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT\_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT\_ADMIN local role in the container.

To specify the NOAUDIT CONTEXT ... statement when connected to a CDB, you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT\_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT\_ADMIN local role in the current session's container.

## Syntax

*unified\_noaudit ::=*

*by\_users\_with\_roles ::=*

## Semantics

*policy*

Specify the name of the unified audit policy you want to disable.

You can find descriptions of all unified audit policies by querying the AUDIT\_UNIFIED\_POLICIES view and descriptions of all *enabled* unified audit policies by querying the AUDIT\_UNIFIED\_ENABLED\_POLICIES view.

### See Also:

*Oracle Database Reference* for more information on the AUDIT\_UNIFIED\_POLICIES and AUDIT\_UNIFIED\_ENABLED\_POLICIES views

## CONTEXT Clause

Specify the CONTEXT clause to exclude the values of context attributes in audit records.

- For *namespace*, specify the context namespace.
- For *attribute*, specify one or more context attributes whose values you want to exclude from audit records.

If you specify the CONTEXT clause when the current container is the root of a CDB, then the values of context attributes will be included in audit records only for events executed in the root. If you specify the optional BY clause, then *user* must be a common user.

If you specify the CONTEXT clause when the current container is a pluggable database (PDB), then the values of context attributes will be included in audit records only for events executed

in that PDB. If you specify the optional `BY` clause, then `user` must be a common user or a local user in that PDB.

You can find the application context attributes that are configured to be captured in the audit trail by querying the `AUDIT_UNIFIED_CONTEXTS` view.

#### See Also:

*Oracle Database Reference* for more information on the `AUDIT_UNIFIED_CONTEXTS` view

### BY

You can specify the `BY` clause for the `NOAUDIT POLICY` and `NOAUDIT CONTEXT` statements.

#### **NOAUDIT POLICY ... BY**

The behavior of the `BY` clause depends on whether `policy` is enabled for all users or specific users.

- If `policy` is enabled for all users, then you can disable `policy` for all users by omitting the `BY` clause. If you specify the `BY` clause, then the `NOAUDIT POLICY` statement will have no effect.
- If `policy` is enabled for one or more users (using the `AUDIT POLICY ... BY ...` statement), then you can:
  - Disable `policy` for one or more of those users by specifying the `BY` clause followed by the users for whom you want `policy` disabled
  - Completely disable `policy` by specifying the `BY` clause followed by all of the users for whom `policy` is enabled

If you do not specify the `BY` clause, then the `NOAUDIT POLICY` statement will have no effect.

- If `policy` is enabled for all users except specific users (using the `AUDIT POLICY ... EXCEPT ...` statement), then you can disable `policy` for all users by omitting the `BY` clause. If you specify the `BY` clause, then the `NOAUDIT POLICY` statement will have no effect.

If `policy` is a common unified audit policy, then `user` must be a common user. If `policy` is a local unified audit policy, then `user` must be a common user or a local user in the container to which you are connected.

#### **NOAUDIT CONTEXT ... BY**

The behavior of the `BY` clause depends on whether `attribute` is configured to be included in audit records for all users or specific users.

- If `attribute` is configured to be included in audit records for all users, then you can exclude `attribute` from audit records for all users by omitting the `BY` clause. If you specify the `BY` clause, then the `NOAUDIT CONTEXT` statement will have no effect.

- If *attribute* is configured to be included in audit records for specific users, then you can exclude *attribute* for one or more of those users by specifying the `BY` clause followed by the users for whom you want *attribute* excluded. If you do not specify the `BY` clause, then the `NOAUDIT CONTEXT` statement will have no effect.

#### ***by\_users\_with\_roles***

Specify this clause to disable *policy* only for users who have been directly granted the specified roles. If you subsequently grant one of the roles to an additional user, then the policy is automatically disabled for that user.

When you are connected to a CDB, if *policy* is a common unified audit policy, then *role* must be a common role. If *policy* is a local unified audit policy, then *role* must be a common role or a local role in the container to which you are connected.

#### **Examples**

The following examples disable unified audit policies that were created in the `CREATE AUDIT POLICY "Examples"` and enabled in the `AUDIT "Examples"`.

#### **Disabling a Unified Audit Policy for All Users: Example**

Assume that unified audit policy `table_pol` is enabled for all users. The following statement disables `table_pol` for all users:

```
NOAUDIT POLICY table_pol;
```

The following statement returns no rows, which verifies that `table_pol` is disabled for all users:

```
SELECT *
  FROM audit_unified_enabled_policies
 WHERE policy_name = 'TABLE_POL';
```

#### **Disabling a Unified Audit Policy for Specific Users: Example**

Assume that unified audit policy `dml_pol` is enabled for users `hr` and `sh`, as shown by the following query:

```
SELECT policy_name, enabled_option, entity_name
  FROM audit_unified_enabled_policies
 WHERE policy_name = 'DML_POL'
 ORDER BY entity_name;
```

| POLICY_NAME | ENABLED_OPTION | ENTITY_NAME |
|-------------|----------------|-------------|
| DML_POL     | BY             | HR          |
| DML_POL     | BY             | SH          |

The following statement disables `dml_pol` for user `hr`:

```
NOAUDIT POLICY dml_pol BY hr;
```

The following statement verifies that `dml_pol` is now enabled for only user `sh`:

```
SELECT policy_name, enabled_option, entity_name
  FROM audit_unified_enabled_policies
 WHERE policy_name = 'DML_POL';
```

| POLICY_NAME | ENABLED_OPTION | ENTITY_NAME |
|-------------|----------------|-------------|
|-------------|----------------|-------------|

```
-----  
DML_POL      BY      SH
```

The following statement disables `dml_pol` for user `sh`:

```
NOAUDIT POLICY dml_pol BY sh;
```

The following statement returns no rows, which verifies that `dml_pol` is disabled for all users:

```
SELECT *  
  FROM audit_unified_enabled_policies  
 WHERE policy_name = 'DML_POL';
```

### Excluding Values of Context Attributes in Audit Records: Example

The following statement instructs the database to exclude the values of namespace `USERENV` attributes `CURRENT_USER` and `DB_NAME` from all audit records for user `hr`:

```
NOAUDIT CONTEXT NAMESPACE userenv  
  ATTRIBUTES current_user, db_name  
  BY hr;
```

## PURGE

### Purpose

Use the PURGE statement to:

- Remove a table or index from your recycle bin and release all of the space associated with the object
- Remove part or all of a dropped tablespace or tablespace set from the recycle bin
- Remove the entire recycle bin

#### Note:

You cannot roll back a PURGE statement, nor can you recover an object after it is purged.

To see the contents of your recycle bin, query the `USER_RECYCLEBIN` data dictionary view. You can use the `RECYCLEBIN` synonym instead. The following two statements return the same rows:

```
SELECT * FROM RECYCLEBIN;  
SELECT * FROM USER_RECYCLEBIN;
```

## See Also:

- *Oracle Database Administrator's Guide* for information on the recycle bin and naming conventions for objects in the recycle bin
  - [FLASHBACK TABLE](#) for information on retrieving dropped tables from the recycle bin
  - *Oracle Database Reference* for information on using the `RECYCLEBIN` initialization parameter to control whether dropped tables go into the recycle bin

## Prerequisites

To purge a table, the table must reside in your own schema or you must have the `DROP ANY TABLE` system privilege, or you must have the `SYSDBA` system privilege.

To purge an index, the index must reside in your own schema or you must have the `DROP ANY INDEX` system privilege, or you must have the `SYSDBA` system privilege.

To purge a tablespace or tablespace set, you must have the `DROP TABLESPACE` system privilege, or you must have the `SYSDBA` system privilege.

To purge a tablespace set, you must also be connected to a shard catalog database as an SDB user.

To perform the PURGE DBA\_RECYLEBIN operation, you must have the SYSDBA or PURGE DBA\_RECYLEBIN system privilege.

## Syntax

*purge*::=

## Semantics

## TABLE or INDEX

Specify the name of the table or index in the recycle bin that you want to purge. You can specify either the original user-specified name or the system-generated name Oracle Database assigned to the object when it was dropped.

- If you specify the user-specified name, and if the recycle bin contains more than one object of that name, then the database purges the object that has been in the recycle bin the longest.
- System-generated recycle bin object names are unique. Therefore, if you specify the system-generated name, then the database purges that specified object.

When the database purges a table, all table partitions, LOBs and LOB partitions, indexes, and other dependent objects of that table are also purged.

#### **TABLESPACE or TABLESPACE SET**

Use this clause to purge all the objects residing in the specified tablespace or tablespace set from the recycle bin.

#### **USER *user***

Use this clause to reclaim space in a tablespace or tablespace set for a specified user. This operation is useful when a particular user is running low on disk quota for the specified tablespace or tablespace set.

#### **RECYCLEBIN**

Use this clause to purge the current user's recycle bin. Oracle Database will remove all objects from the user's recycle bin and release all space associated with objects in the recycle bin.

#### **DBA\_RECYLEBIN**

This clause is valid only if you have the SYSDBA or PURGE DBA\_RECYLEBIN system privilege. It lets you remove all objects from the system-wide recycle bin, and is equivalent to purging the recycle bin of every user. This operation is useful, for example, before backward migration.

#### **Examples**

##### **Remove a File From Your Recycle Bin: Example**

The following statement removes the table `test` from the recycle bin. If more than one version of `test` resides in the recycle bin, then Oracle Database removes the version that has been there the longest:

```
PURGE TABLE test;
```

To determine system-generated name of the table you want removed from your recycle bin, issue a `SELECT` statement on your recycle bin. Using that object name, you can remove the table by issuing a statement similar to the following statement. (The system-generated name will differ from the one shown in the example.)

```
PURGE TABLE RB$$33750$TABLE$0;
```

##### **Remove the Contents of Your Recycle Bin: Example**

To remove the entire contents of your recycle bin, issue the following statement:

```
PURGE RECYCLEBIN;
```

# RENAME

## Purpose

 **Note:**

You cannot roll back a RENAME statement.

Use the RENAME statement to rename a table, view, sequence, or private synonym.

- Oracle Database automatically transfers integrity constraints, indexes, and grants on the old object to the new object.
- Oracle Database invalidates all objects that depend on the renamed object, such as views, synonyms, and stored procedures and functions that refer to a renamed table.

 **See Also:**

[CREATE SYNONYM](#) and [DROP SYNONYM](#)

## Prerequisites

The object must be in your own schema.

## Syntax

*rename*::=

## Semantics

### *old\_name*

Specify the name of an existing table, view, sequence, or private synonym.

### *new\_name*

Specify the new name to be given to the existing object. The new name must not already be used by another schema object in the same namespace and must follow the rules for naming schema objects.

## Restrictions on Renaming Objects

Renaming objects is subject to the following restrictions:

- You cannot rename a public synonym. Instead, drop the public synonym and then re-create the public synonym with the new name.

- You cannot rename a type synonym that has any dependent tables or dependent valid user-defined object types.

 **See Also:**

["Database Object Naming Rules "](#)

## Examples

### Renaming a Database Object: Example

The following example uses a copy of the sample table `hr.departments`. To change the name of table `departments_new` to `emp_departments`, issue the following statement:

```
RENAME departments_new TO emp_departments;
```

You cannot use this statement directly to rename columns. However, you can rename a column using the `ALTER TABLE ... rename_column_clause`.

 **See Also:**

[rename\\_column\\_clause](#)

Another way to rename a column is to use the `RENAME` statement together with the `CREATE TABLE` statement with `AS subquery`. This method is useful if you are changing the structure of a table rather than only renaming a column. The following statements re-create the sample table `hr.job_history`, renaming a column from `department_id` to `dept_id`:

```
CREATE TABLE temporary
    (employee_id, start_date, end_date, job_id, dept_id)
AS SELECT
    employee_id, start_date, end_date, job_id, department_id
FROM job_history;

DROP TABLE job_history;

RENAME temporary TO job_history;
```

Any integrity constraints defined on table `job_history` will be lost in the preceding example. You will have to redefine them on the new `job_history` table using an `ALTER TABLE` statement.

# REVOKE

## Purpose

Use the `REVOKE` statement to:

- Revoke system privileges from users and roles

- Revoke roles from users, roles, and program units.
- Revoke object privileges for a particular object from users and roles
- Revoke schema privileges from users and roles

#### Note on Oracle Automatic Storage Management

A user authenticated AS SYSASM can use this statement to revoke the system privileges SYSASM, SYSOPER, and SYSDBA from a user in the Oracle ASM password file of the current node.

#### Note on Editable Objects

A REVOKE operation to revoke object privileges on an editable object actualizes the object in the current edition. See *Oracle Database Development Guide* for more information about editions and editable objects.

#### See Also:

- [GRANT](#) for information on granting system privileges and roles
- [Table 18-2](#) for a listing of the object privileges for each type of object

#### Prerequisites

To revoke a **system privilege**, you must have been granted the privilege with the ADMIN OPTION. You can revoke any privilege if you have the GRANT ANY PRIVILEGE system privilege.

To revoke a **role from a user or another role**, you must have been directly granted the role with the ADMIN OPTION or you must have created the role. You can revoke any role if you have the GRANT ANY ROLE system privilege.

To revoke a **role from a program unit**, you must be the user SYS or you must be the schema owner of the program unit.

To revoke an **object privilege**, one of the following conditions must be met:

- You must previously have granted the object privilege to the user or role.
- You must have the GRANT ANY OBJECT PRIVILEGE system privilege. In this case, you can revoke any object privilege that was granted by the object owner or on behalf of the owner by a user with the GRANT ANY OBJECT PRIVILEGE. However, you cannot revoke an object privilege that was granted by way of a WITH GRANT OPTION grant.
- You can revoke privileges on an object if you have the GRANT ANY object privilege. This does not apply to SYS objects. The ANY keyword in reference to a system privilege means that the user can perform the privilege on any objects owned by any user except for SYS.

#### See Also:

["Revoke Operations that Use GRANT ANY OBJECT PRIVILEGE: Example"](#)

The REVOKE statement can revoke only privileges and roles that were previously granted directly with a GRANT statement. You cannot use this statement to revoke:

- Privileges or roles not granted to the revokee
- Roles or object privileges granted through the operating system
- Privileges or roles granted to the revokee through roles

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root.

### Syntax

*revoke ::=*

(*revoke\_system\_privileges ::=, revoke\_object\_privileges ::=,  
revoke\_roles\_from\_programs ::=*)

*revoke\_system\_privileges ::=*

(*revoker\_clause ::=*)

*revoke\_schema\_privileges ::=*

(*revoker\_clause ::=*)

*revoke\_object\_privileges ::=*

(*on\_object\_clause ::=, revoker\_clause ::=*)

*revoker\_clause ::=*

*on\_object\_clause ::=*

*revoke\_roles\_from\_programs ::=*

*program\_unit ::=*

## Semantics

### *revoke\_system\_privileges*

Use these clauses to revoke system privileges.

### *system\_privilege*

Specify the system privilege to be revoked. Refer to [Table 18-1](#) for a list of the system privileges.

If you revoke a system privilege from a **user**, then the database removes the privilege from the user's privilege domain. Effective immediately, the user cannot exercise the privilege.

If you revoke a system privilege from a **role**, then the database removes the privilege from the privilege domain of the role. Effective immediately, users with the role enabled cannot exercise the privilege. Also, other users who have been granted the role and subsequently enable the role cannot exercise the privilege.

### See Also:

["Revoking a System Privilege from a User: Example"](#) and ["Revoking a System Privilege from a Role: Example"](#)

If you revoke a system privilege from **PUBLIC**, then the database removes the privilege from the privilege domain of each user who has been granted the privilege through **PUBLIC**. Effective immediately, such users can no longer exercise the privilege. However, the privilege is not revoked from users who have been granted the privilege directly or through roles.

Oracle Database provides a shortcut for specifying all system privileges at once: Specify `ALL PRIVILEGES` to revoke all the system privileges listed in [Table 18-1](#).

### Restriction on Revoking System Privileges

A system privilege cannot appear more than once in the list of privileges to be revoked.

#### *role*

Specify the role to be revoked.

If you revoke a role from a **user**, then the database makes the role unavailable to the user. If the role is currently enabled for the user, then the user can continue to exercise the privileges in the role's privilege domain as long as it remains enabled. However, the user cannot subsequently enable the role.

If you revoke a role from another **role**, then the database removes the privilege domain of the revoked role from the privilege domain of the revokee role. Users who have been granted and have enabled the revokee role can continue to exercise the privileges in the privilege domain of the revoked role as long as the revokee role remains enabled. However, other users who have been granted the revokee role and subsequently enable it cannot exercise the privileges in the privilege domain of the revoked role.

#### See Also:

["Revoking a Role from a User: Example"](#) and ["Revoking a Role from a Role: Example"](#)

If you revoke a role from **PUBLIC**, then the database makes the role unavailable to all users who have been granted the role through **PUBLIC**. Any user who has enabled the role can continue to exercise the privileges in its privilege domain as long as it remains enabled. However, users cannot subsequently enable the role. The role is not revoked from users who have been granted the role directly or through other roles.

### Restriction on Revoking System Roles

A system role cannot appear more than once in the list of roles to be revoked. For information on the predefined roles, refer to *Oracle Database Security Guide*.

#### *revokee\_clause*

Use the `revokee_clause` to specify the users or roles from which the system privilege, role, or object privilege is to be revoked.

#### **PUBLIC**

Specify **PUBLIC** to revoke the privileges or roles from all users.

#### *revoke\_schema\_privileges*

Use this clause to revoke schema privileges. You can revoke a schema level privilege from any user or any role if you are a user who :

- Owns the schema.
- Has a schema level privilege `WITH ADMIN OPTION`.

- Has the GRANT ANY SCHEMA PRIVILEGE system privilege. If you specify ALL PRIVILEGES , all the schema level privileges in [Table 18-3](#) are granted.

### ***revoke\_object\_privileges***

Use these clauses to revoke object privileges.

#### ***object\_privilege***

Specify the object privilege to be revoked. The object privileges, categorized by the type of object to which they apply, are described in [Table 18-2](#).

#### **Note:**

Each privilege authorizes some operation. By revoking a privilege, you prevent the revoker from performing that operation. However, multiple users may grant the same privilege to the same user, role, or PUBLIC. To remove the privilege from the grantee's privilege domain, all grantors must revoke the privilege. If even one grantor does not revoke the privilege, then the grantee can still exercise the privilege by virtue of that grant.

If you revoke an object privilege from a **user**, then the database removes the privilege from the user's privilege domain. Effective immediately, the user cannot exercise the privilege.

- If that user has granted that privilege to other users or roles, then the database also revokes the privilege from those other users or roles.
- If that user's schema contains a procedure, function, or package that contains SQL statements that exercise the privilege, then the procedure, function, or package can no longer be executed.
- If that user's schema contains a view on that object, then the database invalidates the view.
- If you revoke the REFERENCES object privilege from a user who has exercised the privilege to define referential integrity constraints, then you must specify the CASCADE CONSTRAINTS clause.

If you revoke an object privilege from a **role**, then the database removes the privilege from the privilege domain of the role. Effective immediately, users with the role enabled cannot exercise the privilege. Other users who have been granted the role cannot exercise the privilege after enabling the role.

If you revoke an object privilege from PUBLIC, then the database removes the privilege from the privilege domain of each user who has been granted the privilege through PUBLIC. Effective immediately, all such users are restricted from exercising the privilege. However, the privilege is not revoked from users who have been granted the privilege directly or through roles.

#### **ALL [PRIVILEGES]**

Specify ALL to revoke all object privileges that you have granted to the revoker. (The keyword PRIVILEGES is provided for semantic clarity and is optional.)

If no privileges have been granted on the object, then the database takes no action and does not return an error.

#### Restriction on Revoking Object Privileges

A privilege cannot appear more than once in the list of privileges to be revoked. A user, a role, or PUBLIC cannot appear more than once in the FROM clause.

#### See Also:

["Revoking an Object Privilege from a User: Example"](#), ["Revoking Object Privileges from PUBLIC: Example"](#), and ["Revoking All Object Privileges from a User: Example"](#)

#### CASCADE CONSTRAINTS

This clause is relevant only if you revoke the REFERENCES privilege or ALL [PRIVILEGES]. It drops any referential integrity constraints that the revoker has defined using the REFERENCES privilege, which might have been granted either explicitly or implicitly through a grant of ALL [PRIVILEGES].

#### See Also:

["Revoking an Object Privilege with CASCADE CONSTRAINTS: Example"](#)

#### FORCE

Specify FORCE to revoke the EXECUTE object privilege on user-defined type objects with table or type dependencies. You must use FORCE to revoke the EXECUTE object privilege on user-defined type objects with table dependencies.

If you specify FORCE, then all privileges are revoked, all dependent objects are marked INVALID, data in dependent tables becomes inaccessible, and all dependent function-based indexes are marked UNUSABLE. Regranting the necessary type privilege will revalidate the table.

#### See Also:

[Oracle Database Concepts](#) for detailed information about type dependencies and user-defined object privileges

#### *on\_object\_clause*

The *on\_object\_clause* identifies the objects on which privileges are to be revoked.

#### *object*

Specify the object on which the object privileges are to be revoked. This object can be:

- A table, view, sequence, procedure, stored function, package, or materialized view
- A synonym for a table, view, sequence, procedure, stored function, package, materialized view, or user-defined type
- A library, indextype, or user-defined operator

If you do not qualify object with *schema*, then the database assumes the object is in your own schema.

 **See Also:**

["Revoking an Object Privilege on a Sequence from a User: Example"](#)

If you revoke the READ or SELECT object privilege on the containing table or materialized view of a materialized view, whether the privilege was granted with or without the GRANT OPTION, then the database invalidates the materialized view.

If you revoke the READ or SELECT object privilege on any of the master tables of a materialized view, whether the privilege was granted with or without the GRANT OPTION, then the database invalidates both the materialized view and its containing table or materialized view.

#### ON USER

Specify the database user you want to revoke privileges from.

 **See Also:**

["Revoking an Object Privilege on a User from a User: Example"](#)

#### ON DIRECTORY

Specify the name of the directory object on which privileges are to be revoked. You cannot qualify *directory\_name* with a schema name.

 **See Also:**

[CREATE DIRECTORY](#) and "Revoking an Object Privilege on a Directory from a User: Example"

#### ON EDITION

Specify the name of the edition on which the USE object privilege is to be revoked. You cannot qualify *edition\_name* with a schema name.

#### ON MINING MODEL

Specify the name of the mining model on which privileges are to be revoked. If you do not qualify *mining\_model\_name* with *schema*, then the database assumes that the mining model is in your own schema.

#### ON JAVA SOURCE | RESOURCE

Specify the name of the Java source or resource schema object on which privileges are to be revoked. If you do not qualify *object* with *schema*, then the database assumes that the object is in your own schema.

#### ON SQL TRANSLATION PROFILE

Specify the name of the SQL translation profile on which privileges are to be revoked. If you do not qualify *profile* with *schema*, then the database assumes the profile is in your own schema.

#### *revoke\_roles\_from\_programs*

Use this clause to revoke code based access control (CBAC) roles from program units.

##### **role**

Specify the role you want to revoke.

##### **ALL**

Specify ALL to revoke all roles that are granted to the program unit.

##### **program\_unit**

Specify the program unit from which the role is to be revoked. You can specify a PL/SQL function, procedure, or package. If you do not specify *schema*, then Oracle Database assumes the function, procedure, or package is in your own schema.

#### See Also:

*Oracle Database Security Guide* for more information on revoking CBAC roles from program units

#### CONTAINER Clause

If the current container is a pluggable database (PDB):

- Specify CONTAINER = CURRENT to revoke a locally granted system privilege, object privilege, or role from a local user, common user, local role, or common role. The privilege or role is revoked from the user or role only in the current PDB. This clause does not revoke privileges granted with CONTAINER = ALL.

If the current container is the root:

- Specify CONTAINER = CURRENT to revoke a locally granted system privilege, object privilege, or role from a common user or common role. The privilege or role is revoked from the user or role only in the root. This clause does not revoke privileges granted with CONTAINER = ALL.
- Specify CONTAINER = ALL to revoke a commonly granted system privilege, object privilege on a common object, or role from a common user or common role. The privilege or role is

revoked from the user or role across the entire CDB. This clause can revoke only a privilege or role granted with CONTAINER = ALL from the specified common user or common role. This clause does not revoke privileges granted locally with CONTAINER = CURRENT. However, any locally granted privileges that depend on the commonly granted privilege being revoked are also revoked.

If you omit this clause, then CONTAINER = CURRENT is the default.

## Examples

### Revoking a System Privilege from a User: Example

The following statement revokes the DROP ANY TABLE system privilege from the users hr and oe:

```
REVOKE DROP ANY TABLE
  FROM hr, oe;
```

The users hr and oe can no longer drop tables in schemas other than their own.

### Revoking a Role from a User: Example

The following statement revokes the role dw\_manager from the user sh:

```
REVOKE dw_manager
  FROM sh;
```

The user sh can no longer enable the dw\_manager role.

### Revoking a System Privilege from a Role: Example

The following statement revokes the CREATE TABLESPACE system privilege from the dw\_manager role:

```
REVOKE CREATE TABLESPACE
  FROM dw_manager;
```

Enabling the dw\_manager role no longer allows users to create tablespaces.

### Revoking a Role from a Role: Example

To revoke the role dw\_user from the role dw\_manager, issue the following statement:

```
REVOKE dw_user
  FROM dw_manager;
```

The dw\_user role privileges are no longer granted to dw\_manager.

### Revoking an Object Privilege from a User: Example

You can grant DELETE, INSERT, READ, SELECT, and UPDATE privileges on the table orders to the user hr with the following statement:

```
GRANT ALL
  ON orders TO hr;
```

To revoke the DELETE privilege on orders from hr, issue the following statement:

```
REVOKE DELETE
  ON orders FROM hr;
```

### Revoking All Object Privileges from a User: Example

To revoke the remaining privileges on `orders` that you granted to `hr`, issue the following statement:

```
REVOKE ALL  
    ON orders FROM hr;
```

### **Revoking Object Privileges from PUBLIC: Example**

You can grant `SELECT` and `UPDATE` privileges on the view `emp_details_view` to all users by granting the privileges to the role `PUBLIC`:

```
GRANT SELECT, UPDATE  
    ON emp_details_view TO public;
```

The following statement revokes `UPDATE` privilege on `emp_details_view` from all users:

```
REVOKE UPDATE  
    ON emp_details_view FROM public;
```

Users can no longer update the `emp_details_view` view, although users can still query it. However, if you have also granted the `UPDATE` privilege on `emp_details_view` to any users, either directly or through roles, then these users retain the privilege.

### **Revoking an Object Privilege on a User from a User: Example**

You can grant the user `hr` the `INHERIT PRIVILEGES` privilege on user `sh` with the following statement:

```
GRANT INHERIT PRIVILEGES ON USER sh TO hr;
```

To revoke the `INHERIT PRIVILEGES` privilege on user `sh` from user `hr`, issue the following statement:

```
REVOKE INHERIT PRIVILEGES ON USER sh FROM hr;
```

### **Revoking an Object Privilege on a Sequence from a User: Example**

You can grant the user `oe` the `SELECT` privilege on the `departments_seq` sequence in the schema `hr` with the following statement:

```
GRANT SELECT  
    ON hr.departments_seq TO oe;
```

To revoke the `SELECT` privilege on `departments_seq` from `oe`, issue the following statement:

```
REVOKE SELECT  
    ON hr.departments_seq FROM oe;
```

However, if the user `hr` has also granted `SELECT` privilege on `departments` to `sh`, then `sh` can still use `departments` by virtue of `hr`'s grant.

### **Revoking an Object Privilege with CASCADE CONSTRAINTS: Example**

You can grant to `oe` the privileges `REFERENCES` and `UPDATE` on the `employees` table in the schema `hr` with the following statement:

```
GRANT REFERENCES, UPDATE  
    ON hr.employees TO oe;
```

The user `oe` can exercise the `REFERENCES` privilege to define a constraint in his or her own dependent table that refers to the `employees` table in the schema `hr`:

```
CREATE TABLE dependent
(dependno NUMBER,
dependname VARCHAR2(10),
employee NUMBER
CONSTRAINT in_emp REFERENCES hr.employees(employee_id) );
```

You can revoke the REFERENCES privilege on `hr.employees` from `oe` by issuing the following statement that contains the CASCADE CONSTRAINTS clause:

```
REVOKE REFERENCES
  ON hr.employees
  FROM oe
  CASCADE CONSTRAINTS;
```

Revoking `oe`'s REFERENCES privilege on `hr.employees` causes Oracle Database to drop the `in_emp` constraint, because `oe` required the privilege to define the constraint.

However, if `oe` has also been granted the REFERENCES privilege on `hr.employees` by a user other than you, then the database does not drop the constraint. `oe` still has the privilege necessary for the constraint by virtue of the other user's grant.

### Revoking an Object Privilege on a Directory from a User: Example

You can revoke the READ object privilege on directory `bfile_dir` from `hr` by issuing the following statement:

```
REVOKE READ ON DIRECTORY bfile_dir FROM hr;
```

### Revoke Operations that Use GRANT ANY OBJECT PRIVILEGE: Example

Suppose that the database administrator has granted GRANT ANY OBJECT PRIVILEGE to user `sh`. Now suppose that user `hr` grants the update privilege on the `employees` table to `oe`:

```
CONNECT hr
GRANT UPDATE ON employees TO oe WITH GRANT OPTION;
```

This grant gives user `oe` the right to pass the object privilege along to another user:

```
CONNECT oe
GRANT UPDATE ON hr.employees TO pm;
```

User `sh`, who has the GRANT ANY OBJECT PRIVILEGE, can now act on behalf of user `hr` and revoke the update privilege from user `oe`, because `oe` was granted the privilege by `hr`:

```
CONNECT sh
REVOKE UPDATE ON hr.employees FROM oe;
```

User `sh` cannot revoke the update privilege from user `pm` explicitly, because `pm` received the grant neither from the object owner (`hr`), nor from `sh`, nor from another user with GRANT ANY OBJECT PRIVILEGE, but from user `oe`. However, the preceding statement cascades, removing all privileges that depend on the one revoked. Therefore the object privilege is implicitly revoked from `pm` as well.

# ROLLBACK

## Purpose

Use the `ROLLBACK` statement to undo work done in the current transaction or to manually undo the work done by an in-doubt distributed transaction.

### Note:

Oracle recommends that you explicitly end transactions in application programs using either a `COMMIT` or `ROLLBACK` statement. If you do not explicitly commit the transaction and the program terminates abnormally, then Oracle Database rolls back the last uncommitted transaction.

### See Also:

- [Oracle Database Concepts](#) for information on transactions
- [Oracle Database Heterogeneous Connectivity User's Guide](#) for information on distributed transactions
- [SET TRANSACTION](#) for information on setting characteristics of the current transaction
- [COMMIT](#) and [SAVEPOINT](#)

## Prerequisites

To roll back your current transaction, no privileges are necessary.

To manually roll back an in-doubt distributed transaction that you originally committed, you must have the `FORCE TRANSACTION` system privilege. To manually roll back an in-doubt distributed transaction originally committed by another user, you must have the `FORCE ANY TRANSACTION` system privilege.

## Syntax

*rollback*::=

## Semantics

### WORK

The keyword `WORK` is optional and is provided for SQL standard compatibility.

### TO SAVEPOINT Clause

Specify the savepoint to which you want to roll back the current transaction. If you omit this clause, then the `ROLLBACK` statement rolls back the entire transaction.

Using `ROLLBACK` without the `TO SAVEPOINT` clause performs the following operations:

- Ends the transaction
- Undoes all changes in the current transaction
- Erases all savepoints in the transaction
- Releases any transaction locks

 **See Also:**

[SAVEPOINT](#)

Using `ROLLBACK` with the `TO SAVEPOINT` clause performs the following operations:

- Rolls back just the portion of the transaction after the savepoint. It does not end the transaction.
- Erases all savepoints created after that savepoint. The named savepoint is retained, so you can roll back to the same savepoint multiple times. Prior savepoints are also retained.
- Releases all table and row locks acquired since the savepoint. Other transactions that have requested access to rows locked after the savepoint must continue to wait until the transaction is committed or rolled back. Other transactions that have not already requested the rows can request and access the rows immediately.

### Restriction on In-doubt Transactions

You cannot manually roll back an in-doubt transaction to a savepoint.

### FORCE Clause

Specify `FORCE` to manually roll back an in-doubt distributed transaction. The transaction is identified by the *string* containing its local or global transaction ID. To find the IDs of such transactions, query the data dictionary view `DBA_2PC_PENDING`.

A `ROLLBACK` statement with a `FORCE` clause rolls back only the specified transaction. Such a statement does not affect your current transaction.

 **See Also:**

[Oracle Database Administrator's Guide](#) for more information on distributed transactions and rolling back in-doubt transactions

## Examples

### Rolling Back Transactions: Examples

The following statement rolls back your entire current transaction:

```
ROLLBACK;
```

The following statement rolls back your current transaction to savepoint `banda_sal`:

```
ROLLBACK TO SAVEPOINT banda_sal;
```

See "[Creating Savepoints: Example](#)" for a full version of the preceding example.

The following statement manually rolls back an in-doubt distributed transaction:

```
ROLLBACK WORK  
    FORCE '25.32.87';
```

# SAVEPOINT

## Purpose

Use the `SAVEPOINT` statement to create a name for a system change number (SCN), to which you can later roll back.

 **See Also:**

- [Oracle Database Concepts](#) for information on savepoints.
- [ROLLBACK](#) for information on rolling back transactions
- [SET TRANSACTION](#) for information on setting characteristics of the current transaction

## Prerequisites

None.

## Syntax

`savepoint ::=`

## Semantics

### **savepoint**

Specify the name of the savepoint to be created.

Savepoint names must be distinct within a given transaction. If you create a second savepoint with the same identifier as an earlier savepoint, then the earlier savepoint is erased. After a savepoint has been created, you can either continue processing, commit your work, roll back the entire transaction, or roll back to the savepoint.

## Examples

### **Creating Savepoints: Example**

To update the salary for Banda and Greene in the sample table hr.employees, check that the total department salary does not exceed 314,000, then reenter the salary for Greene:

```
UPDATE employees
    SET salary = 7000
    WHERE last_name = 'Banda';
SAVEPOINT banda_sal;

UPDATE employees
    SET salary = 12000
    WHERE last_name = 'Greene';
SAVEPOINT greene_sal;

SELECT SUM(salary) FROM employees;

ROLLBACK TO SAVEPOINT banda_sal;

UPDATE employees
    SET salary = 11000
    WHERE last_name = 'Greene';

COMMIT;
```

# SELECT

## Purpose

Use a **SELECT** statement or subquery to retrieve data from one or more tables, object tables, views, object views, materialized views, analytic views, or hierarchies.

If part or all of the result of a **SELECT** statement is equivalent to an existing materialized view, then Oracle Database may use the materialized view in place of one or more tables specified in the **SELECT** statement. This substitution is called **query rewrite**. It takes place only if cost optimization is enabled and the **QUERY\_REWRITE\_ENABLED** parameter is set to **TRUE**. To determine whether query rewrite has occurred, use the **EXPLAIN PLAN** statement.

### See Also:

- [SQL Queries and Subqueries](#) for general information on queries and subqueries
- [Oracle Database Data Warehousing Guide](#) for more information on materialized views, query rewrite, and analytic views and hierarchies
- If you are querying JSON data see [Query JSON Data](#)
- If you are querying XML data see [Querying XML Content Stored in Oracle XML DB](#)
- [EXPLAIN PLAN](#)

### Prerequisites

For you to select data from a table, materialized view, analytic view, or hierarchy, the object must be in your own schema or you must have the `READ` or `SELECT` privilege on the table, materialized view, analytic view, or hierarchy.

For you to select rows from the base tables of a view:

- The object must be in your own schema or you must have the `READ` or `SELECT` privilege on it, and
- Whoever owns the schema containing the object must have the `READ` or `SELECT` privilege on the base tables.

The `READ ANY TABLE` or `SELECT ANY TABLE` system privilege also allows you to select data from any table, materialized view, analytic view, or hierarchy, or the base table of any materialized view, analytic view, or hierarchy.

To specify the `FOR UPDATE` clause, the preceding prerequisites apply with the following exception: The `READ` and `READ ANY TABLE` privileges, where mentioned, do not allow you to specify the `FOR UPDATE` clause.

To issue an Oracle Flashback Query using the `flashback_query_clause`, you must have the `READ` or `SELECT` privilege on the objects in the select list. In addition, either you must have `FLASHBACK` object privilege on the objects in the select list, or you must have `FLASHBACK ANY TABLE` system privilege.

## Semantics

## ***with\_clause***

Use the *with* clause to define the following:

- PL/SQL procedures and functions (using the `plsql_declarations` clause)
  - Subquery blocks (using `subquery_factoring_clause` or `subav_factoring_clause`, or both)

## *plsql\_declarations*

The `plssql_declarations` clause lets you declare and define PL/SQL functions and procedures. You can then reference the PL/SQL functions in the query in which you specify this clause, as well as its subqueries, if any. For the purposes of name resolution, these function names have precedence over schema-level stored functions.

If the query in which you specify this clause is not a top-level `SELECT` statement, then the following rules apply to the top-level SQL statement that contains the query:

- If the top-level statement is a `SELECT` statement, then it must have either a `WITH plsql_declarations` clause or the `WITH_PLSQL` hint.
- If the top-level statement is a `DELETE`, `MERGE`, `INSERT`, or `UPDATE` statement, then it must have the `WITH_PLSQL` hint.

The `WITH_PLSQL` hint only enables you to specify the `WITH plsql_declarations` clause within the statement. It is not an optimizer hint.

#### See Also:

- [Oracle Database PL/SQL Language Reference](#) for syntax and restrictions for `function_declaration` and `procedure_declaration`.
- ["Using a PL/SQL Function in the WITH Clause: Examples"](#)

### ***subquery\_factoring\_clause***

The `subquery_factoring_clause` lets you assign a name (`query_name`) to a subquery block. You can then reference the subquery block multiple places in the query by specifying `query_name`. Oracle Database optimizes the query by treating the `query_name` as either an inline view or as a temporary table. The `query_name` is subject to the same naming conventions and restrictions as database schema objects. Refer to "[Database Object Naming Rules](#)" for information on database object names.

The column aliases following the `query_name` and the set operators separating multiple subqueries in the `AS` clause are valid and required for recursive subquery factoring. The `search_clause` and `cycle_clause` are valid only for recursive subquery factoring but are not required. See "[Recursive Subquery Factoring](#)".

You can specify this clause in any top-level `SELECT` statement and in most types of subqueries. The query name is visible to the main query and to all subsequent subqueries. For recursive subquery factoring, the query name is even visible to the subquery that defines the query name itself.

### **Recursive Subquery Factoring**

If a `subquery_factoring_clause` refers to its own `query_name` in the subquery that defines it, then the `subquery_factoring_clause` is said to be **recursive**. A recursive `subquery_factoring_clause` must contain two query blocks: the first is the **anchor member** and the second is the **recursive member**. The anchor member must appear before the recursive member, and it cannot reference `query_name`. The anchor member can be composed of one or more query blocks combined by the set operators: `UNION ALL`, `UNION`, `INTERSECT` or `MINUS`. The recursive member must follow the anchor member and must reference `query_name` exactly once. You must combine the recursive member with the anchor member using the `UNION ALL` set operator.

The number of column aliases following `WITH query_name` and the number of columns in the `SELECT` lists of the anchor and recursive query blocks must be the same.

The recursive member cannot contain any of the following elements:

- The DISTINCT keyword or a GROUP BY clause
- The *model\_clause*
- An aggregate function. However, analytic functions are permitted in the select list.
- Subqueries that refer to *query\_name*.
- Outer joins that refer to *query\_name* as the right table.

In previous releases of Oracle Database, the recursive member of a recursive WITH clause ran serially regardless of the parallelism of the entire query (also known as the top-level SELECT statement). Beginning with Oracle Database 12c Release 2 (12.2), the recursive member runs in parallel if the optimizer determines that the top-level SELECT statement can be executed in parallel.

#### ***search\_clause***

Use the SEARCH clause to specify an ordering for the rows.

- Specify BREADTH FIRST BY if you want sibling rows returned before any child rows are returned.
- Specify DEPTH FIRST BY if you want child rows returned before any siblings rows are returned.
- Sibling rows are ordered by the columns listed after the BY keyword.
- The *c\_alias* list following the SEARCH keyword must contain column names from the column alias list for *query\_name*.
- The *ordering\_column* is automatically added to the column list for the query name. The query that selects from *query\_name* can include an ORDER BY on *ordering\_column* to return the rows in the order that was specified by the SEARCH clause.

#### ***cycle\_clause***

Use the CYCLE clause to mark cycles in the recursion.

- The *c\_alias* list following the CYCLE keyword must contain column names from the column alias list for *query\_name*. Oracle Database uses these columns to detect a cycle.
- *cycle\_value* and *no\_cycle\_value* should be character strings of length 1.
- If a cycle is detected, then the cycle mark column specified by *cycle\_mark\_c\_alias* for the row causing the cycle is set to the value specified for *cycle\_value*. The recursion will then stop for this row. That is, it will not look for child rows for the offending row, but it will continue for other noncyclic rows.
- If no cycles are found, then the cycle mark column is set to the default value specified for *no\_cycle\_value*.
- The cycle mark column is automatically added to the column list for the *query\_name*.
- A row is considered to form a cycle if one of its ancestor rows has the same values for the cycle columns.

If you omit the CYCLE clause, then the recursive WITH clause returns an error if cycles are discovered. In this case, a row forms a cycle if one of its ancestor rows has the

same values for all the columns in the column alias list for *query\_name* that are referenced in the WHERE clause of the recursive member.

### Restrictions on Subquery Factoring

This clause is subject to the following restrictions:

- You can specify only one *subquery\_factoring\_clause* in a single SQL statement. Any *query\_name* defined in the *subquery\_factoring\_clause* can be used in any subsequent named query block in the *subquery\_factoring\_clause*.
- In a compound query with set operators, you cannot use the *query\_name* for any of the component queries, but you can use the *query\_name* in the FROM clause of any of the component queries.
- You cannot specify duplicate names in the column alias list for *query\_name*.
- The name used for the *ordering\_column* has to be different from the name used for *cycle\_mark\_c\_alias*.
- The *ordering\_column* and cycle mark column names cannot already be in the column alias list for *query\_name*.

#### See Also:

- [Oracle Database Concepts](#) for information about inline views
- ["Subquery Factoring: Example"](#)
- ["Recursive Subquery Factoring: Examples"](#)

### *subav\_factoring\_clause*

With the *subav\_factoring\_clause*, you can define a transitory analytic view that filters fact data prior to aggregation or adds calculated measures to a query of an analytic view. The *subav\_name* argument assigns a name to the transitory analytic view. You can then reference the transitory analytic view multiple places in the query by specifying *subav\_name*. The *subav\_name* is subject to the same naming conventions and restrictions as database schema objects. Refer to ["Database Object Naming Rules"](#) for information on database object names.

You can specify this clause in any top-level SELECT statement and in most types of subqueries. The query name is visible to the main query and to all subsequent subqueries.

The *sub\_av\_clause* argument defines a transitory analytic view.

### *sub\_av\_clause*

With the USING keyword, specify the name of an analytic view, which may be a transitory analytic view previously defined in the WITH clause or it may be a persistent analytic view. A persistent analytic view is defined in a CREATE ANALYTIC VIEW statement. If the analytic view is a persistent one, then the current user must have select access on it.

 See Also:[Analytic Views: Examples](#)***hierarchies\_clause***

The *hierarchies\_clause* specifies the hierarchies of the base analytic view that the results of the transitory analytic view are dimensioned by. With the `HIERARCHIES` keyword, specify the alias of one or more hierarchies of the base analytic view.

If you do not specify a `HIERARCHIES` clause, then the default hierarchies of the base analytic view are used.

***filter\_clauses***

You may specify a given *hier\_alias* in at most one *filter\_clause*.

***filter\_clause***

The filter clause applies the specified predicate condition to the fact table, which reduces the number of rows returned from the table before aggregation of the measure values. The predicate may contain any SQL row function or operation. The predicate may refer to any attribute of the specified hierarchy or it may refer to a measure of the analytic view if you specify the `MEASURES` keyword.

For example, the following clause restricts the aggregation of measure values to those for the first and second quarters of every year of a time hierarchy.

```
FILTER FACT (time_hier TO quarter_of_year IN (1,2))
```

If you then select from the transitory analytic view the sales for the years 2000 and 2001, the values returned are the aggregated values of the first and second quarters only.

An example of specifying a predicate for a measure in the filter clause is the following.

```
FILTER FACT (MEASURES TO sales BETWEEN 100 AND 200)
```

***attr\_dim\_alias***

The alias of an attribute dimension in the base analytic view. The `USER_ANALYTIC_VIEW_DIMENSIONS` view contains the aliases of the attribute dimensions in an analytic view.

***hier\_alias***

The alias of a hierarchy in the base analytic view. The `USER_ANALYTIC_VIEW_HIERS` view contains the aliases of the hierarchies in an analytic view.

***add\_meas\_clause***

With the `ADD MEASURES` keywords, you may add calculated measures to the transitory analytic view.

### ***calc\_meas\_clause***

Specify a name for the calculated measure and an analytic view expression that specifies values for the calculated measure. The analytic view expression can be any valid *calc\_meas\_expression* as described in [Analytic View Expressions](#). For example, the following adds a calculated measure named "share\_sales."

```
ADD MEASURES (share_sales AS (SHARE_OF(sales HIERARCHY time_hier PARENT)))
```

### ***hint***

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

#### **See Also:**

"[Hints](#)" for the syntax and description of hints

### **DISTINCT | UNIQUE**

Specify `DISTINCT` or `UNIQUE` if you want the database to return only one copy of each set of duplicate rows selected. These two keywords are synonymous. Duplicate rows are those with matching values for each expression in the select list.

#### **Restrictions on DISTINCT and UNIQUE Queries**

These types of queries are subject to the following restrictions:

- When you specify `DISTINCT` or `UNIQUE`, the total number of bytes in all select list expressions is limited to the size of a data block minus some overhead. This size is specified by the initialization parameter `DB_BLOCK_SIZE`.
- You cannot specify `DISTINCT` if the *select\_list* contains LOB columns.

### **ALL**

Specify `ALL` if you want the database to return all rows selected, including all copies of duplicates. The default is `ALL`.

### ***select\_list***

The *select\_list* lets you specify the columns you want to retrieve from the database.

#### **\* (all-column wildcard)**

Specify the all-column wildcard (asterisk) to select all columns, excluding pseudocolumns and `INVISIBLE` columns, from all tables, views, or materialized views listed in the `FROM` clause. The columns are returned in the order indicated by the `COLUMN_ID` column of the `*_TAB_COLUMNS` data dictionary view for the table, view, or materialized view.

If you are selecting from a table rather than from a view or a materialized view, then columns that have been marked as `UNUSED` by the `ALTER TABLE SET UNUSED` statement are not selected.

 See Also:

[ALTER TABLE](#), "Simple Query Examples", and "Selecting from the DUAL Table: Example"

***query\_name.\****

Specify *query\_name* followed by a period and the asterisk to select all columns from the specified subquery block. For *query\_name*, specify a subquery block name already specified in the *subquery\_factoring\_clause*. You must have specified the *subquery\_factoring\_clause* in order to specify *query\_name* in the *select\_list*. If you specify *query\_name* in the *select\_list*, then you also must specify *query\_name* in the *query\_table\_expression* (FROM clause).

***table.\* | view.\* | materialized view.\****

Specify the object name followed by a period and the asterisk to select all columns from the specified table, view, or materialized view. Oracle Database returns a set of columns in the order in which the columns were specified when the object was created. A query that selects rows from two or more tables, views, or materialized views is a join.

You can use the schema qualifier to select from a table, view, or materialized view in a schema other than your own. If you omit *schema*, then the database assumes the table, view, or materialized view is in your own schema.

 See Also:

"[Joins](#)"

***t\_alias .\****

Specify a correlation name (alias) followed by a period and the asterisk to select all columns from the object with that correlation name specified in the FROM clause of the same subquery. The object can be a table, view, materialized view, or subquery. Oracle Database returns a set of columns in the order in which the columns were specified when the object was created. A query that selects rows from two or more objects is a join.

***expr***

Specify an expression representing the information you want to select. A column name in this list can be qualified with *schema* only if the table, view, or materialized view containing the column is qualified with *schema* in the FROM clause. If you specify a member method of an object type, then you must follow the method name with parentheses even if the method takes no arguments.

The expression can also hold a scalar value that can be return values of PL/SQL functions, subqueries that return a single value per row, and SQL macros.

***c\_alias***

Specify an alias for the column expression. Oracle Database will use this alias in the column heading of the result set. The `AS` keyword is optional. The alias effectively renames the select list item for the duration of the query. The alias can be used in the `order_by_clause` but not other clauses in the query.

From 23c you can use `c_alias` in `group_by_clause`.

#### See Also:

- [Oracle Database Data Warehousing Guide](#) for information on using the `expr AS c_alias` syntax with the UNION ALL operator in queries of multiple materialized views
- ["About SQL Expressions"](#) for the syntax of `expr`

### Restrictions on the Select List

The select list is subject to the following restrictions:

- If you also specify a `group_by_clause` in this statement, then this select list can contain only the following types of expressions:
  - Constants
  - Aggregate functions and the functions `USER`, `UID`, and `SYSDATE`
  - Expressions identical to those in the `group_by_clause`. If the `group_by_clause` is in a subquery, then all columns in the select list of the subquery must match the GROUP BY columns in the subquery. If the select list and GROUP BY columns of a top-level query or of a subquery do not match, then the statement results in ORA-00979.
- From 23c you can group by `position` and `alias`.
  - Expressions involving the preceding expressions that evaluate to the same value for all rows in a group
- You can select a rowid from a join view only if the join has one and only one key-preserved table. The rowid of that table becomes the rowid of the view.

#### See Also:

[Oracle Database Administrator's Guide](#) for information on key-preserved tables

- If two or more tables have some column names in common, and if you are specifying a join in the `FROM` clause, then you must qualify column names with names of tables or table aliases.

### FROM Clause

Use the optional `FROM` clause to specify the objects from which data is selected.

You can invoke a polymorphic table function (PTF) in the query block of the `FROM` clause like other existing table functions. A PTF is a table function whose operands can have more than one type.

With Oracle Database 21c, you can write SQL table macros and use them inside the `FROM` clause, where it would be legal to call a PL/SQL function. SQL table macros are expressions, typically used in a `FROM` clause, to act as a sort of polymorphic (parameterized) views. You must define these macro functions in PL/SQL and call them from SQL for them to function as macros.

With Oracle Database 23c, you can use the `GRAPH_TABLE` operator as a table expression in the `FROM` clause.

#### See Also:

- [GRAPH\\_TABLE Operator](#)
- [PL/SQL Optimization and Tuning](#)
- [Defining SQL Macros](#)

## ONLY

The `ONLY` clause applies only to views. Specify `ONLY` if the view in the `FROM` clause is a view belonging to a hierarchy and you do not want to include rows from any of its subviews.

### *query\_table\_expression*

Use the `query_table_expression` clause to identify a subquery block, table, view, materialized view, analytic view, hierarchy, partition, or subpartition, or to specify a subquery that identifies the objects. In order to specify a subquery block, you must have specified the subquery block name (`query_name` in the `subquery_factoring_clause` or `subav_name` in the `subav_factoring_clause`).

The analytic view in the expression may be a transitory analytic view defined in the `with_clause` or a persistent analytic view.

#### See Also:

- ["Using Subqueries: Examples"](#)

## LATERAL

Specify `LATERAL` to designate `subquery` as a lateral inline view. Within a lateral inline view, you can specify tables that appear to the left of the lateral inline view in the `FROM` clause of a query. You can specify this left correlation anywhere within `subquery` (such as the `SELECT`, `FROM`, and `WHERE` clauses) and at any nesting level.

### Restrictions on LATERAL

Lateral inline views are subject to the following restrictions:

- If you specify `LATERAL`, then you cannot specify the `pivot_clause`, the `unpivot_clause`, or a pattern in the `table_reference clause`.

- If a lateral inline view contains the `query_partition_clause`, and it is the right side of a join clause, then it cannot contain a left correlation to the left table in the join clause. However, it can contain a left correlation to a table to its left in the `FROM` clause that is not the left table.
- A lateral inline view cannot contain a left correlation to the first table in a right outer join or full outer join.

 **See Also:**

["Using Lateral Inline Views: Example"](#)

### ***inline\_external\_table***

Specify this clause to inline an external table in a query. You must specify the table columns and properties for the external table that will be inlined in the query.

### ***inline\_external\_table\_properties***

This clause extends the `external_table_data_props` with the `REJECT LIMIT` and `access_driver_type` options. Use this clause to specify the properties of the external table.

In addition to supporting external data residing in operating file systems and Big Data sources and formats such as HDFS and Hive, Oracle supports external data residing in objects.

### ***modified\_external\_table***

You can use this clause to override some external table properties specified by the `CREATE TABLE` or `ALTER TABLE` statements from within a query.

You can override external table parameters at runtime.

### **Restrictions**

- You must specify the key words `EXTERNAL MODIFY` in the query. If you do not specify the keywords, you will see a Missing or invalid option error.
- You must reference an external table in the query. If you do not, you will see an error.
- You must specify at least one property in the query. One of `DEFAULT DIRECTORY`, `LOCATION`, `ACCESS PARAMETERS`, or `REJECT LIMIT`.
- If you specify more than one external table properties, they must be listed in order. First the `DEFAULT DIRECTORY` must be specified, followed by the `ACCESS PARAMETERS`, `LOCATION` and `REJECT LIMIT`. Otherwise an error will be raised.
- In the `DEFAULT DIRECTORY` clause, you must specify only one proper default directory. Otherwise a Missing `DEFAULT` keyword error will occur.
- You must enclose a filename in the `LOCATION` clause within quotes. Otherwise a Missing keyword error will occur. Note that the access driver will decide whether or not to allow a `LOCATION` clause in the query. If the clause is disallowed for a particular access driver, an error will be raised.
- For `ORACLE_LOADER` and `ORACLE_DATAPUMP` access drivers, the external file location in the `LOCATION` clause must be specified in the following format: directory: location, i.e, the

directory and location must be separated by a colon. Multiple locations in the clause must be separated by a comma. Otherwise, a Missing keyword error will occur.

- Note that LOCATION will be made optional in CREATE TABLE, and must be specified either when creating or querying the external table. Otherwise an error will be raised in the access driver.
- When populating external data using ORACLE DATAPUMP via CTAS, the external file location must be specified. This will be the only case where LOCATION clause is mandatory in CREATE TABLE.
- When overriding access parameters, a proper access parameter list must be provided in the ACCESS PARAMETERS clause, with enclosing parentheses.

Note that the syntax and allowable values for the access parameters in the *modified\_external\_table* clause are the same as for the external table DDL for each access driver. For more see *Oracle Database Utilities* for additional details regarding syntax and permissible values.

- If you specify the REJECT LIMIT, then it must either be UNLIMITED or some valid value that is within range. Otherwise a Reject limit out of range error will be raised.

#### ***modify\_external\_table\_properties***

You can specify the external table properties that you want to modify at run time using this clause. The parameters that you can modify are DEFAULT DIRECTORY, LOCATION, ACCESS PARAMETERS (BADFILE, LOGFILE, DISCARDFILE) and REJECT LIMIT.

#### **Example: Overriding External Table Parameters in a Query**

```
SELECT * FROM
sales_external EXTERNAL MODIFY (LOCATION 'sales_9.csv' REJECT LIMIT UNLIMITED);
```

#### ***flashback\_query\_clause***

Use the *flashback\_query\_clause* to retrieve data from a table, view, or materialized view based on time dimensions associated with the data.

This clause implements SQL-driven Flashback, which lets you specify the following:

- A different system change number or timestamp for each object in the select list, using the clauses VERSIONS BETWEEN { SCN | TIMESTAMP } or VERSIONS AS OF { SCN | TIMESTAMP }. You can also implement session-level Flashback using the DBMS\_FLASHBACK package.
- A valid time period for each object in the select list, using the clauses VERSIONS PERIOD FOR or AS OF PERIOD FOR. You can also implement valid-time session-level Flashback using the DBMS\_FLASHBACK\_ARCHIVE package.

A Flashback Query lets you retrieve a history of changes made to a row. You can retrieve the corresponding identifier of the transaction that made the change using the VERSIONS\_XID pseudocolumn. You can also retrieve information about the transaction that resulted in a particular row version by issuing an Oracle Flashback Transaction Query. You do this by querying the FLASHBACK\_TRANSACTION\_QUERY data dictionary view for a particular transaction ID.

#### **VERSIONS BETWEEN { SCN | TIMESTAMP }**

Specify VERSIONS BETWEEN to retrieve multiple versions of the rows returned by the query. Oracle Database returns all committed versions of the rows that existed between two SCNs or between two timestamp values. The first specified SCN or timestamp must be earlier than the second specified SCN or timestamp. The rows returned include deleted and subsequently reinserted versions of the rows.

- Specify VERSIONS BETWEEN SCN ... to retrieve the versions of the row that existed between two SCNs. Both expressions must evaluate to a number and cannot evaluate to NULL. MINVALUE and MAXVALUE resolve to the SCN of the oldest and most recent data available, respectively.
- Specify VERSIONS BETWEEN TIMESTAMP ... to retrieve the versions of the row that existed between two timestamps. Both expressions must evaluate to a timestamp value and cannot evaluate to NULL. MINVALUE and MAXVALUE resolve to the timestamp of the oldest and most recent data available, respectively.

### AS OF { SCN | TIMESTAMP }

Specify AS OF to retrieve the single version of the rows returned by the query at a particular change number (SCN) or timestamp. If you specify SCN, then *expr* must evaluate to a number. If you specify TIMESTAMP, then *expr* must evaluate to a timestamp value. In either case, *expr* cannot evaluate to NULL. Oracle Database returns rows as they existed at the specified system change number or time.

Oracle Database provides a group of version query pseudocolumns that let you retrieve additional information about the various row versions. Refer to "[Version Query Pseudocolumns](#)" for more information.

When both clauses are used together, the AS OF clause determines the SCN or moment in time from which the database issues the query. The VERSIONS clause determines the versions of the rows as seen from the AS OF point. The database returns null for a row version if the transaction started before the first BETWEEN value or ended after the AS OF point.

### VERSIONS PERIOD FOR

Specify VERSIONS PERIOD FOR to retrieve rows from *table* based on whether they are considered valid during the specified time period. In order to use this clause, *table* must support Temporal Validity.

- For *valid\_time\_column*, specify the name of the valid time dimension column for *table*.
- Use the BETWEEN clause to specify the time period during which rows are considered valid. Both expressions must evaluate to a timestamp value and cannot evaluate to NULL. MINVALUE resolves to the earliest date or timestamp in the start time column of *table*. MAXVALUE resolves to latest date or timestamp in the end time column of *table*.

### AS OF PERIOD FOR

Specify AS OF PERIOD FOR to retrieve rows from *table* based on whether they are considered valid as of the specified time. In order to use this clause, *table* must support Temporal Validity.

- For *valid\_time\_column*, specify the name of the valid time dimension column for *table*.
- Use *expr* to specify the time as of which rows are considered valid. The expression must evaluate to a timestamp value and cannot evaluate to NULL.

 See Also:

- *Oracle Database Development Guide* for more information on Temporal Validity
- CREATE TABLE *period\_definition* to learn how to configure a table to support Temporal Validity and for information about the *valid\_time\_column*, start time column, and end time column

**Note on Flashback Queries**

When performing a flashback query, Oracle Database might not use query optimizations that it would use for other types of queries, which could have a negative impact on performance. In particular, this occurs when you specify multiple flashback queries in a hierarchical query.

**Restrictions on Flashback Queries**

These queries are subject to the following restrictions:

- You cannot specify a column expression or a subquery in the expression of the AS OF clause.
- You cannot specify the AS OF clause if you have specified the *for\_update\_clause*.
- You cannot use the AS OF clause in the defining query of a materialized view.
- You cannot use the VERSIONS clause in flashback queries to temporary or external tables, or tables that are part of a cluster.
- You cannot use the VERSIONS clause in flashback queries to views. However, you can use the VERSIONS syntax in the defining query of a view.
- You cannot specify the *flashback\_query\_clause* if you have specified *query\_name* in the *query\_table\_expression*.

 See Also:

- *Oracle Database Development Guide* for more information on Oracle Flashback Query
- "[Using Flashback Queries: Example](#)"
- *Oracle Database Development Guide* and *Oracle Database PL/SQL Packages and Types Reference* for information about session-level Flashback using the DBMS\_FLASHBACK package
- *Oracle Database Administrator's Guide* and to the description of FLASHBACK\_TRANSACTION\_QUERY in the *Oracle Database Reference* for more information about transaction history

***partition\_extension\_clause***

For PARTITION or SUBPARTITION, specify the name or key value of the partition or subpartition within *table* from which you want to retrieve data.

For range- and list-partitioned data, as an alternative to this clause, you can specify a condition in the WHERE clause that restricts the retrieval to one or more partitions of *table*. Oracle Database will interpret the condition and fetch data from only those partitions. It is not possible to formulate such a WHERE condition for hash-partitioned data.

**See Also:**

"[References to Partitioned Tables and Indexes](#)" and "[Selecting from a Partition: Example](#)"

***dblink***

For *dblink*, specify the complete or partial name for a database link to a remote database where the table, view, or materialized view is located. This database need not be an Oracle Database.

**See Also:**

- "[References to Objects in Remote Databases](#)" for more information on referring to database links
- "[Distributed Queries](#)" for more information about distributed queries and "[Using Distributed Queries: Example](#)"

If you omit *dblink*, then the database assumes that the table, view, or materialized view is on the local database.

**Restrictions on Database Links**

Database links are subject to the following restrictions:

- You cannot query a user-defined type or an object REF on a remote table.
- You cannot query columns of type ANYTYPE, ANYDATA, or ANYDATASET from remote tables.

***table | view | materialized\_view | analytic\_view | hierarchy***

Specify the name of a table, view, materialized view, analytic view, or hierarchy from which data is selected.

***analytic\_view***

A persistent analytic view defined with the CREATE ANALYTIC VIEW statement or a transitory analytic view defined in a WITH clause.

 See Also:

[Analytic Views: Examples](#)

***hierarchy***

A hierarchy defined with the CREATE HIERARCHY statement.

***sample\_clause***

The *sample\_clause* lets you instruct the database to select from a random sample of data from the table, rather than from the entire table.

 See Also:

["Selecting a Sample: Examples"](#)

**BLOCK**

BLOCK instructs the database to attempt to perform random block sampling instead of random row sampling.

Block sampling is possible only during full table scans or index fast full scans. If a more efficient execution path exists, then Oracle Database does not perform block sampling. If you want to guarantee block sampling for a particular table or index, then use the FULL or INDEX\_FFS hint.

Beginning with Oracle Database 12c Release 2 (12.2.), you can specify block sampling for external tables. In earlier releases, specifying block sampling for external tables had no effect; row sampling was performed.

***sample\_percent***

For *sample\_percent*, specify the percentage of the total row or block count to be included in the sample. The value must be in the range .000001 to, but not including, 100. This percentage indicates the probability of each row, or each cluster of rows in the case of block sampling, being selected as part of the sample. It does not mean that the database will retrieve exactly *sample\_percent* of the rows of *table*.

 **WARNING:**

The use of statistically incorrect assumptions when using this feature can lead to incorrect or undesirable results.

***SEED seed\_value***

Specify this clause to instruct the database to attempt to return the same sample from one execution to the next. The *seed\_value* must be an integer between 0 and 4294967295. If you omit this clause, then the resulting sample will change from one execution to the next.

### Restrictions on *sample\_clause*

The following restrictions apply to the SAMPLE clause:

- You cannot specify the SAMPLE clause in a subquery in a DML statement.
- You can specify the SAMPLE clause in a query on a base table, a container table of a materialized view, or a view that is key preserving. You cannot specify this clause on a view that is not key preserving.

### *subquery\_restriction\_clause*

The *subquery\_restriction\_clause* lets you restrict the subquery in one of the following ways:

#### **WITH READ ONLY**

Specify WITH READ ONLY to indicate that the table or view cannot be updated.

#### **WITH CHECK OPTION**

Specify WITH CHECK OPTION to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the FROM clause but not in subquery in the WHERE clause.

#### **CONSTRAINT *constraint***

Specify the name of the CHECK OPTION constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form SYS\_Cn, where n is an integer that makes the constraint name unique within the database.

#### See Also:

"Using the WITH CHECK OPTION Clause: Example"

### *table\_collection\_expression*

The *table\_collection\_expression* lets you inform Oracle that the value of *collection\_expression* should be treated as a table for purposes of query and DML operations. The *collection\_expression* can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called **collection unnesting**.

The optional plus (+) is relevant if you are joining the TABLE collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

 Note:

In earlier releases of Oracle, when `collection_expression` was a subquery, `table_collection_expression` was expressed as THE subquery. That usage is now deprecated.

The `collection_expression` can reference columns of tables defined to its left in the `FROM` clause. This is called **left correlation**. Left correlation can occur only in `table_collection_expression`. Other subqueries cannot contain references to columns defined outside the subquery.

The optional (+) lets you specify that `table_collection_expression` should return a row with all fields set to null if the collection is null or empty. The (+) is valid only if `collection_expression` uses left correlation. The result is similar to that of an outer join.

When you use the (+) syntax in the `WHERE` clause of a subquery in an `UPDATE` or `DELETE` operation, you must specify two tables in the `FROM` clause of the subquery. Oracle Database ignores the outer join syntax unless there is a join in the subquery itself.

 See Also:

- "[Outer Joins](#)"
- "[Table Collections: Examples](#)" and "[Collection Unnesting: Examples](#)"

### t\_alias

Specify a **correlation name**, which is an alias for the table, view, materialized view, or subquery for evaluating the query. This alias is required if the select list references any object type attributes or object type methods. Correlation names are most often used in a correlated query. Other references to the table, view, or materialized view throughout the query must refer to this alias.

 See Also:

- "[Using Correlated Subqueries: Examples](#)"

### pivot\_clause

The `pivot_clause` lets you write cross-tabulation queries that rotate rows into columns, aggregating data in the process of the rotation. The output of a pivot operation typically includes more columns and fewer rows than the starting data set. The `pivot_clause` performs the following steps:

1. The `pivot_clause` computes the aggregation functions specified at the beginning of the clause. Aggregation functions must specify a `GROUP BY` clause to return

multiple values, yet the *pivot\_clause* does not contain an explicit GROUP BY clause. Instead, the *pivot\_clause* performs an implicit GROUP BY. The implicit grouping is based on all the columns not referred to in the *pivot\_clause*, along with the set of values specified in the *pivot\_in\_clause*). If you specify more than one aggregation function, then you must provide aliases for at least all but one of the aggregation functions.

2. The grouping columns and aggregated values calculated in Step 1 are configured to produce the following cross-tabular output:
  - a. All the implicit grouping columns not referred to in the *pivot\_clause*, followed by
  - b. New columns corresponding to values in the *pivot\_in\_clause*. Each aggregated value is transposed to the appropriate new column in the cross-tabulation. If you specify the XML keyword, then the result is a single new column that expresses the data as an XML string. The database generates a name for each new column. If you do not provide an alias for an aggregation function, then the database uses each pivot column value as the name for each new column to which that aggregated value is transposed. If you provide an alias for an aggregation function, then the database generates a name for each new column to which that aggregated value is transposed by concatenating the pivot column name, the underscore character (\_), and the aggregation function alias. If a generated column name exceeds the maximum length of a column name, then an ORA-00918 error is returned. To avoid this issue, specify a shorter alias for the pivot column heading, the aggregation function, or both.

The subclauses of the *pivot\_clause* have the following semantics:

#### XML

The optional XML keyword generates XML output for the query. The XML keyword permits the *pivot\_in\_clause* to contain either a subquery or the wildcard keyword ANY. Subqueries and ANY wildcards are useful when the *pivot\_in\_clause* values are not known in advance. With XML output, the values of the pivot column are evaluated at execution time. You cannot specify XML when you specify explicit pivot values using expressions in the *pivot\_in\_clause*.

When XML output is generated, the aggregate function is applied to each distinct pivot value, and the database returns a column of XMLType containing an XML string for all value and measure pairs.

#### expr

For *expr*, specify an expression that evaluates to a constant value of a pivot column. You can optionally provide an alias for each pivot column value. If there is no alias, the column heading becomes a quoted identifier.

#### subquery

A subquery is used only in conjunction with the XML keyword. When you specify a subquery, all values found by the subquery are used for pivoting. The output is not the same cross-tabular format returned by non-XML pivot queries. Instead of multiple columns specified in the *pivot\_in\_clause*, the subquery produces a single XML string column. The XML string for each row holds aggregated data corresponding to the implicit GROUP BY value of that row. The XML string for each output row includes all pivot values found by the subquery, even if there are no corresponding rows in the input data.

The subquery must return a list of unique values at the execution time of the pivot query. If the subquery does not return a unique value, then Oracle Database raises a run-time error. Use the DISTINCT keyword in the subquery if you are not sure the query will return unique values.

## ANY

The ANY keyword is used only in conjunction with the XML keyword. The ANY keyword acts as a wildcard and is similar in effect to *subquery*. The output is not the same cross-tabular format returned by non-XML pivot queries. Instead of multiple columns specified in the *pivot\_in\_clause*, the ANY keyword produces a single XML string column. The XML string for each row holds aggregated data corresponding to the implicit GROUP BY value of that row. However, in contrast to the behavior when you specify *subquery*, the ANY wildcard produces an XML string for each output row that includes only the pivot values found in the input data corresponding to that row.

### See Also:

*Oracle Database Data Warehousing Guide* for more information about PIVOT and UNPIVOT and "Using PIVOT and UNPIVOT: Examples"

## *unpivot\_clause*

The *unpivot\_clause* rotates columns into rows.

- The INCLUDE | EXCLUDE NULLS clause gives you the option of including or excluding null-valued rows. INCLUDE NULLS causes the unpivot operation to include null-valued rows; EXCLUDE NULLS eliminates null-values rows from the return set. If you omit this clause, then the unpivot operation excludes nulls.
- For *column*, specify a name for each output column that will hold measure values, such as *sales\_quantity*.
- In the *pivot\_for\_clause*, specify a name for each output column that will hold descriptor values, such as *quarter* or *product*.
- In the *unpivot\_in\_clause*, specify the input data columns whose names will become values in the output columns of the *pivot\_for\_clause*. These input data columns have names specifying a category value, such as Q1, Q2, Q3, Q4. The optional AS clause lets you map the input data column names to the specified literal values in the output columns.

The unpivot operation turns a set of value columns into one column. Therefore, the data types of all the value columns must be in the same data type group, such as numeric or character.

- If all the value columns are CHAR, then the unpivoted column is CHAR. If any value column is VARCHAR2, then the unpivoted column is VARCHAR2.
- If all the value columns are NUMBER, then the unpivoted column is NUMBER. If any value column is BINARY\_DOUBLE, then the unpivoted column is BINARY\_DOUBLE. If no value column is BINARY\_DOUBLE but any value column is BINARY\_FLOAT, then the unpivoted column is BINARY\_FLOAT.

## *containers\_clause*

The CONTAINERS clause is useful in a multitenant container database (CDB). This clause lets you query data in the specified table or view across all containers in a CDB.

- To query data in a CDB, you must be a common user connected to the CDB root, and the table or view must exist in the root and all PDBs. The query returns all rows from the table or view in the CDB root and in all open PDBs.
- To query data in an application container, you must be a common user connected to the application root, and the table or view must exist in the application root and all PDBs in the application container. The query returns all rows from the table or view in the application root and in all open PDBs in the application container.

The table or view must be in your own schema. It is not necessary to specify `schema`, but if you do then you must specify your own schema.

The query returns all rows from the table or view in the root and in all open PDBs, except PDBs that are open in `RESTRICTED` mode. If the queried table or view does not already contain a `CON_ID` column, then the query adds a `CON_ID` column to the query result, which identifies the container whose data a given row represents.

#### See Also:

- [CONTAINERS Hint](#)
- *Oracle Database Administrator's Guide* for more information on the `CONTAINERS` clause

#### `shards_clause`

Use the `shards_clause` to query Oracle supplied objects such as `V$`, `DBA/USER/ALL` views, and dictionary tables across shards. You can execute a query with the `shards_clause` only on the shard catalog database.

This feature enables easier centralized management by providing the ability to execute queries across all shards from a central shard catalog.

#### `values_clause`

You can use the `values_clause` in the `FROM` and `with_clause` of `SELECT` as a table value constructor (TVC).

Each table value constructor contains a set of row value expressions (RVE). The elements in each row expression should be homogeneous in number and their type must be compatible.

The `c_alias` or column alias is the name of the column corresponding to each expression in an RVE.

TVCs in the `FROM` clause of select statements can be used as table expressions.

#### **Example: Using the Values Constructor in the FROM Clause of SELECT**

```
SELECT *
  FROM ( VALUES (1,'SCOTT'),
                 (2,'SMITH'),
                 (3,'JOHN' )
    ) t1 (employee_id, first_name);
```

The example above creates an in-line table `t1` with two columns `employee_id` and `first_name` and three rows.

If you use the `values_clause` with the `with_clause` `with_clause::=`, you must specify the column alias. Each column alias must correspond to the column produced by the TVC. In this case, the TVC replaces the subquery.

#### Example: Using the Values Constructor in the With\_Clause of SELECT:

```
WITH X(foo, bar, baz) AS (
    VALUES (0, 1, 2), (3, 4, 5), (6, 7, 8) ) SELECT * FROM X;
```

#### Restrictions

- If multiple RVEs are specified, then each RVE should have the same cardinality. This means that each RVE must have the same number of elements.
- Each element of the RVE can be a valid SQL expression that includes a column name, scalar valued subquery, bind variable, or any other expression that evaluates to a single value.
- The type of the expression or a constant at the corresponding positions of RVE in a TVC should be implicitly convertible to the most general type following normal SQL type conversion rules. The type of expression that will be inferred will be the most general type of expression at the same position in all RVEs that constitute the TVC.
- If a scalar valued subquery is used to compute the value of an element in a RVE then the select list of scalar valued subquery can contain exactly one expression.
- If RVE is used in an `UPDATE`, or `MERGE` statement, then the keyword `DEFAULT` can be specified in a RVE for each position to indicate to the SQL engine that the default column value should be used for this column.
- The execution plan will have a new section that appears only when the TVC has RVEs consisting of constant values.
- If the types of the corresponding elements in a RVE in a TVC have different constraints, then the type of the column will be the union of all the constraints or the most relaxed constraint.
- An error will be thrown if a TVC, that consists of more than one RVE, is used in a place where a scalar valued subquery is expected.
- The parallel behavior will be similar to union all queries on `DUAL`. TVC will not impact parallel behavior.
- RVEs cannot be nested, that is, a RVE cannot contain another RVE.
- The maximum number of columns produced by the `with_clause` will be the same as the maximum number of columns in a database table.
- NDV and other statistics that are computed by the optimizer will be similar to a union of all queries on `DUAL`.
- The TVC clause will not have any restriction on number of RVEs other than the restriction imposed by available memory.
- The elimination of `UNION ALL` branches on a predicate will be similar to `UNION ALL` queries with `DUAL`.

### ***join\_clause***

Use the appropriate *join\_clause* syntax to identify tables that are part of a join from which to select data. The *inner\_cross\_join\_clause* lets you specify an inner or cross join. The *outer\_join\_clause* lets you specify an outer join. The *cross\_outer\_apply\_clause* lets you specify a variation of an ANSI CROSS JOIN or an ANSI LEFT OUTER JOIN with left correlation support.

When you join more than two row sources, you can use parentheses to override default precedence. For example, the following syntax:

```
SELECT ... FROM a JOIN (b JOIN c) ...
```

results in a join of b and c, and then a join of that result set with a.

#### **See Also:**

["Joins"](#) for more information on joins, ["Using Join Queries: Examples"](#), ["Using Self Joins: Example"](#), and ["Using Outer Joins: Examples"](#)

### ***inner\_cross\_join\_clause***

Inner joins return only those rows that satisfy the join condition.

#### **INNER**

Specify INNER to explicitly specify an inner join.

#### **JOIN**

The JOIN keyword explicitly states that a join is being performed. You can use this syntax to replace the comma-delimited table expressions used in WHERE clause joins with FROM clause join syntax.

#### **ON *condition***

Use the ON clause to specify a join condition. Doing so lets you specify join conditions separate from any search or filter conditions in the WHERE clause.

#### **USING (*column*)**

When you are specifying an equijoin of columns that have the same name in both tables, the USING *column* clause indicates the columns to be used. You can use this clause only if the join columns in both tables have the same name. Within this clause, do not qualify the column name with a table name or table alias.

#### **CROSS**

The CROSS keyword indicates that a cross join is being performed. A cross join produces the cross-product of two relations and is essentially the same as the comma-delimited Oracle Database notation.

#### **NATURAL**

The NATURAL keyword indicates that a natural join is being performed. Refer to [NATURAL](#) for the full semantics of this clause.

### ***outer\_join\_clause***

Outer joins return all rows that satisfy the join condition and also return some or all of those rows from one table for which no rows from the other satisfy the join condition. You can specify two types of outer joins: a conventional outer join using the *table\_reference* syntax on both sides of the join, or a partitioned outer join using the *query\_partition\_clause* on one side or the other. A partitioned outer join is similar to a conventional outer join except that the join takes place between the outer table and each partition of the inner table. This type of join lets you selectively make sparse data more dense along the dimensions of interest. This process is called **data densification**.

### ***query\_partition\_clause***

The *query\_partition\_clause* lets you define a **partitioned outer join**. Such a join extends the conventional outer join syntax by applying the outer join to partitions returned by the query. Oracle Database creates a partition of rows for each expression you specify in the PARTITION BY clause. The rows in each query partition have same value for the PARTITION BY expression.

The *query\_partition\_clause* can be on either side of the outer join. The result of a partitioned outer join is a UNION of the outer joins of each of the partitions in the partitioned result set and the table on the other side of the join. This type of result is useful for filling gaps in sparse data, which simplifies analytic calculations.

If you omit this clause, then the database treats the entire table expression—everything specified in *table\_reference*—as a single partition, resulting in a conventional outer join.

To use the *query\_partition\_clause* in an analytic function, use the upper branch of the syntax (without parentheses). To use this clause in a model query (in the *model\_column\_clauses*) or a partitioned outer join (in the *outer\_join\_clause*), use the lower branch of the syntax (with parentheses).

### **Restrictions on Partitioned Outer Joins**

Partitioned outer joins are subject to the following restrictions:

- You can specify the *query\_partition\_clause* on either the right or left side of the join, but not both.
- You cannot specify a FULL partitioned outer join.
- If you specify the *query\_partition\_clause* in an outer join with an ON clause, then you cannot specify a subquery in the ON condition.

#### See Also:

["Using Partitioned Outer Joins: Examples"](#)

### **NATURAL**

The NATURAL keyword indicates that a natural join is being performed. A natural join is based on all columns in the two tables that have the same name. It selects rows from the two tables that have equal values in the relevant columns. If two columns with the

same name do not have compatible data types, then an error is raised. When specifying columns that are involved in the natural join, do not qualify the column name with a table name or table alias.

On occasion, the table pairings in natural or cross joins may be ambiguous. For example, consider the following join syntax:

```
a NATURAL LEFT JOIN b LEFT JOIN c ON b.c1 = c.c1
```

This example can be interpreted in either of the following ways:

```
a NATURAL LEFT JOIN (b LEFT JOIN c ON b.c1 = c.c1)  
(a NATURAL LEFT JOIN b) LEFT JOIN c ON b.c1 = c.c1
```

To avoid this ambiguity, you can use parentheses to specify the pairings of joined tables. In the absence of such parentheses, the database uses left associativity, pairing the tables from left to right.

### Restriction on Natural Joins

You cannot specify a LOB column, columns of ANYTYPE, ANYDATA, or ANYDATASET, or a collection column as part of a natural join.

#### *outer\_join\_type*

The *outer\_join\_type* indicates the kind of outer join being performed:

- Specify `RIGHT` to indicate a right outer join.
- Specify `LEFT` to indicate a left outer join.
- Specify `FULL` to indicate a full or two-sided outer join. In addition to the inner join, rows from both tables that have not been returned in the result of the inner join will be preserved and extended with nulls.
- You can specify the optional `OUTER` keyword following `RIGHT`, `LEFT`, or `FULL` to explicitly clarify that an outer join is being performed.

#### **ON condition**

Use the `ON` clause to specify a join condition. Doing so lets you specify join conditions separate from any search or filter conditions in the `WHERE` clause.

### Restriction on the `ON condition` Clause

You cannot specify this clause with a `NATURAL` outer join.

#### **USING column**

In an outer join with the `USING` clause, the query returns a single column that coalesces the two matching columns in the join. The coalesce function is as follows:

```
COALESCE (a, b) = a if a NOT NULL, else b.
```

Therefore:

- A left outer join returns all the common column values from the left table in the `FROM` clause.
- A right outer join returns all the common column values from the right table in the `FROM` clause.
- A full outer join returns all the common column values from both joined tables.

### Restriction on the USING column Clause

The USING *column* clause is subject to the following restrictions:

- Within this clause, do not qualify the column name with a table name or table alias.
- You cannot specify a LOB column or a collection column in the USING *column* clause.
- You cannot specify this clause with a NATURAL outer join.

#### See Also:

- "[Outer Joins](#)" for additional rules and restrictions pertaining to outer joins
- *Oracle Database Data Warehousing Guide* for a complete discussion of partitioned outer joins and data densification
- "[Using Outer Joins: Examples](#)"

### *cross\_outer\_apply\_clause*

This clause allows you to perform a variation of an ANSI CROSS JOIN or an ANSI LEFT OUTER JOIN with left correlation support. You can specify a *table\_reference* or *collection\_expression* to the right of the APPLY keyword. The *table\_reference* can be a table, inline view, or TABLE collection expression. The *collection\_expression* can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. The *table\_reference* or *collection\_expression* can reference columns of tables defined in the FROM clause to the left of the APPLY keyword. This is called left correlation.

- Specify CROSS APPLY to perform a variation of an ANSI CROSS JOIN. Only rows from the table on the left side of the join that produce a result set from *table\_reference* or *collection\_expression* are returned.
- Specify OUTER APPLY to perform a variation of an ANSI LEFT OUTER JOIN. All rows from the table on the left side of the join are returned. Rows that do not produce a result set from *table\_reference* or *collection\_expression* have the NULL value in the corresponding column(s).

#### Restriction on the *cross\_outer\_apply\_clause*

The *table\_reference* cannot be a lateral inline view.

#### See Also:

- [Using CROSS APPLY and OUTER APPLY Joins: Examples](#)

### *inline\_analytic\_view*

An inline analytic view is a transitory analytic view that is specified in the FROM clause. To create an inline analytic view, use the ANALYTIC VIEW keyword and specify a

*sub\_av\_clause* that defines the analytic view. Optionally, you may specify an *inline\_av\_alias*, which is an alias for the inline analytic view. The rules for the *inline\_av\_alias* are the same as the rules for an inline view alias.

 **See Also:**

[Analytic Views: Examples](#)

#### ***where\_clause***

The `WHERE` condition lets you restrict the rows selected to those that satisfy one or more conditions. For *condition*, specify any valid SQL condition.

If you omit this clause, then the database returns all rows from the tables, views, or materialized views in the `FROM` clause.

 **Note:**

If this clause refers to a `DATE` column of a partitioned table or index, then the database performs partition pruning only if:

- You created the table or index partitions by fully specifying the year using the `TO_DATE` function with a 4-digit format mask, and
- You specify the date in the *where\_clause* of the query using the `TO_DATE` function and either a 2- or 4-digit format mask.

With Oracle Database 21c you can write macros for scalar expressions and use them inside the *where\_clause*, where it would be legal to call a PLSQL function.

You must define these macro functions in PL/SQL and call them from SQL for them to function as macros.

 **See Also:**

- [Conditions](#) for the syntax description of *condition*
- ["Selecting from a Partition: Example"](#)
- [Defining SQL Macros](#)

#### ***hierarchical\_query\_clause***

The `hierarchical_query_clause` lets you select rows in a hierarchical order.

SELECT statements that contain hierarchical queries can contain the `LEVEL` pseudocolumn in the select list. `LEVEL` returns the value 1 for a root node, 2 for a child node of a root node, 3 for a grandchild, and so on. The number of levels returned by a hierarchical query may be limited by available user memory.

Oracle processes hierarchical queries as follows:

- A join, if present, is evaluated first, whether the join is specified in the `FROM` clause or with `WHERE` clause predicates.
- The `CONNECT BY` condition is evaluated.
- Any remaining `WHERE` clause predicates are evaluated.

If you specify this clause, then do not specify either `ORDER BY` or `GROUP BY`, because they will destroy the hierarchical order of the `CONNECT BY` results. If you want to order rows of siblings of the same parent, then use the `ORDER SIBLINGS BY` clause.

#### See Also:

["Hierarchical Queries"](#) for a discussion of hierarchical queries and ["Using the LEVEL Pseudocolumn: Examples"](#)

### **START WITH Clause**

Specify a condition that identifies the row(s) to be used as the root(s) of a hierarchical query. The *condition* can be any condition as described in [Conditions](#). Oracle Database uses as root(s) all rows that satisfy this condition. If you omit this clause, then the database uses all rows in the table as root rows.

### **CONNECT BY Clause**

Specify a condition that identifies the relationship between parent rows and child rows of the hierarchy. The *condition* can be any condition as described in [Conditions](#). However, it must use the `PRIOR` operator to refer to the parent row.

#### See Also:

- [Pseudocolumns](#) for more information on `LEVEL`
- ["Hierarchical Queries"](#) for general information on hierarchical queries
- ["Hierarchical Query: Examples"](#)

### ***group\_by\_clause***

Specify the `GROUP BY` clause if you want the database to group the selected rows based on the value of `expr`(s) for each row and return a single row of summary information for each group. If this clause contains `CUBE` or `ROLLUP` extensions, then the database produces superaggregate groupings in addition to the regular groupings.

Expressions in the `GROUP BY` clause can contain any columns of the tables, views, or materialized views in the `FROM` clause, regardless of whether the columns appear in the select list.

The `GROUP BY` clause groups rows but does not guarantee the order of the result set. To order the groupings, use the `ORDER BY` clause.

If a column name in the source tables and column alias in the `SELECT` list are the same, `GROUP BY` will interpret the identifier as the column name, not the alias.

#### See Also:

- *Oracle Database Data Warehousing Guide* for an expanded discussion and examples of using SQL grouping syntax for data aggregation
- the `GROUP_ID`, `GROUPING`, and `GROUPING_ID` functions for examples
- "Using the GROUP BY Clause: Examples"
- [Restrictions for Linguistic Collations](#) for information on implications of how `GROUP BY` character values are compared linguistically
- Appendix C in *Oracle Database Globalization Support Guide* for the collation determination rules for the expressions in the `GROUP BY` clause

## ROLLUP

The `ROLLUP` operation in the `simple_grouping_clause` groups the selected rows based on the values of the first  $n$ ,  $n-1$ ,  $n-2$ , ... 0 expressions in the `GROUP BY` specification, and returns a single row of summary for each group. You can use the `ROLLUP` operation to produce **subtotal values** by using it with the `SUM` function. When used with `SUM`, `ROLLUP` generates subtotals from the most detailed level to the grand total. Aggregate functions such as `COUNT` can be used to produce other kinds of superaggregates.

For example, given three expressions ( $n=3$ ) in the `ROLLUP` clause of the `simple_grouping_clause`, the operation results in  $n+1 = 3+1 = 4$  groupings.

Rows grouped on the values of the first  $n$  expressions are called **regular rows**, and the others are called **superaggregate rows**.

#### See Also:

- Oracle Database Data Warehousing Guide* for information on using `ROLLUP` with materialized views

## CUBE

The `CUBE` operation in the `simple_grouping_clause` groups the selected rows based on the values of all possible combinations of expressions in the specification. It returns a single row of summary information for each group. You can use the `CUBE` operation to produce **cross-tabulation values**.

For example, given three expressions ( $n=3$ ) in the `CUBE` clause of the `simple_grouping_clause`, the operation results in  $2^n = 2^3 = 8$  groupings. Rows grouped on the values of  $n$  expressions are called **regular rows**, and the rest are called **superaggregate rows**.

 See Also:

- *Oracle Database Data Warehousing Guide* for information on using CUBE with materialized views
- "[Using the GROUP BY CUBE Clause: Example](#)"

## GROUPING SETS

GROUPING SETS are a further extension of the GROUP BY clause that let you specify multiple groupings of data. Doing so facilitates efficient aggregation by pruning the aggregates you do not need. You specify just the desired groups, and the database does not need to perform the full set of aggregations generated by CUBE or ROLLUP. Oracle Database computes all groupings specified in the GROUPING SETS clause and combines the results of individual groupings with a UNION ALL operation. The UNION ALL means that the result set can include duplicate rows.

Within the GROUP BY clause, you can combine expressions in various ways:

- To specify **composite columns**, group columns within parentheses so that the database treats them as a unit while computing ROLLUP or CUBE operations.
- To specify **concatenated grouping sets**, separate multiple grouping sets, ROLLUP, and CUBE operations with commas so that the database combines them into a single GROUP BY clause. The result is a cross-product of groupings from each grouping set.

 See Also:

- "[Using the GROUPING SETS Clause: Example](#)"

## HAVING Clause

Use the HAVING clause to restrict the groups of returned rows to those groups for which the specified *condition* is TRUE. If you omit this clause, then the database returns summary rows for all groups.

Specify GROUP BY and HAVING after the *where\_clause* and *hierarchical\_query\_clause*. If you specify both GROUP BY and HAVING, then they can appear in either order.

With Oracle Database 21c you can write macros for scalar expressions and use them inside the HAVING clause, where it would be legal to call a PL/SQL function.

You must define these macro functions in PL/SQL and call them from SQL for them to function as macros.

 See Also:

- ["Using the HAVING Condition: Example"](#)
- Defining SQL Macros

### Restrictions on the GROUP BY Clause

This clause is subject to the following restrictions:

- You cannot specify LOB columns, nested tables, or varrays as part of `expr`.
- The expressions can be of any form except scalar subquery expressions.
- If the `group_by_clause` references any object type columns, then the query will not be parallelized.
- To group by position, the parameter `group_by_position_enabled` must be set to true, this is false by default

### ***model\_clause***

The `model_clause` lets you view selected rows as a multidimensional array and randomly access cells within that array. Using the `model_clause`, you can specify a series of cell assignments, referred to as **rules**, that invoke calculations on individual cells and ranges of cells. These rules operate on the results of a query and do not update any database tables.

When using the `model_clause` in a query, the `SELECT` and `ORDER BY` clauses must refer only to those columns defined in the `model_column_clauses`.

 See Also:

- The syntax description of `expr` in "About SQL Expressions" and the syntax description of `condition` in [Conditions](#)
- *Oracle Database Data Warehousing Guide* for an expanded discussion and examples
- ["The MODEL clause: Examples"](#)

### ***main\_model***

The `main_model` clause defines how the selected rows will be viewed in a multidimensional array and what rules will operate on which cells in that array.

### ***model\_column\_clauses***

The `model_column_clauses` define and classify the columns of a query into three groups: partition columns, dimension columns, and measure columns. For `expr`, you can specify a column, constant, host variable, single-row function, aggregate function, or any expression involving them. If `expr` is a column, then the column alias (`c_alias`) is optional. If `expr` is not a column, then the column alias is required. If you specify a column alias, then you must use the alias to refer to the column in the `model_rules_clause`, `SELECT` list, and the query `ORDER BY` clauses.

## PARTITION BY

The PARTITION BY clause specifies the columns that will be used to divide the selected rows into partitions based on the values of the specified columns.

## DIMENSION BY

The DIMENSION BY clause specifies the columns that will identify a row within a partition. The values of the dimension columns, along with those of the partition columns, serve as array indexes to the measure columns within a row.

## MEASURES

The MEASURES clause identifies the columns on which the calculations can be performed. Measure columns in individual rows are treated like cells that you can reference, by specifying the values for the partition and dimension columns, and update.

### *cell\_reference\_options*

Use the *cell\_reference\_options* clause to specify how null and absent values are treated in rules and how column uniqueness is constrained.

### IGNORE NAV

When you specify IGNORE NAV, the database returns the following values for the null and absent values of the data type specified:

- Zero for numeric data types
- 01-JAN-2000 for datetime data types
- An empty string for character data types
- Null for all other data types

### KEEP NAV

When you specify KEEP NAV, the database returns null for both null and absent cell values. KEEP NAV is the default.

### UNIQUE SINGLE REFERENCE

When you specify UNIQUE SINGLE REFERENCE, the database checks only single-cell references on the right-hand side of the rule for uniqueness, not the entire query result set.

### UNIQUE DIMENSION

When you specify UNIQUE DIMENSION, the database checks that the PARTITION BY and DIMENSION BY columns form a unique key to the query. UNIQUE DIMENSION is the default.

### *model\_rules\_clause*

Use the *model\_rules\_clause* to specify the cells to be updated, the rules for updating those cells, and optionally, how the rules are to be applied and processed.

Each rule represents an assignment and consists of a left-hand side and right-hand side. The left-hand side of the rule identifies the cells to be updated by the right-hand side of the rule. The right-hand side of the rule evaluates to the values to be assigned to the cells specified on the left-hand side of the rule.

## UPSERT ALL

UPSERT ALL allows UPSERT behavior for a rule with both positional and symbolic references on the left-hand side of the rule. When evaluating an UPSERT ALL rule, Oracle performs the following steps to create a list of cell references to be upserted:

1. Find the existing cells that satisfy all the symbolic predicates of the cell reference.
2. Using just the dimensions that have symbolic references, find the distinct dimension value combinations of these cells.
3. Perform a cross product of these value combinations with the dimension values specified by way of positional references.

Refer to *Oracle Database Data Warehousing Guide* for more information on the semantics of UPSERT ALL.

## UPSERT

When you specify UPSERT, the database applies the rules to those cells referenced on the left-hand side of the rule that exist in the multidimensional array, and inserts new rows for those that do not exist. UPSERT behavior applies only when positional referencing is used on the left-hand side and a single cell is referenced. UPSERT is the default. Refer to [cell\\_assignment](#) for more information on positional referencing and single-cell references.

UPDATE and UPSERT can be specified for individual rules as well. When either UPDATE or UPSERT is specified for a specific rule, it takes precedence over the option specified in the RULES clause.

### Note:

If an UPSERT ALL, UPSERT, or UPDATE rule does not contain the appropriate predicates, then the database may implicitly convert it to a different type of rule:

- If an UPSERT rule contains an existential predicate, then the rule is treated as an UPDATE rule.
- An UPSERT ALL rule must have at least one existential predicate and one qualified predicate on its left side. If it has no existential predicate, then it is treated as an UPSERT rule. If it has no qualified predicate, then it is treated as an UPDATE rule

## UPDATE

When you specify UPDATE, the database applies the rules to those cells referenced on the left-hand side of the rule that exist in the multidimensional array. If the cells do not exist, then the assignment is ignored.

## AUTOMATIC ORDER

When you specify AUTOMATIC ORDER, the database evaluates the rules based on their dependency order. In this case, a cell can be assigned a value once only.

## SEQUENTIAL ORDER

When you specify SEQUENTIAL ORDER, the database evaluates the rules in the order they appear. In this case, a cell can be assigned a value more than once. SEQUENTIAL ORDER is the default.

### ITERATE ... [UNTIL]

Use ITERATE ... [UNTIL] to specify the number of times to cycle through the rules and, optionally, an early termination condition. The parentheses around the UNTIL condition are optional.

When you specify ITERATE ... [UNTIL], rules are evaluated in the order in which they appear. Oracle Database returns an error if both AUTOMATIC ORDER and ITERATE ... [UNTIL] are specified in the *model\_rules\_clause*.

### *cell\_assignment*

The *cell\_assignment* clause, which is the left-hand side of the rule, specifies one or more cells to be updated. When a *cell\_assignment* references a single cell, it is called a **single-cell reference**. When more than one cell is referenced, it is called a **multiple-cell reference**.

All dimension columns defined in the *model\_clause* must be qualified in the *cell\_assignment* clause. A dimension can be qualified using either symbolic or positional referencing.

A **symbolic reference** qualifies a single dimension column using a Boolean condition like *dimension\_column=constant*. A **positional reference** is one where the dimension column is implied by its position in the DIMENSION BY clause. The only difference between symbolic references and positional references is in the treatment of nulls.

Using a single-cell symbolic reference such as *a[x=null,y=2000]*, no cells qualify because *x=null* evaluates to FALSE. However, using a single-cell positional reference such as *a[null,2000]*, a cell where *x* is null and *y* is 2000 qualifies because *null = null* evaluates to TRUE. With single-cell positional referencing, you can reference, update, and insert cells where dimension columns are null.

You can specify a condition or an expression representing a dimension column value using either symbolic or positional referencing. *condition* cannot contain aggregate functions or the CV function, and *condition* must reference a single dimension column. *expr* cannot contain a subquery. Refer to "Model Expressions" for information on model expressions.

### *single\_column\_for\_loop*

The *single\_column\_for\_loop* clause lets you specify a range of cells to be updated within a single dimension column.

The IN clause lets you specify the values of the dimension column as either a list of values or as a subquery. When using *subquery*, it cannot:

- Be a correlated query
- Return more than 10,000 rows
- Be a query defined in the WITH clause

The FROM clause lets you specify a range of values for a dimension column with discrete increments within the range. The FROM clause can only be used for those

columns with a data type for which addition and subtraction is supported. The `INCREMENT` and `DECREMENT` values must be positive.

Optionally, you can specify the `LIKE` clause within the `FROM` clause. In the `LIKE` clause, `pattern` is a character string containing a single pattern-matching character `%`. This character is replaced during execution with the current incremented or decremented value in the `FROM` clause.

If all dimensions other than those used by a `FOR` loop involve a single-cell reference, then the expressions can insert new rows. The number of dimension value combinations generated by `FOR` loops is counted as part of the 10,000 row limit of the `MODEL` clause.

#### ***multi\_column\_for\_loop***

The `multi_column_for_loop` clause lets you specify a range of cells to be updated across multiple dimension columns. The `IN` clause lets you specify the values of the dimension columns as either multiple lists of values or as a subquery. When using `subquery`, it cannot:

- Be a correlated query
- Return more than 10,000 rows
- Be a query defined in the `WITH` clause

If all dimensions other than those used by a `FOR` loop involve a single-cell reference, then the expressions can insert new rows. The number of dimension value combinations generated by `FOR` loops is counted as part of the 10,000 row limit of the `MODEL` clause.

#### **See Also:**

*Oracle Database Data Warehousing Guide* for more information about using `FOR` loops in the `MODEL` clause

#### ***order\_by\_clause***

Use the `ORDER BY` clause to specify the order in which cells on the left-hand side of the rule are to be evaluated. The `expr` must resolve to a dimension or measure column. If the `ORDER BY` clause is not specified, then the order defaults to the order of the columns as specified in the `DIMENSION BY` clause. See ["order\\_by\\_clause"](#) for more information.

#### **Restrictions on the `order_by_clause`**

Use of the `ORDER BY` clause in the model rule is subject to the following restrictions:

- You cannot specify `SIBLINGS`, `position`, or `c_alias` in the `order_by_clause` of the `model_clause`.
- You cannot specify this clause on the left-hand side of the model rule and also specify a `FOR` loop on the right-hand side of the rule.

#### ***expr***

Specify an expression representing the value or values of the cell or cells specified on the right-hand side of the rule. `expr` cannot contain a subquery. Refer to "["Model Expressions"](#)" for information on model expressions.

#### ***return\_rows\_clause***

The *return\_rows\_clause* lets you specify whether to return all rows selected or only those rows updated by the model rules. **ALL** is the default.

#### **reference\_model**

Use the *reference\_model* clause when you need to access multiple arrays from inside the *model\_clause*. This clause defines a read-only multidimensional array based on the results of a query.

The subclauses of the *reference\_model* clause have the same semantics as for the *main\_model* clause. Refer to [model\\_column\\_clauses](#) and [cell\\_reference\\_options](#).

#### **Restrictions on the *reference\_model* Clause**

This clause is subject to the following restrictions:

- PARTITION BY columns cannot be specified for reference models.
- The subquery of the reference model cannot refer to columns in an outer subquery.

#### **Set Operators: (UNION, INTERSECT, MINUS, EXCEPT) ALL**

The set operators combine the rows returned by two **SELECT** statements into a single result. The number and data types of the columns selected by each component query must be the same, but the column lengths can be different. The names of the columns in the result set are the names of the expressions in the select list preceding the set operator.

If you combine more than two queries with set operators, then the database evaluates adjacent queries from left to right. The parentheses around the subquery are optional. You can use them to specify a different order of evaluation.

Refer to "[The Set Operators](#)" for information on these operators, including restrictions on their use.

#### **order\_by\_clause**

Use the **ORDER BY** clause to order rows returned by the statement. Without an *order\_by\_clause*, no guarantee exists that the same query executed more than once will retrieve rows in the same order.

#### **SIBLINGS**

The **SIBLINGS** keyword is valid only if you also specify the *hierarchical\_query\_clause* (**CONNECT BY**). **ORDER SIBLINGS BY** preserves any ordering specified in the hierarchical query clause and then applies the *order\_by\_clause* to the siblings of the hierarchy.

#### **expr**

*expr* orders rows based on their value for *expr*. The expression is based on columns in the select list or columns in the tables, views, or materialized views in the **FROM** clause.

#### **position**

Specify *position* to order rows based on their value for the expression in this position of the select list. The *position* value must be an integer.

You can specify multiple expressions in the `order_by_clause`. Oracle Database first sorts rows based on their values for the first expression. Rows with the same value for the first expression are then sorted based on their values for the second expression, and so on. The database sorts nulls following all others in ascending order and preceding all others in descending order. Refer to "[Sorting Query Results](#)" for a discussion of ordering query results.

### ASC | DESC

Specify whether the ordering sequence is ascending or descending. `ASC` is the default.

### NULS FIRST | NULS LAST

Specify whether returned rows containing null values should appear first or last in the ordering sequence.

`NULS LAST` is the default for ascending order, and `NULS FIRST` is the default for descending order.

### Restrictions on the ORDER BY Clause

The following restrictions apply to the `ORDER BY` clause:

- If you have specified the `DISTINCT` operator in this statement, then this clause cannot refer to columns unless they appear in the select list.
- An `order_by_clause` can contain no more than 255 expressions.
- You cannot order by a LOB, `LONG`, or `LONG RAW` column, nested table, or varray.
- If you specify a `group_by_clause` in the same statement, then this `order_by_clause` is restricted to the following expressions:
  - Constants
  - Aggregate functions
  - Analytic functions
  - The functions `USER`, `UID`, and `SYSDATE`
  - Expressions identical to those in the `group_by_clause`
  - Expressions comprising the preceding expressions that evaluate to the same value for all rows in a group

#### See Also:

- "[Using the ORDER BY Clause: Examples](#)"
- [Restrictions for Linguistic Collations](#) for information on implications of how `ORDER BY` character values are compared linguistically
- Appendix C in *Oracle Database Globalization Support Guide* for the collation determination rules for the expressions in the `ORDER BY` clause

### `window_clause`

Oracle Database Release 21c supports the `window_clause` in the `query_block` clause.

### Rules

- If you use a new *window\_specification* to specify an *existing\_window\_name* then
  - *existing\_window\_name* must refer to an earlier entry in the *window\_name* list
  - You cannot use *existing\_window\_name* with *windowing\_clause*
  - You cannot define a new window with the *query\_partition\_clause*. If *existing\_window\_name* has *order\_by\_clause*, then the new window definition cannot have *order\_by\_clause*.
- You cannot use the *model\_clause* with *window\_clause*.
- Note that `OVER window_name` is not equivalent to `OVER (window_name ...)`. `OVER (window_name ...)` implies copying and modifying the window specification, and will be rejected if the referenced window specification includes a *windowing\_clause*.

### Example

The following query shows the usage of *window\_clause* specified as part of table expression and window functions specified using the window name as defined in *window clause*.

```
SELECT
    ename, mgr,
    FIRST_VALUE(sal) OVER w AS 'first',
    LAST_VALUE(sal) OVER w AS 'last',
    NTH_VALUE(sal, 2) OVER w AS 'second',
    NTH_VALUE(sal, 4) OVER w AS 'fourth'
FROM emp
WINDOW w AS (PARTITION BY deptno ORDER BY sal ROWS UNBOUNDED PRECEDING);
```

### *row\_limiting\_clause*

The *row\_limiting\_clause* allows you to limit the rows returned by the query. You can specify an offset, and the number of rows or percentage of rows to return. You can use this clause to implement top-N reporting. For consistent results, specify the *order\_by\_clause* to ensure a deterministic sort order.

### OFFSET

Use this clause to specify the number of rows to skip before row limiting begins. *offset* must be a number or an expression that evaluates to a numeric value. If you specify a negative number, then *offset* is treated as 0. If you specify NULL, or a number greater than or equal to the number of rows returned by the query, then 0 rows are returned. If *offset* includes a fraction, then the fractional portion is truncated. If you do not specify this clause, then *offset* is 0 and row limiting begins with the first row.

### ROW | ROWS

These keywords can be used interchangeably and are provided for semantic clarity.

### FETCH

Use this clause to specify the number of rows or percentage of rows to return. If you do not specify this clause, then all rows are returned, beginning at row *offset* + 1.

### FIRST | NEXT

These keywords can be used interchangeably and are provided for semantic clarity.

### *rowcount* | *percent* PERCENT

Use *rowcount* to specify the number of rows to return. *rowcount* must be a number or an expression that evaluates to a numeric value. If you specify a negative number, then *rowcount* is treated as 0. If *rowcount* is greater than the number of rows available beginning at row *offset* + 1, then all available rows are returned. If *rowcount* includes a fraction, then the fractional portion is truncated. If *rowcount* is NULL, then 0 rows are returned.

Use *percent PERCENT* to specify the percentage of the total number of selected rows to return. *percent* must be a number or an expression that evaluates to a numeric value. If you specify a negative number, then *percent* is treated as 0. If *percent* is NULL, then 0 rows are returned.

If you do not specify *rowcount* or *percent PERCENT*, then 1 row is returned.

## ROW | ROWS

These keywords can be used interchangeably and are provided for semantic clarity.

## ONLY | WITH TIES

Specify *ONLY* to return exactly the specified number of rows or percentage of rows.

Specify *WITH TIES* to return additional rows with the same sort key as the last row fetched. If you specify *WITH TIES*, then you must specify the *order\_by\_clause*. If you do not specify the *order\_by\_clause*, then no additional rows will be returned.

### Restrictions on the *row\_limiting\_clause*

This clause is subject to the following restrictions:

- You cannot specify this clause with the *for\_update\_clause*.
- If you specify this clause, then the select list cannot contain the sequence pseudocolumns CURRVAL or NEXTVAL.
- Materialized views are not eligible for an incremental refresh if the defining query contains the *row\_limiting\_clause*.
- If the select list contains columns with identical names and you specify the *row\_limiting\_clause*, then an ORA-00918 error occurs. This error occurs whether the identically named columns are in the same table or in different tables. You can work around this issue by specifying unique column aliases for the identically named columns.

### See Also:

"Row Limiting: Examples"

## *for\_update\_clause*

The *FOR UPDATE* clause lets you lock the selected rows so that other users cannot lock or update the rows until you end your transaction. You can specify this clause only in a top-level SELECT statement, not in subqueries.

 **Note:**

Prior to updating a LOB value, you must lock the row containing the LOB. One way to lock the row is with an embedded `SELECT ... FOR UPDATE` statement. You can do this using one of the programmatic languages or `DBMS_LOB` package. For more information on lock rows before writing to a LOB, see *Oracle Database SecureFiles and Large Objects Developer's Guide*.

Nested table rows are not locked as a result of locking the parent table rows. If you want the nested table rows to be locked, then you must lock them explicitly.

### Restrictions on the FOR UPDATE Clause

This clause is subject to the following restrictions:

- You cannot specify this clause with the following other constructs: the `DISTINCT` operator, `CURSOR` expression, set operators, `group_by_clause`, or aggregate functions.
- The tables locked by this clause must all be located on the same database and on the same database as any `LONG` columns and sequences referenced in the same statement.

 **See Also:**

["Using the FOR UPDATE Clause: Examples"](#)

### Using the FOR UPDATE Clause on Views

In general, this clause is not supported on views. However, in some cases, a `SELECT ... FOR UPDATE` query on a view can succeed without any errors. This occurs when the view has been merged to its containing query block internally by the query optimizer, and `SELECT ... FOR UPDATE` succeeds on the internally transformed query. The examples in this section illustrate when using the `FOR UPDATE` clause on a view can succeed or fail.

- Using the `FOR UPDATE` clause on merged views

An error can occur when you use the `FOR UPDATE` clause on a merged view if both of the following conditions apply:

- The underlying column of the view is an expression
- The `FOR UPDATE` clause applies to a column list

The following statement succeeds because the underlying column of the view is not an expression:

```
SELECT employee_id FROM (SELECT * FROM employees)
    FOR UPDATE OF employee_id;
```

The following statement succeeds because, while the underlying column of the view is an expression, the `FOR UPDATE` clause does not apply to a column list:

```
SELECT employee_id FROM (SELECT employee_id+1 AS employee_id FROM employees)
FOR UPDATE;
```

The following statement fails because the underlying column of the view is an expression and the FOR UPDATE clause applies to a column list:

```
SELECT employee_id FROM (SELECT employee_id+1 AS employee_id FROM employees)
FOR UPDATE OF employee_id;
*
Error at line 2:
ORA-01733: virtual column not allowed here
```

- Using the FOR UPDATE clause on non-merged views

Since the FOR UPDATE clause is not supported on views, anything that prevents view merging, such as the NO\_MERGE hint, parameters that disallow view merging, or something in the query structure that prevents view merging, will result in an ORA-02014 error.

In the following example, the GROUP BY statement prevents view merging, which causes an error:

```
SELECT avgsal
      FROM (SELECT AVG(salary) AS avgsal FROM employees GROUP BY job_id)
            FOR UPDATE;
      FROM (SELECT AVG(salary) AS avgsal FROM employees GROUP BY job_id)
            *
ERROR at line 2:
ORA-02014: cannot select FOR UPDATE from view with DISTINCT, GROUP BY, etc.
```

 **Note:**

Due to the complexity of the view merging mechanism, Oracle recommends against using the FOR UPDATE clause on views.

### OF ... column

Use the OF ... column clause to lock the select rows only for a particular table or view in a join. The columns in the OF clause only indicate which table or view rows are locked. The specific columns that you specify are not significant. However, you must specify an actual column name, not a column alias. If you omit this clause, then the database locks the selected rows from all the tables in the query.

### NOWAIT | WAIT

The NOWAIT and WAIT clauses let you tell the database how to proceed if the SELECT statement attempts to lock a row that is locked by another user.

- Specify NOWAIT to return control to you immediately if a lock exists.
- Specify WAIT to instruct the database to wait *integer* seconds for the row to become available and then return control to you.

If you specify neither WAIT nor NOWAIT, then the database waits until the row is available and then returns the results of the SELECT statement.

### SKIP LOCKED

SKIP LOCKED is an alternative way to handle a contending transaction that is locking some rows of interest. Specify SKIP LOCKED to instruct the database to attempt to lock the rows specified by the WHERE clause and to skip any rows that are found to be already locked by another transaction. This feature is designed for use in multiconsumer queue environments. It enables queue consumers to skip rows that are locked by other consumers and obtain unlocked rows without waiting for the other consumers to finish. Refer to *Oracle Database Advanced Queuing User's Guide* for more information.

#### Note on the WAIT and SKIP LOCKED Clauses

If you specify WAIT or SKIP LOCKED and the table is locked in exclusive mode, then the database will not return the results of the SELECT statement until the lock on the table is released. In the case of WAIT, the SELECT FOR UPDATE clause is blocked regardless of the wait time specified.

#### *row\_pattern\_clause*

The MATCH\_RECOGNIZE clause lets you perform pattern matching. Use this clause to recognize patterns in a sequence of rows in *table*, which is called the row pattern input table. The result of a query that uses the MATCH\_RECOGNIZE clause is called the row pattern output table.

The MATCH\_RECOGNIZE enables you to do the following tasks:

- Logically partition and order the data with the PARTITION BY and ORDER BY clauses.
- Define measures, which are expressions usable in other parts of the SQL query, in the MEASURES clause.
- Define patterns of rows to seek using the PATTERN clause. These patterns use regular expression syntax, a powerful and expressive feature, applied to the pattern variables you define.
- Specify the logical conditions required to map a row to a row pattern variable in the DEFINE clause.

#### See Also:

- *Oracle Database Data Warehousing Guide* for more information on pattern matching
- "[Row Pattern Matching: Example](#)"

#### *row\_pattern\_partition\_by*

Specify PARTITION BY to divide the rows in the row pattern input table into logical groups called row pattern partitions. Use *column* to specify one or more partitioning columns. Each partition consists of the set of rows in the row pattern input table that have the same value(s) on the partitioning column(s).

If you specify this clause, then matches are found within partitions and do not cross partition boundaries. If you do not specify this clause, then all rows of the row input table constitute a single row pattern partition.

### ***row\_pattern\_order\_by***

Specify ORDER BY to order rows within each row pattern partition. Use *column* to specify one or more ordering columns. If you specify multiple columns, then Oracle Database first sorts rows based on their values for the first column. Rows with the same value for the first column are then sorted based on their values for the second column, and so on. Oracle Database sorts nulls following all others in ascending order.

If you do not specify this clause, then the result of the *row\_pattern\_clause* is nondeterministic and you may get inconsistent results each time you run the query.

### ***row\_pattern\_measures***

Use the MEASURES clause to define one or more row pattern measure columns. These columns are included in the row pattern output table and contain values that are useful for analyzing data.

When you define a row pattern measure column, using the *row\_pattern\_measure\_column* clause, you specify its pattern measure expression. The values in the column are calculated by evaluating the pattern measure expression whenever a match is found.

### ***row\_pattern\_measure\_column***

Use this clause to define a row pattern measure column.

- For *expr*, specify the pattern measure expression. A pattern measure expression is an expression as described in [Expressions](#) that can contain only the following elements:
  - Constants: Text literals and numeric literals
  - References to any column of the row pattern input table
  - The CLASSIFIER function, which returns the name of the primary row pattern variable to which the row is mapped. Refer to [row\\_pattern\\_classifier\\_func](#) for more information.
  - The MATCH\_NUMBER function, which returns the sequential number of a row pattern match within the row pattern partition. Refer to [row\\_pattern\\_match\\_num\\_func](#) for more information.
  - Row pattern navigation functions: PREV, NEXT, FIRST, and LAST. Refer to [row\\_pattern\\_navigation\\_func](#) for more information.
  - Row pattern aggregate functions: AVG , COUNT , MAX , MIN , or SUM . Refer to [row\\_pattern\\_aggregate\\_func](#) for more information.
- For *c\_alias*, specify the alias for the pattern measure expression. Oracle Database uses this alias in the column heading of the row pattern output table. The AS keyword is optional. The alias can be used in other parts of the query, such as the SELECT ... ORDER BY clause.

### ***row\_pattern\_rows\_per\_match***

This clause lets you specify whether the row pattern output table includes summary or detailed data about each match.

- If you specify ONE ROW PER MATCH, then each match produces one summary row. This is the default.

- If you specify ALL ROWS PER MATCH, then each match that spans multiple rows will produce one output row for each row in the match.

#### ***row\_pattern\_skip\_to***

This clause lets you specify the point to resume row pattern matching after a non-empty match is found.

- Specify AFTER MATCH SKIP TO NEXT ROW to resume pattern matching at the row after the first row of the current match.
- Specify AFTER MATCH SKIP PAST LAST ROW to resume pattern matching at the next row after the last row of the current match. This is the default.
- Specify AFTER MATCH SKIP TO FIRST *variable\_name* to resume pattern matching at the first row that is mapped to pattern variable *variable\_name*. The *variable\_name* must be defined in the DEFINE clause.
- Specify AFTER MATCH SKIP TO LAST *variable\_name* to resume pattern matching at the last row that is mapped to pattern variable *variable\_name*. The *variable\_name* must be defined in the DEFINE clause.
- AFTER MATCH SKIP TO *variable\_name* has the same behavior as AFTER MATCH SKIP TO LAST *variable\_name*.

#### **See Also:**

*Oracle Database Data Warehousing Guide* for more information on the AFTER MATCH SKIP clauses

## **PATTERN**

Use the PATTERN clause to define which pattern variables must be matched, the sequence in which they must be matched, and the quantity of rows that must be matched for each pattern variable.

A row pattern match consists of a set of contiguous rows in a row pattern partition. Each row of the match is mapped to a pattern variable. The mapping of rows to pattern variables must conform to the regular expression specified in the *row\_pattern* clause, and all conditions in the DEFINE clause must be true.

#### **Note:**

It is outside the scope of this document to explain regular expression concepts and details. If you are not familiar with regular expressions, then you are encouraged to familiarize yourself with the topic using other sources.

The precedence of the elements that you specify in the regular expression of the PATTERNS clause, in decreasing order, is as follows:

- Row pattern elements (specified in the *row\_pattern\_primary* clause)
- Row pattern quantifiers (specified in the *row\_pattern\_quantifier* clause)

- Concatenation (specified in the `row_pattern_term` clause)
- Alternation (specified in the `row_pattern` clause)

### See Also:

*Oracle Database Data Warehousing Guide* for more information on the PATTERN clause

## `row_pattern`

Use this clause to specify the row pattern. A row pattern is a regular expression that can take one of the following forms:

- A single row pattern term
  - For example: PATTERN (A)
- A row pattern, a vertical bar, and a row pattern term
  - For example: PATTERN (A | B)
- A recursively built row pattern, a vertical bar, and a row pattern term
  - For example: PATTERN (A | B | C)

The vertical bar in this clause represents **alternation**. Alternation matches a single regular expression from a list of several possible regular expressions. Alternatives are preferred in the order they are specified. For example, if you specify PATTERN (A | B | C), then Oracle Database attempts to match A first. If A is not matched, then it attempts to match B. If B is not matched, then it attempts to match C.

## `row_pattern_term`

This clause lets you specify a row pattern term. A row pattern term can take one of the following forms:

- A single row pattern factor
  - For example: PATTERN (A)
- A row pattern term followed by a row pattern factor.
  - For example: PATTERN (A B)
- A recursively built row pattern term followed by a row pattern factor
  - For example: PATTERN (A B C)

The syntax used in the second and third examples represents **concatenation**. Concatenation is used to list two or more items in a pattern to be matched and the order in which they are to be matched. For example, if you specify PATTERN (A B C), then Oracle Database first matches A, then uses the resulting matched rows to match B, then uses the resulting matched rows to match C. Only rows that match A, B, and C, are included in the row pattern match.

## `row_pattern_factor`

This clause lets you specify a row pattern factor. A row pattern factor consists of a row pattern element, specified using the `row_pattern_primary` clause, and an optional row pattern quantifier, specified using the `row_pattern_quantifier` clause.

***row\_pattern\_primary***

Use this clause to specify the row pattern element. [Table 19-1](#) lists the valid row pattern elements and their descriptions.

**Table 19-1 Row Pattern Elements**

| Row Pattern Element              | Description                                                                                                                                                                                                                |
|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>variable_name</code>       | Specify a primary pattern variable name that is defined in the <code>row_pattern_definition</code> clause. You cannot specify a union pattern variable that is defined in the <code>row_pattern_subset_item</code> clause. |
| <code>\$</code>                  | <code>\$</code> matches the position after the last row in the partition. This element is an anchor. Anchors work in terms of positions rather than rows.                                                                  |
| <code>^</code>                   | <code>^</code> matches the position before the first row in the partition. This element is an anchor. Anchors work in terms of positions rather than rows                                                                  |
| <code>( [row_pattern] )</code>   | Use <code>row_pattern</code> to specify the row pattern to be matched. An empty pattern <code>()</code> matches an empty set of rows.                                                                                      |
| <code>{- row_pattern -}</code>   | Exclusion syntax. Use <code>row_pattern</code> to specify parts of the pattern to be excluded from the output of ALL ROWS PER MATCH.                                                                                       |
| <code>row_pattern_permute</code> | Use <code>row_pattern_permute</code> to specify a pattern that is a permutation of row pattern elements. Refer to <a href="#">row_pattern_permute</a> for the full semantics of this clause.                               |

***row\_pattern\_permute***

Use the PERMUTE clause to express a pattern that is a permutation of the specified row pattern elements. For example, `PATTERN (PERMUTE (A, B, C))` is equivalent to an alternation of all permutations of the three row pattern elements A, B, and C, similar to the following:

```
PATTERN (A B C | A C B | B A C | B C A | C A B | C B A)
```

Note that the row pattern elements are expanded lexicographically and that each element to permute must be separated by a comma from the other elements.

 **See Also:**

[Oracle Database Data Warehousing Guide](#) for more information on permutations

***row\_pattern\_quantifier***

Use this clause to specify the row pattern quantifier, which is a postfix operator that defines the number of iterations accepted for a match.

Row pattern quantifiers are referred to as greedy; they will attempt to match as many instances of the regular expression on which they are applied as possible. The exception is row pattern quantifiers that have a question mark (?) as a suffix, which are

referred to as reluctant. They will attempt to match as few instances as possible of the regular expression on which they are applied.

**Table 19-2** lists the valid row pattern quantifiers and the number of iterations they accept for a match. In this table,  $n$  and  $m$  represent unsigned integers.

**Table 19-2 Row Pattern Quantifiers**

| Row Pattern Quantifier | Number of Iterations Accepted for a Match                                              |
|------------------------|----------------------------------------------------------------------------------------|
| *                      | 0 or more iterations (greedy)                                                          |
| *?                     | 0 or more iterations (reluctant)                                                       |
| +                      | 1 or more iterations (greedy)                                                          |
| +?                     | 1 or more iterations (reluctant)                                                       |
| ?                      | 0 or 1 iterations (greedy)                                                             |
| ??                     | 0 or 1 iterations (reluctant)                                                          |
| { $n$ ,}               | $n$ or more iterations, ( $n \geq 0$ ) (greedy)                                        |
| { $n$ ,} $n$ ?         | $n$ or more iterations, ( $n \geq 0$ ) (reluctant)                                     |

### ***row\_pattern\_subset\_clause***

The `SUBSET` clause lets you specify one or more union row pattern variables. Use the `row_pattern_subset_item` clause to declare each union row pattern variable.

You can specify union row pattern variables in the following clauses:

- `MEASURES` clause: In the expression for a row pattern measure column. That is, in expression `expr` of the `row_pattern_measure_column` clause.
- `DEFINE` clause: In the condition that defines a primary pattern variable. That is, in condition of the `row_pattern_definition` clause

### ***row\_pattern\_subset\_item***

This clause lets you create a grouping of multiple pattern variables that can be referred to with a variable name of its own. The variable name that refers to this grouping is called a union row pattern variable.

- For `variable_name` on the left side of the equal sign, specify the name of the union row pattern variable.
- On the right side of the equal sign, specify a comma-separated list of distinct primary row pattern variables within parentheses. This list cannot include any union row pattern variables.

 **See Also:**

*Oracle Database Data Warehousing Guide* for more information on defining union row pattern variables

## DEFINE

Use the `DEFINE` clause to specify one or more row pattern definitions. A row pattern definition specifies the conditions that a row must meet in order to be mapped to a specific pattern variable.

The `DEFINE` clause only supports running semantics.

 **See Also:**

- *Oracle Database Data Warehousing Guide* for more information on the `DEFINE` clause
- *Oracle Database Data Warehousing Guide* for more information on running and final semantics

### ***row\_pattern\_definition\_list***

This clause lets you specify one or more row pattern definitions.

### ***row\_pattern\_definition***

This clause lets you specify a row pattern definition, which contains the conditions that a row must meet in order to be mapped to the specified pattern variable.

- For `variable_name`, specify the name of the pattern variable.
- For `condition`, specify a condition as described in [Conditions](#), with the following extension: `condition` can contain any of the functions described by [`row\_pattern\_navigation\_func::=`](#) and [`row\_pattern\_aggregate\_func::=`](#).

### ***row\_pattern\_rec\_func***

This clause comprises the following clauses, which let you specify row pattern recognition functions:

- `row_pattern_classifier_func`: Use this clause to specify the `CLASSIFIER` function, which returns a character string whose value is the name of the variable to which the row is mapped.

- *row\_pattern\_match\_num\_func*: Use this clause to specify the MATCH\_NUMBER function, which returns a numeric value with scale 0 (zero) whose value is the sequential number of the match within the row pattern partition.
- *row\_pattern\_navigation\_func*: Use this clause to specify functions that perform row pattern navigation operations.
- *row\_pattern\_aggregate\_func*: Use this clause to specify an aggregate function in the expression for a row pattern measure column or in the condition that defines a primary pattern variable.

You can specify row pattern recognition functions in the following clauses:

- MEASURES clause: In the expression for a row pattern measure column. That is, in expression *expr* of the *row\_pattern\_measure\_column* clause.
- DEFINE clause: In the condition that defines a primary pattern variable. That is, in condition of the *row\_pattern\_definition* clause

A row pattern recognition function may behave differently depending whether you specify it in the MEASURES or DEFINE clause. These details are explained in the semantics for each clause.

#### ***row\_pattern\_classifier\_func***

The CLASSIFIER function returns a character string whose value is the name of the variable to which the row is mapped.

- In the MEASURES clause:
  - If you specify ONE ROW PER MATCH, then the query uses the last row of the match when processing the MEASURES clause, so the CLASSIFIER function returns the name of the pattern variable to which the last row of the match is mapped.
  - If you specify ALL ROWS PER MATCH, then for each row of the match found, the CLASSIFIER function returns the name of the pattern variable to which the row is mapped.

For empty matches—that is, matches that contain no rows, the CLASSIFIER function returns NULL.

- In the DEFINE clause, the CLASSIFIER function returns the name of the primary pattern variable to which the current row is mapped.

#### ***row\_pattern\_match\_num\_func***

The MATCH\_NUMBER function returns a numeric value with scale 0 (zero) whose value is the sequential number of the match within the row pattern partition.

Matches within a row pattern partition are numbered sequentially starting with 1 in the order in which they are found. If multiple rows satisfy a match, then they are all assigned the same match number. Note that match numbering starts over again at 1 in each row pattern partition, because there is no inherent ordering between row pattern partitions.

- In the MEASURES clause: You can use MATCH\_NUMBER to obtain the sequential number of the match within the row pattern.
- In the DEFINE clause: You can use MATCH\_NUMBER to define conditions that depend upon the match number.

#### ***row\_pattern\_navigation\_func***

This clause lets you perform the following row pattern navigation operations:

- Navigate among the group of rows mapped to a pattern variable using the FIRST and LAST functions of the `row_pattern_nav_logical` clause.
- Navigate among all rows in a row pattern partition using the PREV and NEXT functions of the `row_pattern_nav_physical` clause
- Nest the FIRST or LAST function within the PREV or NEXT function using the `row_pattern_nav_compound` clause.

#### ***row\_pattern\_nav\_logical***

This clause lets you use the FIRST and LAST functions to navigate among the group of rows mapped to a pattern variable using an optional logical offset.

- The FIRST function returns the value of expression `expr` when evaluated in the first row of the group of rows mapped to the pattern variable that is specified in `expr`. If no rows are mapped to the pattern variable, then the FIRST function returns NULL.
- The LAST function returns the value of expression `expr` when evaluated in the last row of the group of rows mapped to the pattern variable that is specified in `expr`. If no rows are mapped to the pattern variable, then the LAST function returns NULL.
- Use `expr` to specify the expression to be evaluated. It must contain at least one row pattern column reference. If it contains more than one row pattern column reference, then all must refer to the same pattern variable.
- Use the optional `offset` to specify the logical offset within the set of rows mapped to the pattern variable. When specified with the FIRST function, the offset is the number of rows from the first row, in ascending order. When specified with the LAST function, the offset is the number of rows from the last row in descending order. The default offset is 0.

For `offset`, specify a non-negative integer. It must be a runtime constant (literal, bind variable, or expressions involving them), but not a column or subquery.

If you specify an `offset` that is greater than or equal to the number of rows mapped to the pattern variable minus 1, then the function returns NULL.

You can specify running or final semantics for the FIRST and LAST functions as follows:

- The MEASURES clause supports running and final semantics. Specify RUNNING for running semantics. Specify FINAL for final semantics. The default is RUNNING.
- The DEFINE clause supports only running semantics. Therefore, running semantics will be used whether you specify or omit RUNNING. You cannot specify FINAL.

#### **See Also:**

- *Oracle Database Data Warehousing Guide* for more information on the FIRST and LAST functions
- *Oracle Database Data Warehousing Guide* for more information on running and final semantics

#### ***row\_pattern\_nav\_physical***

This clause lets you use the PREV and NEXT functions to navigate all rows in a row pattern partition using an optional physical offset.

- The `PREV` function returns the value of expression `expr` when evaluated in the previous row in the partition. If there is no previous row in the partition, then the `PREV` function returns `NULL`.
- The `NEXT` function returns the value of expression `expr` when evaluated in the next row in the partition. If there is no next row in the partition, then the `NEXT` function returns `NULL`.
- Use `expr` to specify the expression to be evaluated. It must contain at least one row pattern column reference. If it contains more than one row pattern column reference, then all must refer to the same pattern variable.
- Use the optional `offset` to specify the physical offset within the partition. When specified with the `PREV` function, it is the number of rows before the current row. When specified with the `NEXT` function, it is the number of rows after the current row. The default is 1. If you specify an offset of 0, then the current row is evaluated.

For `offset`, specify a non-negative integer. It must be a runtime constant (literal, bind variable, or expressions involving them), but not a column or subquery.

The `PREV` and `NEXT` functions always use running semantics. Therefore, you cannot specify the `RUNNING` or `FINAL` keywords with this clause.

#### See Also:

- *Oracle Database Data Warehousing Guide* for more information on the `PREV` and `NEXT` functions
- *Oracle Database Data Warehousing Guide* for more information on running and final semantics

#### ***row\_pattern\_nav\_compound***

This clause lets you nest the `row_pattern_nav_logical` clause within the `row_pattern_nav_physical` clause. That is, it lets you nest the `FIRST` or `LAST` function within the `PREV` or `NEXT` function. The `row_pattern_nav_logical` clause is evaluated first and then the result is supplied to the `row_pattern_nav_physical` clause.

Refer to `row_pattern_nav_logical` and `row_pattern_nav_physical` for the full semantics of these clauses.

#### See Also:

*Oracle Database Data Warehousing Guide* for more information on nesting the `FIRST` and `LAST` functions within the `PREV` and `NEXT` functions

#### ***row\_pattern\_aggregate\_func***

This clause lets you use an aggregate function in the expression for a row pattern measure column or in the condition that defines a primary pattern variable.

For `aggregate_function`, specify any one of the `AVG` , `COUNT` , `MAX` , `MIN` , or `SUM` functions. The `DISTINCT` keyword is not supported.

You can specify running or final semantics for aggregate functions as follows:

- The `MEASURES` clause supports running and final semantics. Specify `RUNNING` for running semantics. Specify `FINAL` for final semantics. The default is `RUNNING`.
- The `DEFINE` clause supports only running semantics. Therefore, running semantics will be used whether you specify or omit `RUNNING`. You cannot specify `FINAL`.

### See Also:

- *Oracle Database Data Warehousing Guide* for more information on aggregate functions
- *Oracle Database Data Warehousing Guide* for more information on running and final semantics

## Examples

### SQL Macros - Scalar Valued Macros: Examples

#### Print Hello <name>

A PL/SQL function `greet` is defined as a scalar SQL Macro that returns the string 'Hello, <name>! ' when called from a SQL SELECT statement.

```
create or replace function greet(name varchar2 default 'World')
    return varchar2 SQL_MACRO(Scalar) is
begin
    return q'{Hello, ' || name || '!' }';
end;
/
```

You can call `greet` in two ways:

**Option 1: Without passing an explicit argument** . In this case the default argument is used and 'Hello World' is returned.

```
SELECT greet ('World') from dual;
-----
Hello, World!
```

**Option 2: Passing an explicit argument** . In this case the argument passed is used and 'Hello Bob' is returned.

```
SELECT greet ('Bob') from dual;
-----
Hello, Bob!
```

#### Split String Based on Delimiter

The PL/SQL function `split_part` splits a string on the specified delimiter and returns the part at the specified position.

```
create or replace function split_part(string      varchar2,
                                      delimiter   varchar2,
                                      position    pls_integer)
    return varchar2 SQL_MACRO(Scalar) is
begin
```

```

        return q'{ 
            regexp_substr(replace(string, delimiter||delimiter, delimiter||' '||delimiter),
                          '[^'||delimiter||']+', 1, position, 'imx')
        }';
    end;
/
SELECT split_part( sysdate, '-', 2) month from dual;
-----
MONTH
-----
OCT

```

### SQL Macros - Table Valued Macros: Examples

The macro function `budget` computes the amount of each department's budget for a given job. It returns the number of employees in each department with the specified job title.

```

create or replace function budget(job varchar2) return varchar2 SQL_MACRO is
begin
    return q'{ 
        select deptno, sum(sal) budget
        from emp
        where job = budget.job
        group by deptno
    }';
end;
/

```

| DEPTNO | BUDGET |
|--------|--------|
| 20     | 2975   |
| 30     | 2850   |
| 10     | 2450   |

### Using a PL/SQL Function in the WITH Clause: Examples

The following example declares and defines a PL/SQL function `get_domain` in the `WITH` clause. The `get_domain` function returns the domain name from a URL string, assuming that the URL string has the "www" prefix immediately preceding the domain name, and the domain name is separated by dots on the left and right. The `SELECT` statement uses `get_domain` to find distinct catalog domain names from the `orders` table in the `oe` schema.

```

WITH
FUNCTION get_domain(url VARCHAR2) RETURN VARCHAR2 IS
    pos BINARY_INTEGER;
    len BINARY_INTEGER;
BEGIN
    pos := INSTR(url, 'www.');
    len := INSTR(SUBSTR(url, pos + 4), '.') - 1;
    RETURN SUBSTR(url, pos + 4, len);
END;
SELECT DISTINCT get_domain(catalog_url)
    FROM product_information;
/

```

### Subquery Factoring: Example

The following statement creates the query names `dept_costs` and `avg_cost` for the initial query block containing a join, and then uses the query names in the body of the main query.

```

WITH
    dept_costs AS (
        SELECT department_name, SUM(salary) dept_total
        FROM employees e, departments d
        WHERE e.department_id = d.department_id
        GROUP BY department_name),
    avg_cost AS (
        SELECT SUM(dept_total)/COUNT(*) avg
        FROM dept_costs)
SELECT * FROM dept_costs
WHERE dept_total >
    (SELECT avg FROM avg_cost)
ORDER BY department_name;

```

| DEPARTMENT_NAME | DEPT_TOTAL |
|-----------------|------------|
| Sales           | 304500     |
| Shipping        | 156400     |

### Recursive Subquery Factoring: Examples

The following statement shows the employees who directly or indirectly report to employee 101 and their reporting level.

```

WITH
    reports_to_101 (eid, emp_last, mgr_id, reportLevel) AS
    (
        SELECT employee_id, last_name, manager_id, 0 reportLevel
        FROM employees
        WHERE employee_id = 101
    UNION ALL
        SELECT e.employee_id, e.last_name, e.manager_id, reportLevel+1
        FROM reports_to_101 r, employees e
        WHERE r.eid = e.manager_id
    )
    SELECT eid, emp_last, mgr_id, reportLevel
    FROM reports_to_101
    ORDER BY reportLevel, eid;

```

| EID | EMP_LAST  | MGR_ID | REPORTLEVEL |
|-----|-----------|--------|-------------|
| 101 | Kochhar   | 100    | 0           |
| 108 | Greenberg | 101    | 1           |
| 200 | Whalen    | 101    | 1           |
| 203 | Mavris    | 101    | 1           |
| 204 | Baer      | 101    | 1           |
| 205 | Higgins   | 101    | 1           |
| 109 | Faviet    | 108    | 2           |
| 110 | Chen      | 108    | 2           |
| 111 | Sciarra   | 108    | 2           |
| 112 | Urman     | 108    | 2           |
| 113 | Popp      | 108    | 2           |
| 206 | Gietz     | 205    | 2           |

The following statement shows employees who directly or indirectly report to employee 101, their reporting level, and their management chain.

```

WITH
    reports_to_101 (eid, emp_last, mgr_id, reportLevel, mgr_list) AS
    (
        SELECT employee_id, last_name, manager_id, 0 reportLevel,

```

```

        CAST(manager_id AS VARCHAR2(2000))
  FROM employees
 WHERE employee_id = 101
UNION ALL
  SELECT e.employee_id, e.last_name, e.manager_id, reportLevel+1,
         CAST(mgr_list || ',' || manager_id AS VARCHAR2(2000))
   FROM reports_to_101 r, employees e
  WHERE r.eid = e.manager_id
)
SELECT eid, emp_last, mgr_id, reportLevel, mgr_list
FROM reports_to_101
ORDER BY reportLevel, eid;

```

| EID | EMP_LAST  | MGR_ID | REPORTLEVEL | MGR_LIST    |
|-----|-----------|--------|-------------|-------------|
| 101 | Kochhar   | 100    | 0           | 100         |
| 108 | Greenberg | 101    | 1           | 100,101     |
| 200 | Whalen    | 101    | 1           | 100,101     |
| 203 | Mavris    | 101    | 1           | 100,101     |
| 204 | Baer      | 101    | 1           | 100,101     |
| 205 | Higgins   | 101    | 1           | 100,101     |
| 109 | Faviet    | 108    | 2           | 100,101,108 |
| 110 | Chen      | 108    | 2           | 100,101,108 |
| 111 | Sciarra   | 108    | 2           | 100,101,108 |
| 112 | Urman     | 108    | 2           | 100,101,108 |
| 113 | Popp      | 108    | 2           | 100,101,108 |
| 206 | Gietz     | 205    | 2           | 100,101,205 |

The following statement shows the employees who directly or indirectly report to employee 101 and their reporting level. It stops at reporting level 1.

```

WITH
  reports_to_101 (eid, emp_last, mgr_id, reportLevel) AS
(
  SELECT employee_id, last_name, manager_id, 0 reportLevel
    FROM employees
   WHERE employee_id = 101
UNION ALL
  SELECT e.employee_id, e.last_name, e.manager_id, reportLevel+1
    FROM reports_to_101 r, employees e
   WHERE r.eid = e.manager_id
)
SELECT eid, emp_last, mgr_id, reportLevel
  FROM reports_to_101
 WHERE reportLevel <= 1
 ORDER BY reportLevel, eid;

```

| EID | EMP_LAST  | MGR_ID | REPORTLEVEL |
|-----|-----------|--------|-------------|

The following statement counts the number of employees under each manager.

```
WITH
  emp_count (eid, emp_last, mgr_id, mgrLevel, salary, cnt_employees) AS
  (
    SELECT employee_id, last_name, manager_id, 0 mgrLevel, salary, 0 cnt_employees
    FROM employees
  UNION ALL
    SELECT e.employee_id, e.last_name, e.manager_id,
           r.mgrLevel+1 mgrLevel, e.salary, 1 cnt_employees
    FROM emp_count r, employees e
    WHERE e.employee_id = r.mgr_id
  )
  SEARCH DEPTH FIRST BY emp_last SET order1
SELECT emp_last, eid, mgr_id, salary, sum(cnt_employees), max(mgrLevel) mgrLevel
FROM emp_count
GROUP BY emp_last, eid, mgr_id, salary
HAVING max(mgrLevel) > 0
ORDER BY mgr_id NULLS FIRST, emp_last;
```

| EMP_LAST  | EID | MGR_ID | SALARY | SUM(CNT_EMPLOYEES) | MGRLEVEL |
|-----------|-----|--------|--------|--------------------|----------|

### Analytic Views: Examples

The following statement uses the persistent analytic view sales\_av. The query selects the member\_name hierarchical attribute of time\_hier, which is the alias of a hierarchy of the same name, and values from the sales and units measures of the analytic view that are dimensioned by the time attribute dimension used by the time\_hier hierarchy.. The results of the selection are filtered to those for the YEAR level of the hierarchy. The results are returned in hierarchical order.

```
SELECT time_hier.member_name as TIME,
       sales,
       units
  FROM
    sales_av HIERARCHIES(time_hier)
```

```
WHERE time_hier.level_name = 'YEAR'
ORDER BY time_hier.hier_order;
```

The results of the query are the following:

| TIME   | SALES         | UNITS    |
|--------|---------------|----------|
| CY2011 | 6755115980.73 | 24462444 |
| CY2012 | 6901682398.95 | 24400619 |
| CY2013 | 7240938717.57 | 24407259 |
| CY2014 | 7579746352.89 | 24402666 |
| CY2015 | 7941102885.15 | 24475206 |

### Transitory Analytic View Examples

The following statement defines the transitory analytic view `my_av` in the `WITH` clause. The transitory analytic view is based on the persistent analytic view `sales_av`. The `lag_sales` calculated measure is a `LAG` calculation that is used at query time.

```
WITH
my_av ANALYTIC VIEW AS (
    USING sales_av HIERARCHIES (time_hier)
    ADD MEASURES (
        lag_sales AS (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1))
    )
)
SELECT time_hier.member_name time, sales, lag_sales
FROM my_av HIERARCHIES (time_hier)
WHERE time_hier.level_name = 'YEAR'
ORDER BY time_hier.hier_order;
```

The results of the query are the following:

| TIME   | SALES      | LAG_SALES  |
|--------|------------|------------|
| CY2011 | 6755115981 | (null)     |
| CY2012 | 6901682399 | 6755115981 |
| CY2013 | 7240938718 | 6901682399 |
| CY2014 | 7579746353 | 7240938718 |
| CY2015 | 7941102885 | 7579746353 |

The following statement defines a transitory analytic view that uses a filter clause.

```
WITH
my_av ANALYTIC VIEW AS (
    USING sales_av HIERARCHIES (time_hier)
    FILTER FACT (
        time_hier TO quarter_of_year IN (1, 2)
        AND year_name IN ('CY2011', 'CY2012')
    )
)
SELECT time_hier.member_name time, sales
FROM my_av HIERARCHIES (time_hier)
```

```
WHERE time_hier.level_name IN ('YEAR', 'QUARTER')
ORDER BY time_hier.hier_order;
```

The results of the query are the following:

| TIME     | SALES      |
|----------|------------|
| CY2011   | 3340459835 |
| Q1CY2011 | 1625299627 |
| Q2CY2011 | 1715160208 |
| CY2012   | 3397271965 |
| Q1CY2012 | 1644857783 |
| Q2CY2012 | 1752414182 |

### Inline Analytic View Example

The following statement defines an inline analytic view in the `FROM` clause. The transitory analytic view is based on the persistent analytic view `sales_av`. The `lag_sales` calculated measure is a `LAG` calculation that is used at query time.

```
SELECT time_hier.member_name time, sales, lag_sales
FROM
  ANALYTIC VIEW (
    USING sales_av HIERARCHIES (time_hier)
    ADD MEASURES (
      lag_sales AS (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1))
    )
  )
WHERE time_hier.level_name = 'YEAR'
ORDER BY time_hier.hier_order;
```

The results of the query are the following:

| TIME   | SALES      | LAG_SALES  |
|--------|------------|------------|
| CY2011 | 6755115981 | (null)     |
| CY2012 | 6901682399 | 6755115981 |
| CY2013 | 7240938718 | 6901682399 |
| CY2014 | 7579746353 | 7240938718 |
| CY2015 | 7941102885 | 7579746353 |

### Simple Query Examples

The following statement selects rows from the `employees` table with the department number of 30:

```
SELECT *
  FROM employees
 WHERE department_id = 30
 ORDER BY last_name;
```

The following statement selects the name, job, salary and department number of all employees except purchasing clerks from department number 30:

```
SELECT last_name, job_id, salary, department_id
  FROM employees
 WHERE NOT (job_id = 'PU_CLERK' AND department_id = 30)
 ORDER BY last_name;
```

The following statement selects from subqueries in the `FROM` clause and for each department returns the total employees and salaries as a decimal value of all the departments:

```
SELECT a.department_id "Department",
       a.num_emp/b.total_count "%_Employees",
       a.sal_sum/b.total_sal "%_Salary"
  FROM
    (SELECT department_id, COUNT(*) num_emp, SUM(salary) sal_sum
       FROM employees
      GROUP BY department_id) a,
    (SELECT COUNT(*) total_count, SUM(salary) total_sal
       FROM employees) b
  ORDER BY a.department_id;
```

### Selecting from a Partition: Example

You can select rows from a single partition of a partitioned table by specifying the keyword `PARTITION` in the `FROM` clause. This SQL statement assigns an alias for and retrieves rows from the `sales_q2_2000` partition of the sample table `sh.sales`:

```
SELECT * FROM sales PARTITION (sales_q2_2000) s
  WHERE s.amount_sold > 1500
  ORDER BY cust_id, time_id, channel_id;
```

The following example selects rows from the `oe.orders` table for orders earlier than a specified date:

```
SELECT * FROM orders
  WHERE order_date < TO_DATE('2006-06-15', 'YYYY-MM-DD');
```

### Selecting a Sample: Examples

The following query estimates the number of orders in the `oe.orders` table:

```
SELECT COUNT(*) * 10 FROM orders SAMPLE (10);
-----  
COUNT(*)*10  
-----  
70
```

Because the query returns an estimate, the actual return value may differ from one query to the next.

```
SELECT COUNT(*) * 10 FROM orders SAMPLE (10);
-----  
COUNT(*)*10  
-----  
80
```

The following query adds a seed value to the preceding query. Oracle Database always returns the same estimate given the same seed value:

```
SELECT COUNT(*) * 10 FROM orders SAMPLE(10) SEED (1);
-----  
COUNT(*)*10
```

```
-----  
130  
  
SELECT COUNT(*) * 10 FROM orders SAMPLE(10) SEED(4);  
  
COUNT(*)*10  
-----  
120  
  
SELECT COUNT(*) * 10 FROM orders SAMPLE(10) SEED (1);  
  
COUNT(*)*10  
-----  
130
```

### Using Flashback Queries: Example

The following statements show a current value from the sample table `hr.employees` and then change the value. The intervals used in these examples are very short for demonstration purposes. Time intervals in your own environment are likely to be larger.

```
SELECT salary FROM employees  
WHERE last_name = 'Chung';  
  
SALARY  
-----  
3800  
  
UPDATE employees SET salary = 4000  
WHERE last_name = 'Chung';  
1 row updated.  
  
SELECT salary FROM employees  
WHERE last_name = 'Chung';  
  
SALARY  
-----  
4000
```

To learn what the value was before the update, you can use the following Flashback Query:

```
SELECT salary FROM employees  
AS OF TIMESTAMP (SYSTIMESTAMP - INTERVAL '1' MINUTE)  
WHERE last_name = 'Chung';  
  
SALARY  
-----  
3800
```

To learn what the values were during a particular time period, you can use a version Flashback Query:

```
SELECT salary FROM employees  
VERSIONS BETWEEN TIMESTAMP  
SYSTIMESTAMP - INTERVAL '10' MINUTE AND  
SYSTIMESTAMP - INTERVAL '1' MINUTE  
WHERE last_name = 'Chung';
```

To revert to the earlier value, use the Flashback Query as the subquery of another `UPDATE` statement:

```
UPDATE employees SET salary =
  (SELECT salary FROM employees
   AS OF TIMESTAMP (SYSTIMESTAMP - INTERVAL '2' MINUTE)
   WHERE last_name = 'Chung')
   WHERE last_name = 'Chung';
1 row updated.

SELECT salary FROM employees
  WHERE last_name = 'Chung';

  SALARY
-----
  3800
```

### Using the GROUP BY Clause: Examples

To return the minimum and maximum salaries for each department in the employees table, issue the following statement:

```
SELECT department_id, MIN(salary), MAX (salary)
  FROM employees
 GROUP BY department_id
 ORDER BY department_id;
```

To return the minimum and maximum salaries for the clerks in each department, issue the following statement:

```
SELECT department_id, MIN(salary), MAX (salary)
  FROM employees
 WHERE job_id = 'PU_CLERK'
 GROUP BY department_id
 ORDER BY department_id;
```

The following example counts how many employees were hired each year. The GROUP BY clause uses the column alias YEAR\_HIRED, so this groups using the expression TRUNC(hire\_date, 'YYYY')

```
SELECT TRUNC(hire_date, 'YYYY') year_hired, COUNT(*)
  FROM employees
 GROUP BY year_hired
 ORDER BY year_hired;

YEAR_HIRED COUNT(*)
-----
01-JAN-2011 1
01-JAN-2012 7
...
01-JAN-2017 19
01-JAN-2018 11
```

The following example counts how many employees were hired each day. The query groups by HIRE\_DATE, which is the name of a column in EMPLOYEES and a SELECT list alias. The column name takes priority, so the query groups by the column, not the alias.

```
SELECT TRUNC(hire_date, 'YYYY') hire_date, COUNT(*)
  FROM employees
 GROUP BY hire_date
 ORDER BY hire_date;
```

```

HIRE_DATE COUNT(*)
-----
01-JAN-2011 1
01-JAN-2012 4
01-JAN-2012 1
...
01-JAN-2018 1
01-JAN-2018 1

```

### Using the GROUP BY CUBE Clause: Example

To return the number of employees and their average yearly salary across all possible combinations of department and job category, issue the following query on the sample tables `hr.employees` and `hr.departments`:

```

SELECT DECODE(GROUPING(department_name), 1, 'All Departments',
               department_name) AS department_name,
       DECODE(GROUPING(job_id), 1, 'All Jobs', job_id) AS job_id,
       COUNT(*) "Total Empl", AVG(salary) * 12 "Average Sal"
  FROM employees e, departments d
 WHERE d.department_id = e.department_id
 GROUP BY CUBE (department_name, job_id)
 ORDER BY department_name, job_id;

```

| DEPARTMENT_NAME | JOB_ID     | Total Empl | Average Sal |
|-----------------|------------|------------|-------------|
| Accounting      | AC_ACCOUNT | 1          | 99600       |
| Accounting      | AC_MGR     | 1          | 144000      |
| Accounting      | All Jobs   | 2          | 121800      |
| Administration  | AD_ASST    | 1          | 52800       |
| ...             |            |            |             |
| Shipping        | ST_CLERK   | 20         | 33420       |
| Shipping        | ST_MAN     | 5          | 87360       |

### Using the GROUPING SETS Clause: Example

The following example finds the sum of sales aggregated for three precisely specified groups:

- (`channel_desc, calendar_month_desc, country_id`)
- (`channel_desc, country_id`)
- (`calendar_month_desc, country_id`)

Without the GROUPING SETS syntax, you would have to write less efficient queries with more complicated SQL. For example, you could run three separate queries and `UNION` them, or run a query with a `CUBE(channel_desc, calendar_month_desc, country_id)` operation and filter out five of the eight groups it would generate.

```

SELECT channel_desc, calendar_month_desc, co.country_id,
       TO_CHAR(sum(amount_sold), '9,999,999,999') SALES$
  FROM sales, customers, times, channels, countries co
 WHERE sales.time_id=times.time_id
       AND sales.cust_id=customers.cust_id
       AND sales.channel_id=channels.channel_id
       AND customers.country_id = co.country_id
       AND channels.channel_desc IN ('Direct Sales', 'Internet')
       AND times.calendar_month_desc IN ('2000-09', '2000-10')
       AND co.country_iso_code IN ('UK', 'US')
 GROUP BY GROUPING SETS(
       (channel_desc, calendar_month_desc, co.country_id),

```

```
(channel_desc, co.country_id),
(calendar_month_desc, co.country_id) );
```

| CHANNEL_DESC | CALENDAR_MONTH_DESC | COUNTRY_ID | SALES\$   |
|--------------|---------------------|------------|-----------|
| Internet     | 2000-09             | 52790      | 124,224   |
| Direct Sales | 2000-09             | 52790      | 638,201   |
| Internet     | 2000-10             | 52790      | 137,054   |
| Direct Sales | 2000-10             | 52790      | 682,297   |
|              | 2000-09             | 52790      | 762,425   |
|              | 2000-10             | 52790      | 819,351   |
| Internet     |                     | 52790      | 261,278   |
| Direct Sales |                     | 52790      | 1,320,497 |

The functions [GROUP\\_ID](#), [GROUPING](#), and [GROUPING\\_ID](#) for more information on those functions

## Hierarchical Query: Examples

The following query with a CONNECT BY clause defines a hierarchical relationship in which the `employee_id` value of the parent row is equal to the `manager_id` value of the child row:

```
SELECT last_name, employee_id, manager_id FROM employees
  CONNECT BY employee_id = manager_id
  ORDER BY last_name;
```

In the following CONNECT BY clause, the PRIOR operator applies only to the `employee_id` value. To evaluate this condition, the database evaluates `employee_id` values for the parent row and `manager_id`, `salary`, and `commission_pct` values for the child row:

```
SELECT last_name, employee_id, manager_id FROM employees
  CONNECT BY PRIOR employee_id = manager_id
  AND salary > commission_pct
  ORDER BY last_name;
```

To qualify as a child row, a row must have a `manager_id` value equal to the `employee_id` value of the parent row and it must have a `salary` value greater than its `commission_pct` value.

## Using the HAVING Condition: Example

To return the minimum and maximum salaries for the employees in each department whose lowest salary is less than \$5,000, issue the next statement:

```
SELECT department_id, MIN(salary), MAX(salary)
  FROM employees
 GROUP BY department_id
 HAVING MIN(salary) < 5000
 ORDER BY department_id;
```

| DEPARTMENT_ID | MIN(SALARY) | MAX(SALARY) |
|---------------|-------------|-------------|
| 10            | 4400        | 4400        |
| 30            | 2500        | 11000       |

|    |      |      |
|----|------|------|
| 50 | 2100 | 8200 |
| 60 | 4200 | 9000 |

The following example uses a correlated subquery in a HAVING clause that eliminates from the result set any departments without managers and managers without departments:

```
SELECT department_id, manager_id
  FROM employees
 GROUP BY department_id, manager_id HAVING (department_id, manager_id) IN
 (SELECT department_id, manager_id FROM employees x
   WHERE x.department_id = employees.department_id)
 ORDER BY department_id;
```

### Using the ORDER BY Clause: Examples

To select all purchasing clerk records from `employees` and order the results by salary in descending order, issue the following statement:

```
SELECT *
  FROM employees
 WHERE job_id = 'PU_CLERK'
 ORDER BY salary DESC;
```

To select information from `employees` ordered first by ascending department number and then by descending salary, issue the following statement:

```
SELECT last_name, department_id, salary
  FROM employees
 ORDER BY department_id ASC, salary DESC, last_name;
```

To select the same information as the previous SELECT and use the positional ORDER BY notation, issue the following statement, which orders by ascending `department_id`, then descending `salary`, and finally alphabetically by `last_name`:

```
SELECT last_name, department_id, salary
  FROM employees
 ORDER BY 2 ASC, 3 DESC, 1;
```

### The MODEL clause: Examples

The view created below is based on the sample `sh` schema and is used by the example that follows.

```
CREATE OR REPLACE VIEW sales_view_ref AS
  SELECT country_name country,
         prod_name prod,
         calendar_year year,
         SUM(amount_sold) sale,
         COUNT(amount_sold) cnt
    FROM sales,times,customers,countries,products
   WHERE sales.time_id = times.time_id
     AND sales.prod_id = products.prod_id
     AND sales.cust_id = customers.cust_id
     AND customers.country_id = countries.country_id
     AND ( customers.country_id = 52779
           OR customers.country_id = 52776 )
     AND ( prod_name = 'Standard Mouse'
           OR prod_name = 'Mouse Pad' )
  GROUP BY country_name,prod_name,calendar_year;

  SELECT country, prod, year, sale
```

```
FROM sales_view_ref
ORDER BY country, prod, year;
```

| COUNTRY | PROD           | YEAR | SALE    |
|---------|----------------|------|---------|
| France  | Mouse Pad      | 1998 | 2509.42 |
| France  | Mouse Pad      | 1999 | 3678.69 |
| France  | Mouse Pad      | 2000 | 3000.72 |
| France  | Mouse Pad      | 2001 | 3269.09 |
| France  | Standard Mouse | 1998 | 2390.83 |
| France  | Standard Mouse | 1999 | 2280.45 |
| France  | Standard Mouse | 2000 | 1274.31 |
| France  | Standard Mouse | 2001 | 2164.54 |
| Germany | Mouse Pad      | 1998 | 5827.87 |
| Germany | Mouse Pad      | 1999 | 8346.44 |
| Germany | Mouse Pad      | 2000 | 7375.46 |
| Germany | Mouse Pad      | 2001 | 9535.08 |
| Germany | Standard Mouse | 1998 | 7116.11 |
| Germany | Standard Mouse | 1999 | 6263.14 |
| Germany | Standard Mouse | 2000 | 2637.31 |
| Germany | Standard Mouse | 2001 | 6456.13 |

16 rows selected.

The next example creates a multidimensional array from `sales_view_ref` with columns containing country, product, year, and sales. It also:

- Assigns the sum of the sales of the Mouse Pad for years 1999 and 2000 to the sales of the Mouse Pad for year 2001, if a row containing sales of the Mouse Pad for year 2001 exists.
- Assigns the value of sales of the Standard Mouse for year 2001 to sales of the Standard Mouse for year 2002, creating a new row if a row containing sales of the Standard Mouse for year 2002 does not exist.

```
SELECT country,prod,year,s
  FROM sales_view_ref
  MODEL
    PARTITION BY (country)
    DIMENSION BY (prod, year)
    MEASURES (sale s)
    IGNORE NAV
    UNIQUE DIMENSION
    RULES UPSERT SEQUENTIAL ORDER
    (
      s[prod='Mouse Pad', year=2001] =
        s['Mouse Pad', 1999] + s['Mouse Pad', 2000],
      s['Standard Mouse', 2002] = s['Standard Mouse', 2001]
    )
  ORDER BY country, prod, year;
```

| COUNTRY | PROD           | YEAR | SALE    |
|---------|----------------|------|---------|
| France  | Mouse Pad      | 1998 | 2509.42 |
| France  | Mouse Pad      | 1999 | 3678.69 |
| France  | Mouse Pad      | 2000 | 3000.72 |
| France  | Mouse Pad      | 2001 | 6679.41 |
| France  | Standard Mouse | 1998 | 2390.83 |
| France  | Standard Mouse | 1999 | 2280.45 |
| France  | Standard Mouse | 2000 | 1274.31 |
| France  | Standard Mouse | 2001 | 2164.54 |

|         |                |      |         |
|---------|----------------|------|---------|
| France  | Standard Mouse | 2002 | 2164.54 |
| Germany | Mouse Pad      | 1998 | 5827.87 |
| Germany | Mouse Pad      | 1999 | 8346.44 |
| Germany | Mouse Pad      | 2000 | 7375.46 |
| Germany | Mouse Pad      | 2001 | 15721.9 |
| Germany | Standard Mouse | 1998 | 7116.11 |
| Germany | Standard Mouse | 1999 | 6263.14 |
| Germany | Standard Mouse | 2000 | 2637.31 |
| Germany | Standard Mouse | 2001 | 6456.13 |
| Germany | Standard Mouse | 2002 | 6456.13 |

18 rows selected.

The first rule uses UPDATE behavior because symbolic referencing is used on the left-hand side of the rule. The rows represented by the left-hand side of the rule exist, so the measure columns are updated. If the rows did not exist, then no action would have been taken.

The second rule uses UPSERT behavior because positional referencing is used on the left-hand side and a single cell is referenced. The rows do not exist, so new rows are inserted and the related measure columns are updated. If the rows did exist, then the measure columns would have been updated.

### See Also:

*Oracle Database Data Warehousing Guide* for an expanded discussion and examples

The next example uses the same `sales_view_ref` view and the analytic function `SUM` to calculate a cumulative sum (`csum`) of sales per country and per year.

```
SELECT country, year, sale, csum
  FROM
    (SELECT country, year, SUM(sale) sale
      FROM sales_view_ref
     GROUP BY country, year
    )
  MODEL DIMENSION BY (country, year)
    MEASURES (sale, 0 csum)
    RULES (csum[any, any]=
              SUM(sale) OVER (PARTITION BY country
                               ORDER BY year
                               ROWS UNBOUNDED PRECEDING)
            )
  ORDER BY country, year;
```

| COUNTRY | YEAR | SALE     | CSUM     |
|---------|------|----------|----------|
| France  | 1998 | 4900.25  | 4900.25  |
| France  | 1999 | 5959.14  | 10859.39 |
| France  | 2000 | 4275.03  | 15134.42 |
| France  | 2001 | 5433.63  | 20568.05 |
| Germany | 1998 | 12943.98 | 12943.98 |
| Germany | 1999 | 14609.58 | 27553.56 |
| Germany | 2000 | 10012.77 | 37566.33 |
| Germany | 2001 | 15991.21 | 53557.54 |

8 rows selected.

### Row Limiting: Examples

The following statement returns the 5 employees with the lowest `employee_id` values:

```
SELECT employee_id, last_name
  FROM employees
 ORDER BY employee_id
  FETCH FIRST 5 ROWS ONLY;
```

| EMPLOYEE_ID | LAST_NAME |
|-------------|-----------|
| 100         | King      |
| 101         | Kochhar   |
| 102         | De Haan   |
| 103         | Hunold    |
| 104         | Ernst     |

The following statement returns the next 5 employees with the lowest `employee_id` values:

```
SELECT employee_id, last_name
  FROM employees
 ORDER BY employee_id
  OFFSET 5 ROWS FETCH NEXT 5 ROWS ONLY;
```

| EMPLOYEE_ID | LAST_NAME |
|-------------|-----------|
| 105         | Austin    |
| 106         | Pataballa |
| 107         | Lorentz   |
| 108         | Greenberg |
| 109         | Faviet    |

The following statement returns the 5 percent of employees with the lowest salaries:

```
SELECT employee_id, last_name, salary
  FROM employees
 ORDER BY salary
  FETCH FIRST 5 PERCENT ROWS ONLY;
```

| EMPLOYEE_ID | LAST_NAME  | SALARY |
|-------------|------------|--------|
| 132         | Olson      | 2100   |
| 128         | Markle     | 2200   |
| 136         | Philtanker | 2200   |
| 127         | Landry     | 2400   |
| 135         | Gee        | 2400   |
| 119         | Colmenares | 2500   |

Because `WITH TIES` is specified, the following statement returns the 5 percent of employees with the lowest salaries, plus all additional employees with the same salary as the last row fetched in the previous example:

```
SELECT employee_id, last_name, salary
  FROM employees
 ORDER BY salary
  FETCH FIRST 5 PERCENT ROWS WITH TIES;
```

| EMPLOYEE_ID | LAST_NAME | SALARY |
|-------------|-----------|--------|
| 132         | Olson     | 2100   |

|     |            |      |
|-----|------------|------|
| 128 | Markle     | 2200 |
| 136 | Philtanker | 2200 |
| 127 | Landry     | 2400 |
| 135 | Gee        | 2400 |
| 119 | Colmenares | 2500 |
| 131 | Marlow     | 2500 |
| 140 | Patel      | 2500 |
| 144 | Vargas     | 2500 |
| 182 | Sullivan   | 2500 |
| 191 | Perkins    | 2500 |

### Using the FOR UPDATE Clause: Examples

The following statement locks rows in the `employees` table with purchasing clerks located in Oxford, which has `location_id` 2500, and locks rows in the `departments` table with departments in Oxford that have purchasing clerks:

```
SELECT e.employee_id, e.salary, e.commission_pct
  FROM employees e, departments d
 WHERE job_id = 'SA_REP'
   AND e.department_id = d.department_id
   AND location_id = 2500
 ORDER BY e.employee_id
FOR UPDATE;
```

The following statement locks only those rows in the `employees` table with purchasing clerks located in Oxford. No rows are locked in the `departments` table:

```
SELECT e.employee_id, e.salary, e.commission_pct
  FROM employees e JOIN departments d
    USING (department_id)
 WHERE job_id = 'SA_REP'
   AND location_id = 2500
 ORDER BY e.employee_id
FOR UPDATE OF e.salary;
```

### Using the WITH CHECK OPTION Clause: Example

The following statement is legal even though the third value inserted violates the condition of the subquery `where_clause`:

```
INSERT INTO (SELECT department_id, department_name, location_id
  FROM departments WHERE location_id < 2000)
VALUES (9999, 'Entertainment', 2500);
```

However, the following statement is illegal because it contains the `WITH CHECK OPTION` clause:

```
INSERT INTO (SELECT department_id, department_name, location_id
  FROM departments WHERE location_id < 2000 WITH CHECK OPTION)
VALUES (9999, 'Entertainment', 2500);
*
ERROR at line 2:
ORA-01402: view WITH CHECK OPTION where-clause violation
```

### Using PIVOT and UNPIVOT: Examples

The `oe.orders` table contains information about when an order was placed (`order_date`), how it was place (`order_mode`), and the total amount of the order (`order_total`), as well as other information. The following example shows how to use the `PIVOT` clause to pivot `order_mode` values into columns, aggregating `order_total` data in the process, to get yearly totals by order mode:

```
CREATE TABLE pivot_table AS
SELECT * FROM
(SELECT EXTRACT(YEAR FROM order_date) year, order_mode, order_total FROM orders)
PIVOT
(SUM(order_total) FOR order_mode IN ('direct' AS Store, 'online' AS Internet));

SELECT * FROM pivot_table ORDER BY year;

YEAR      STORE     INTERNET
-----
2004      5546.6
2006    371895.5   100056.6
2007   1274078.8   1271019.5
2008   252108.3    393349.4
```

The UNPIVOT clause lets you rotate specified columns so that the input column headings are output as values of one or more descriptor columns, and the input column values are output as values of one or more measures columns. The first query that follows shows that nulls are excluded by default. The second query shows that you can include nulls using the INCLUDE NULLS clause.

```
SELECT * FROM pivot_table
UNPIVOT (yearly_total FOR order_mode IN (store AS 'direct',
   internet AS 'online'))
ORDER BY year, order_mode;

YEAR ORDER_  YEARLY_TOTAL
-----
2004 direct      5546.6
2006 direct      371895.5
2006 online      100056.6
2007 direct      1274078.8
2007 online      1271019.5
2008 direct      252108.3
2008 online      393349.4

7 rows selected.

SELECT * FROM pivot_table
UNPIVOT INCLUDE NULLS
(yearly_total FOR order_mode IN (store AS 'direct', internet AS 'online'))
ORDER BY year, order_mode;

YEAR ORDER_  YEARLY_TOTAL
-----
2004 direct      5546.6
2004 online      0.0
2006 direct      371895.5
2006 online      100056.6
2007 direct      1274078.8
2007 online      1271019.5
2008 direct      252108.3
2008 online      393349.4

8 rows selected.
```

### Using Join Queries: Examples

The following examples show various ways of joining tables in a query. In the first example, an equijoin returns the name and job of each employee and the number and name of the department in which the employee works:

```
SELECT last_name, job_id, departments.department_id, department_name
  FROM employees, departments
 WHERE employees.department_id = departments.department_id
 ORDER BY last_name, job_id;
```

| LAST_NAME | JOB_ID   | DEPARTMENT_ID | DEPARTMENT_NAME |
|-----------|----------|---------------|-----------------|
| Abel      | SA_REP   | 80            | Sales           |
| Ande      | SA_REP   | 80            | Sales           |
| Atkinson  | ST_CLERK | 50            | Shipping        |
| Austin    | IT_PROG  | 60            | IT              |
| ...       |          |               |                 |

You must use a join to return this data because employee names and jobs are stored in a different table than department names. Oracle Database combines rows of the two tables according to this join condition:

```
employees.department_id = departments.department_id
```

The following equijoin returns the name, job, department number, and department name of all sales managers:

```
SELECT last_name, job_id, departments.department_id, department_name
  FROM employees, departments
 WHERE employees.department_id = departments.department_id
   AND job_id = 'SA_MAN'
 ORDER BY last_name;
```

| LAST_NAME | JOB_ID | DEPARTMENT_ID | DEPARTMENT_NAME |
|-----------|--------|---------------|-----------------|
| Cambrault | SA_MAN | 80            | Sales           |
| Errazuriz | SA_MAN | 80            | Sales           |
| Partners  | SA_MAN | 80            | Sales           |
| Russell   | SA_MAN | 80            | Sales           |
| Zlotkey   | SA_MAN | 80            | Sales           |

This query is identical to the preceding example, except that it uses an additional *where\_clause* condition to return only rows with a job value of 'SA\_MAN'.

### Using Subqueries: Examples

To determine who works in the same department as employee 'Lorentz', issue the following statement:

```
SELECT last_name, department_id FROM employees
 WHERE department_id =
 (SELECT department_id FROM employees
  WHERE last_name = 'Lorentz')
 ORDER BY last_name, department_id;
```

To give all employees in the employees table a 10% raise if they have changed jobs—if they appear in the job\_history table—issue the following statement:

```
UPDATE employees
 SET salary = salary * 1.1
 WHERE employee_id IN (SELECT employee_id FROM job_history);
```

To create a second version of the departments table new\_departments, with only three of the columns of the original table, issue the following statement:

```
CREATE TABLE new_departments
  (department_id, department_name, location_id)
AS SELECT department_id, department_name, location_id
FROM departments;
```

### Using Self Joins: Example

The following query uses a self join to return the name of each employee along with the name of the employee's manager. A WHERE clause is added to shorten the output.

```
SELECT e1.last_name||' works for '||e2.last_name
  "Employees and Their Managers"
  FROM employees e1, employees e2
 WHERE e1.manager_id = e2.employee_id
   AND e1.last_name LIKE 'R%'
 ORDER BY e1.last_name;
```

Employees and Their Managers

```
-----  
Rajs works for Mourgos  
Raphaelly works for King  
Rogers works for Kaufling  
Russell works for King
```

The join condition for this query uses the aliases e1 and e2 for the sample table employees:

```
e1.manager_id = e2.employee_id
```

### Using Outer Joins: Examples

The following example shows how a partitioned outer join fills data gaps in rows to facilitate analytic function specification and reliable report formatting. The example first creates a small data table to be used in the join:

```
SELECT d.department_id, e.last_name
  FROM departments d LEFT OUTER JOIN employees e
    ON d.department_id = e.department_id
 ORDER BY d.department_id, e.last_name;
```

Users familiar with the traditional Oracle Database outer joins syntax will recognize the same query in this form:

```
SELECT d.department_id, e.last_name
  FROM departments d, employees e
 WHERE d.department_id = e.department_id(+)
 ORDER BY d.department_id, e.last_name;
```

Oracle strongly recommends that you use the more flexible FROM clause join syntax shown in the former example.

The left outer join returns all departments, including those without any employees. The same statement with a right outer join returns all employees, including those not yet assigned to a department:

 Note:

The employee Zeuss was added to the employees table for these examples, and is not part of the sample data.

```
SELECT d.department_id, e.last_name
  FROM departments d RIGHT OUTER JOIN employees e
    ON d.department_id = e.department_id
   ORDER BY d.department_id, e.last_name;
```

| DEPARTMENT_ID | LAST_NAME |
|---------------|-----------|
| 110           | Gietz     |
| 110           | Higgins   |
|               | Grant     |
|               | Zeuss     |

It is not clear from this result whether employees Grant and Zeuss have department\_id NULL, or whether their department\_id is not in the departments table. To determine this requires a full outer join:

```
SELECT d.department_id as d_dept_id, e.department_id as e_dept_id,
       e.last_name
  FROM departments d FULL OUTER JOIN employees e
    ON d.department_id = e.department_id
   ORDER BY d.department_id, e.last_name;
```

| D_DEPT_ID | E_DEPT_ID | LAST_NAME |
|-----------|-----------|-----------|
| 110       | 110       | Gietz     |
| 110       | 110       | Higgins   |
| ..        |           |           |
| 260       |           |           |
| 270       |           |           |
|           | 999       | Zeuss     |
|           |           | Grant     |

Because the column names in this example are the same in both tables in the join, you can also use the common column feature by specifying the USING clause of the join syntax. The output is the same as for the preceding example except that the USING clause coalesces the two matching columns department\_id into a single column output:

```
SELECT department_id AS d_e_dept_id, e.last_name
  FROM departments d FULL OUTER JOIN employees e
    USING (department_id)
   ORDER BY department_id, e.last_name;
```

| D_E_DEPT_ID | LAST_NAME |
|-------------|-----------|
| 110         | Higgins   |
| 110         | Gietz     |
| ..          |           |
| 260         |           |
| 270         |           |

```
999 Zeuss
Grant
```

### Using Partitioned Outer Joins: Examples

The following example shows how a partitioned outer join fills in gaps in rows to facilitate analytic calculation specification and reliable report formatting. The example first creates and populates a simple table to be used in the join:

```
CREATE TABLE inventory (time_id      DATE,
                      product       VARCHAR2(10),
                      quantity      NUMBER);

INSERT INTO inventory VALUES (TO_DATE('01/04/01', 'DD/MM/YY'), 'bottle', 10);
INSERT INTO inventory VALUES (TO_DATE('06/04/01', 'DD/MM/YY'), 'bottle', 10);
INSERT INTO inventory VALUES (TO_DATE('01/04/01', 'DD/MM/YY'), 'can', 10);
INSERT INTO inventory VALUES (TO_DATE('04/04/01', 'DD/MM/YY'), 'can', 10);

SELECT times.time_id, product, quantity FROM inventory
PARTITION BY (product)
RIGHT OUTER JOIN times ON (times.time_id = inventory.time_id)
WHERE times.time_id BETWEEN TO_DATE('01/04/01', 'DD/MM/YY')
AND TO_DATE('06/04/01', 'DD/MM/YY')
ORDER BY 2,1;

TIME_ID      PRODUCT      QUANTITY
----- -----
01-APR-01    bottle        10
02-APR-01    bottle
03-APR-01    bottle
04-APR-01    bottle
05-APR-01    bottle
06-APR-01    bottle        10
01-APR-01    can           10
02-APR-01    can
03-APR-01    can
04-APR-01    can           10
05-APR-01    can
06-APR-01    can

12 rows selected.
```

The data is now more dense along the time dimension for each partition of the product dimension. However, each of the newly added rows within each partition is null in the quantity column. It is more useful to see the nulls replaced by the preceding non-NULL value in time order. You can achieve this by applying the analytic function `LAST_VALUE` on top of the query result:

```
SELECT time_id, product, LAST_VALUE(quantity IGNORE NULLS)
OVER (PARTITION BY product ORDER BY time_id) quantity
FROM ( SELECT times.time_id, product, quantity
      FROM inventory PARTITION BY (product)
      RIGHT OUTER JOIN times ON (times.time_id = inventory.time_id)
      WHERE times.time_id BETWEEN TO_DATE('01/04/01', 'DD/MM/YY')
      AND TO_DATE('06/04/01', 'DD/MM/YY'))
      ORDER BY 2,1;

TIME_ID      PRODUCT      QUANTITY
----- -----
01-APR-01    bottle        10

*Oracle Database Data Warehousing Guide* for an expanded discussion on filling gaps in time series calculations and examples of usage

## Using Antijoins: Example

The following example selects a list of employees who are not in a particular set of departments:

```

SELECT * FROM employees
  WHERE department_id NOT IN
    (SELECT department_id FROM departments
     WHERE location_id = 1700)
  ORDER BY last_name;

```

## Using Semijoins: Example

In the following example, only one row needs to be returned from the `departments` table, even though many rows in the `employees` table might match the subquery. If no index has been defined on the `salary` column in `employees`, then a semijoin can be used to improve query performance.

```

SELECT * FROM departments
 WHERE EXISTS
   (SELECT * FROM employees
    WHERE departments.department_id = employees.department_id
      AND employees.salary > 2500)
  ORDER BY department_name;

```

## Using CROSS APPLY and OUTER APPLY Joins: Examples

The following statement uses the `CROSS APPLY` clause of the `cross_outer_apply_clause`. The join returns only rows from the table on the left side of the join (`departments`) that produce a result from the inline view on the right side of the join. That is, the join returns only the departments that have at least one employee. The `WHERE` clause restricts the result set to include only the Marketing, Operations, and Public Relations departments. However, the Operations department is not included in the result set because it has no employees.

```

SELECT d.department_name, v.employee_id, v.last_name
  FROM departments d CROSS APPLY (SELECT * FROM employees e
                                     WHERE e.department_id = d.department_id) v
 WHERE d.department_name IN ('Marketing', 'Operations', 'Public Relations')
  ORDER BY d.department_name, v.employee_id;

```

| DEPARTMENT_NAME  | EMPLOYEE_ID | LAST_NAME |
|------------------|-------------|-----------|
| Marketing        | 201         | Hartstein |
| Marketing        | 202         | Fay       |
| Public Relations | 204         | Baer      |

The following statement uses the `OUTER APPLY` clause of the `cross_outer_apply_clause`. The join returns all rows from the table on the left side of the join (`departments`) regardless of whether they produce a result from the inline view on the right side of the join. That is, the join returns all departments regardless of whether the departments have any employees. The `WHERE` clause restricts the result set to include only the Marketing, Operations, and Public Relations departments. The Operations department is included in the result set even though it has no employees.

```
SELECT d.department_name, v.employee_id, v.last_name
  FROM departments d OUTER APPLY (SELECT * FROM employees e
                                     WHERE e.department_id = d.department_id) v
 WHERE d.department_name IN ('Marketing', 'Operations', 'Public Relations')
 ORDER by d.department_name, v.employee_id;
```

| DEPARTMENT_NAME  | EMPLOYEE_ID | LAST_NAME |
|------------------|-------------|-----------|
| Marketing        | 201         | Hartstein |
| Marketing        | 202         | Fay       |
| Operations       |             |           |
| Public Relations | 204         | Baer      |

### Using Lateral Inline Views: Example

The following example shows a join with two operands. The second operand is an inline view that specifies the first operand, table `e`, in the `WHERE` clause. This results in an error.

```
SELECT * FROM employees e, (SELECT * FROM departments d
                             WHERE e.department_id = d.department_id);
ORA-00904: "E"."DEPARTMENT_ID": invalid identifier
```

The following example shows a join with two operands. The second operand is a lateral inline view that specifies the first operand, table `e`, in the `WHERE` clause and succeeds without an error.

```
SELECT * FROM employees e, LATERAL(SELECT * FROM departments d
                                    WHERE e.department_id = d.department_id);
```

### Table Collections: Examples

You can perform DML operations on nested tables only if they are defined as columns of a table. Therefore, when the `query_table_expr_clause` of an `INSERT`, `DELETE`, or `UPDATE` statement is a `table_collection_expression`, the collection expression must be a subquery that uses the `TABLE` collection expression to select the nested table column of the table. The examples that follow are based on the following scenario:

Suppose the database contains a table `hr_info` with columns `department_id`, `location_id`, and `manager_id`, and a column of nested table type `people` which has `last_name`, `department_id`, and `salary` columns for all the employees of each respective manager:

```

CREATE TYPE people_typ AS OBJECT (
    last_name      VARCHAR2(25),
    department_id  NUMBER(4),
    salary         NUMBER(8,2));
/
CREATE TYPE people_tab_typ AS TABLE OF people_typ;
/
CREATE TABLE hr_info (
    department_id  NUMBER(4),
    location_id   NUMBER(4),
    manager_id    NUMBER(6),
    people        people_tab_typ)
NESTED TABLE people STORE AS people_stor_tab;

INSERT INTO hr_info VALUES (280, 1800, 999, people_tab_typ());

```

The following example inserts into the `people` nested table column of the `hr_info` table for department 280:

```

INSERT INTO TABLE(SELECT h.people FROM hr_info h
                  WHERE h.department_id = 280)
VALUES ('Smith', 280, 1750);

```

The next example updates the department 280 `people` nested table:

```

UPDATE TABLE(SELECT h.people FROM hr_info h
              WHERE h.department_id = 280) p
SET p.salary = p.salary + 100;

```

The next example deletes from the department 280 `people` nested table:

```

DELETE TABLE(SELECT h.people FROM hr_info h
              WHERE h.department_id = 280) p
WHERE p.salary > 1700;

```

### Collection Unnesting: Examples

To select data from a nested table column, use the `TABLE` collection expression to treat the nested table as columns of a table. This process is called **collection unnesting**.

You could get all the rows from `hr_info`, which was created in the preceding example, and all the rows from the `people` nested table column of `hr_info` using the following statement:

```

SELECT t1.department_id, t2.* FROM hr_info t1, TABLE(t1.people) t2
  WHERE t2.department_id = t1.department_id;

```

Now suppose that `people` is not a nested table column of `hr_info`, but is instead a separate table with columns `last_name`, `department_id`, `address`, `hiredate`, and `salary`. You can extract the same rows as in the preceding example with this statement:

```

SELECT t1.department_id, t2.*
  FROM hr_info t1, TABLE(CAST(MULTISET(
    SELECT t3.last_name, t3.department_id, t3.salary
      FROM people t3
     WHERE t3.department_id = t1.department_id)
   AS people_tab_typ)) t2;

```

Finally, suppose that `people` is neither a nested table column of table `hr_info` nor a table itself. Instead, you have created a function `people_func` that extracts from various sources the name, department, and salary of all employees. You can get the same information as in the preceding examples with the following query:

```
SELECT t1.department_id, t2.* FROM hr_info t1, TABLE(CAST
(people_func( ... ) AS people_tab_typ)) t2;
```

 **See Also:**

*Oracle Database Object-Relational Developer's Guide* for more examples of collection unnesting.

### Using the LEVEL Pseudocolumn: Examples

The following statement returns all employees in hierarchical order. The root row is defined to be the employee whose job is AD\_VP. The child rows of a parent row are defined to be those who have the employee number of the parent row as their manager number.

```
SELECT LPAD(' ',2*(LEVEL-1)) || last_name org_chart,
       employee_id, manager_id, job_id
  FROM employees
 START WITH job_id = 'AD_VP'
CONNECT BY PRIOR employee_id = manager_id;
```

| ORG_CHART | EMPLOYEE_ID | MANAGER_ID | JOB_ID     |
|-----------|-------------|------------|------------|
| Kochhar   | 101         | 100        | AD_VP      |
| Greenberg | 108         | 101        | FI_MGR     |
| Faviet    | 109         | 108        | FI_ACCOUNT |
| Chen      | 110         | 108        | FI_ACCOUNT |
| Sciarra   | 111         | 108        | FI_ACCOUNT |
| Urman     | 112         | 108        | FI_ACCOUNT |
| Popp      | 113         | 108        | FI_ACCOUNT |
| Whalen    | 200         | 101        | AD_ASST    |
| Mavris    | 203         | 101        | HR REP     |
| Baer      | 204         | 101        | PR REP     |
| Higgins   | 205         | 101        | AC_MGR     |
| Gietz     | 206         | 205        | AC_ACCOUNT |
| De Haan   | 102         | 100        | AD_VP      |
| Hunold    | 103         | 102        | IT_PROG    |
| Ernst     | 104         | 103        | IT_PROG    |
| Austin    | 105         | 103        | IT_PROG    |
| Pataballa | 106         | 103        | IT_PROG    |
| Lorentz   | 107         | 103        | IT_PROG    |

The following statement is similar to the previous one, except that it does not select employees with the job FI\_MGR.

```
SELECT LPAD(' ',2*(LEVEL-1)) || last_name org_chart,
       employee_id, manager_id, job_id
  FROM employees
 WHERE job_id != 'FI_MGR'
 START WITH job_id = 'AD_VP'
CONNECT BY PRIOR employee_id = manager_id;
```

| ORG_CHART | EMPLOYEE_ID | MANAGER_ID | JOB_ID     |
|-----------|-------------|------------|------------|
| Kochhar   | 101         | 100        | AD_VP      |
| Faviet    | 109         | 108        | FI_ACCOUNT |
| Chen      | 110         | 108        | FI_ACCOUNT |

|           |     |                |
|-----------|-----|----------------|
| Sciarra   | 111 | 108 FI_ACCOUNT |
| Urman     | 112 | 108 FI_ACCOUNT |
| Popp      | 113 | 108 FI_ACCOUNT |
| Whalen    | 200 | 101 AD_ASST    |
| Mavris    | 203 | 101 HR REP     |
| Baer      | 204 | 101 PR REP     |
| Higgins   | 205 | 101 AC_MGR     |
| Gietz     | 206 | 205 AC_ACCOUNT |
| De Haan   | 102 | 100 AD_VP      |
| Hunold    | 103 | 102 IT_PROG    |
| Ernst     | 104 | 103 IT_PROG    |
| Austin    | 105 | 103 IT_PROG    |
| Pataballa | 106 | 103 IT_PROG    |
| Lorentz   | 107 | 103 IT_PROG    |

Oracle Database does not return the manager Greenberg, although it does return employees who are managed by Greenberg.

The following statement is similar to the first one, except that it uses the LEVEL pseudocolumn to select only the first two levels of the management hierarchy:

```
SELECT LPAD(' ',2*(LEVEL-1)) || last_name org_chart,
employee_id, manager_id, job_id
  FROM employees
 WHERE job_id = 'AD_PRES'
CONNECT BY PRIOR employee_id = manager_id AND LEVEL <= 2;
```

| ORG_CHART | EMPLOYEE_ID | MANAGER_ID | JOB_ID  |
|-----------|-------------|------------|---------|
| King      | 100         |            | AD_PRES |
| Kochhar   | 101         | 100        | AD_VP   |
| De Haan   | 102         | 100        | AD_VP   |
| Raphaely  | 114         | 100        | PU_MAN  |
| Weiss     | 120         | 100        | ST_MAN  |
| Fripp     | 121         | 100        | ST_MAN  |
| Kaufling  | 122         | 100        | ST_MAN  |
| Vollman   | 123         | 100        | ST_MAN  |
| Mourgos   | 124         | 100        | ST_MAN  |
| Russell   | 145         | 100        | SA_MAN  |
| Partners  | 146         | 100        | SA_MAN  |
| Errazuriz | 147         | 100        | SA_MAN  |
| Cambrault | 148         | 100        | SA_MAN  |
| Zlotkey   | 149         | 100        | SA_MAN  |
| Hartstein | 201         | 100        | MK_MAN  |

### Using Distributed Queries: Example

This example shows a query that joins the departments table on the local database with the employees table on the remote database:

```
SELECT last_name, department_name
  FROM employees@remote, departments
 WHERE employees.department_id = departments.department_id;
```

### Using Correlated Subqueries: Examples

The following examples show the general syntax of a correlated subquery:

```
SELECT select_list
  FROM table1 t_alias1
```

```
WHERE expr operator
      (SELECT column_list
       FROM table2 t_alias2
       WHERE t_alias1.column
             operator t_alias2.column);

UPDATE table1 t_alias1
   SET column =
      (SELECT expr
       FROM table2 t_alias2
       WHERE t_alias1.column = t_alias2.column);

DELETE FROM table1 t_alias1
   WHERE column operator
      (SELECT expr
       FROM table2 t_alias2
       WHERE t_alias1.column = t_alias2.column);
```

The following statement returns data about employees whose salaries exceed their department average. The following statement assigns an alias to `employees`, the table containing the salary information, and then uses the alias in a correlated subquery:

```
SELECT department_id, last_name, salary
      FROM employees x
     WHERE salary > (SELECT AVG(salary)
                      FROM employees
                     WHERE x.department_id = department_id)
      ORDER BY department_id;
```

For each row of the `employees` table, the parent query uses the correlated subquery to compute the average salary for members of the same department. The correlated subquery performs the following steps for each row of the `employees` table:

1. The `department_id` of the row is determined.
2. The `department_id` is then used to evaluate the parent query.
3. If the salary in that row is greater than the average salary of the departments of that row, then the row is returned.

The subquery is evaluated once for each row of the `employees` table.

### Selecting from the DUAL Table: Example

The following statement returns the current date:

```
SELECT CURRENT_DATE FROM DUAL;
```

You could select `CURRENT_DATE` from the `employees` table, but the database would return 14 rows of the same `CURRENT_DATE`, one for every row of the `employees` table. Selecting from `DUAL` is more convenient.

From 23c you can omit the optional `FROM` clause as in the following example:

```
SELECT CURRENT_DATE;
```

### Selecting Sequence Values: Examples

The following statement increments the `employees_seq` sequence and returns the new value:

```
SELECT employees_seq.nextval
  FROM DUAL;
```

The following statement selects the current value of employees\_seq:

```
SELECT employees_seq.currval
  FROM DUAL;
```

### Row Pattern Matching: Example

This example uses row pattern matching to query stock price data. The following statements create table Ticker and inserts stock price data into the table:

```
CREATE TABLE Ticker (SYMBOL VARCHAR2(10), tstamp DATE, price NUMBER);

INSERT INTO Ticker VALUES('ACME', '01-Apr-11', 12);
INSERT INTO Ticker VALUES('ACME', '02-Apr-11', 17);
INSERT INTO Ticker VALUES('ACME', '03-Apr-11', 19);
INSERT INTO Ticker VALUES('ACME', '04-Apr-11', 21);
INSERT INTO Ticker VALUES('ACME', '05-Apr-11', 25);
INSERT INTO Ticker VALUES('ACME', '06-Apr-11', 12);
INSERT INTO Ticker VALUES('ACME', '07-Apr-11', 15);
INSERT INTO Ticker VALUES('ACME', '08-Apr-11', 20);
INSERT INTO Ticker VALUES('ACME', '09-Apr-11', 24);
INSERT INTO Ticker VALUES('ACME', '10-Apr-11', 25);
INSERT INTO Ticker VALUES('ACME', '11-Apr-11', 19);
INSERT INTO Ticker VALUES('ACME', '12-Apr-11', 15);
INSERT INTO Ticker VALUES('ACME', '13-Apr-11', 25);
INSERT INTO Ticker VALUES('ACME', '14-Apr-11', 25);
INSERT INTO Ticker VALUES('ACME', '15-Apr-11', 14);
INSERT INTO Ticker VALUES('ACME', '16-Apr-11', 12);
INSERT INTO Ticker VALUES('ACME', '17-Apr-11', 14);
INSERT INTO Ticker VALUES('ACME', '18-Apr-11', 24);
INSERT INTO Ticker VALUES('ACME', '19-Apr-11', 23);
INSERT INTO Ticker VALUES('ACME', '20-Apr-11', 22);
```

The following query uses row pattern matching to find all cases where stock prices dipped to a bottom price and then rose. This is generally called a V-shape. The resulting output contains only three rows because the query specifies ONE ROW PER MATCH, and three matches were found.

```
SELECT *
  FROM Ticker MATCH_RECOGNIZE (
    PARTITION BY symbol
    ORDER BY tstamp
    MEASURES STRT.tstamp AS start_tstamp,
             LAST(DOWN.tstamp) AS bottom_tstamp,
             LAST(UP.tstamp) AS end_tstamp
    ONE ROW PER MATCH
    AFTER MATCH SKIP TO LAST UP
    PATTERN (STRT DOWN+ UP+)
    DEFINE
      DOWN AS DOWN.price < PREV(DOWN.price),
      UP AS UP.price > PREV(UP.price)
    ) MR
  ORDER BY MR.symbol, MR.start_tstamp;

SYMBOL      START_TST BOTTOM_TS END_TSTAM
-----  -----  -----
ACME       05-APR-11 06-APR-11 10-APR-11
```

|      |           |           |           |
|------|-----------|-----------|-----------|
| ACME | 10-APR-11 | 12-APR-11 | 13-APR-11 |
| ACME | 14-APR-11 | 16-APR-11 | 18-APR-11 |

## SET CONSTRAINT[S]

### Purpose

Use the `SET CONSTRAINTS` statement to specify, for a particular transaction, whether a deferrable constraint is checked following each DML statement (`IMMEDIATE`) or when the transaction is committed (`DEFERRED`). You can use this statement to set the mode for a list of constraint names or for `ALL` constraints.

The `SET CONSTRAINTS` mode lasts for the duration of the transaction or until another `SET CONSTRAINTS` statement resets the mode.

#### Note:

You can also use an `ALTER SESSION` statement with the `SET CONSTRAINTS` clause to set *all* deferrable constraints. This is equivalent to making issuing a `SET CONSTRAINTS` statement at the start of each transaction in the current session.

You cannot specify this statement inside of a trigger definition.

`SET CONSTRAINTS` can be a distributed statement. Existing database links that have transactions in process are notified when a `SET CONSTRAINTS ALL` statement is issued, and new links are notified that it was issued as soon as they start a transaction.

### Prerequisites

To specify when a deferrable constraint is checked, you must have the `READ` or `SELECT` privilege on the table to which the constraint is applied unless the table is in your schema.

### Syntax

`set_constraints ::=`

### Semantics

#### `constraint`

Specify the name of one or more integrity constraints.

## ALL

Specify `ALL` to set all deferrable constraints for this transaction.

## IMMEDIATE

Specify `IMMEDIATE` to cause the specified constraints to be checked immediately on execution of each constrained DML statement. Oracle Database first checks any constraints that were deferred earlier in the transaction and then continues immediately checking constraints of any further statements in that transaction, as long as all the checked constraints are consistent and no other `SET CONSTRAINTS` statement is issued. If any constraint fails the check, then an error is signaled. At that point, a `COMMIT` statement causes the whole transaction to undo.

Making constraints immediate at the end of a transaction is a way of checking whether `COMMIT` can succeed. You can avoid unexpected rollbacks by setting constraints to `IMMEDIATE` as the last statement in a transaction. If any constraint fails the check, you can then correct the error before committing the transaction.

## DEFERRED

Specify `DEFERRED` to indicate that the conditions specified by the deferrable constraint are checked when the transaction is committed.

### Note:

You can verify the success of deferrable constraints prior to committing them by issuing a `SET CONSTRAINTS ALL IMMEDIATE` statement.

## Examples

### Setting Constraints: Examples

The following statement sets all deferrable constraints in this transaction to be checked immediately following each DML statement:

```
SET CONSTRAINTS ALL IMMEDIATE;
```

The following statement checks three deferred constraints when the transaction is committed. This example fails if the constraints were specified to be `NOT DEFERRABLE`.

```
SET CONSTRAINTS emp_job_nn, emp_salary_min,
hr.jhist_dept_fk@remote DEFERRED;
```

# SET ROLE

## Purpose

When a user logs on to Oracle Database, the database enables all privileges granted explicitly to the user and all privileges in the user's default roles. During the session, the user or an application can use the `SET ROLE` statement any number of times to enable or disable the roles currently enabled for the session.

You cannot enable more than 148 user-defined roles at one time.

**Note:**

- For most roles, you cannot enable or disable a role unless it was granted to you either directly or through other roles. However, a secure application role can be granted and enabled by its associated PL/SQL package. See the `CREATE ROLE` semantics for [USING package](#) and *Oracle Database Security Guide* for information about secure application roles.
- `SET ROLE` succeeds only if there are no definer's rights units on the call stack. If at least one DR unit is on the call stack, then issuing the `SET ROLE` command causes ORA-06565. See *Oracle Database PL/SQL Language Reference* for more information about definer's rights units.
- To run the `SET ROLE` command from PL/SQL, you must use dynamic SQL, preferably the `EXECUTE IMMEDIATE` statement. See *Oracle Database PL/SQL Language Reference* for more information about this statement.

You can see which roles are currently enabled by examining the `SESSION_ROLES` data dictionary view.

**See Also:**

- [CREATE ROLE](#) for information on creating roles
- [ALTER USER](#) for information on changing a user's default roles
- Oracle Database Reference* for information on the `SESSION_ROLES` session parameter

### Prerequisites

You must already have been granted the roles that you name in the `SET ROLE` statement.

### Syntax

`set_role ::=`

## Semantics

### *role*

Specify one or more roles to be enabled for the current session. All roles not specified are disabled for the current session or until another `SET ROLE` statement is issued in the current session.

In the `IDENTIFIED BY password` clause, specify the password for a role. If the role has a password, then you must specify the password to enable the role.

### Restriction on Setting Roles

You cannot specify a role identified globally. Global roles are enabled by default at login, and cannot be reenabled later.

### `IDENTIFIED BY`

You can set the password to a maximum length of 1024 bytes.

### `ALL` Clause

Specify `ALL` to enable all roles granted to you for the current session except those optionally listed in the `EXCEPT` clause.

Roles listed in the `EXCEPT` clause must be roles granted directly to you. They cannot be roles granted to you through other roles.

If you list a role in the `EXCEPT` clause that has been granted to you both directly and through another role, then the role remains enabled by virtue of the role to which it has been granted.

### Restrictions on the `ALL` Clause

The following restrictions apply to the `ALL` clause:

- You cannot use this clause to enable roles with passwords that have been granted directly to you.
- You cannot use this clause to enable a secure application role, which is a role that can be enabled only by applications using an authorized package. Refer to *Oracle Database Security Guide* for information on creating a secure application role and *Oracle Database 2 Day + Security Guide* for a tutorial.

### `NONE`

Specify `NONE` to disable all roles for the current session, including the `DEFAULT` role.

### Examples

#### Setting Roles: Examples

To enable the role `dw_manager` identified by a password for your current session, issue the following statement:

```
SET ROLE dw_manager IDENTIFIED BY password;
```

To enable all roles granted to you for the current session, issue the following statement:

```
SET ROLE ALL;
```

To enable all roles granted to you except dw\_manager, issue the following statement:

```
SET ROLE ALL EXCEPT dw_manager;
```

To disable all roles granted to you for the current session, issue the following statement:

```
SET ROLE NONE;
```

## SET TRANSACTION

### Purpose

Use the `SET TRANSACTION` statement to establish the current transaction as read-only or read/write, establish its isolation level, assign it to a specified rollback segment, or assign a name to the transaction.

A transaction implicitly begins with any operation that obtains a TX lock:

- When a statement that modifies data is issued
- When a `SELECT ... FOR UPDATE` statement is issued
- When a transaction is explicitly started with a `SET TRANSACTION` statement or the `DBMS_TRANSACTION` package

Issuing either a `COMMIT` or `ROLLBACK` statement explicitly ends the current transaction.

The operations performed by a `SET TRANSACTION` statement affect only your current transaction, not other users or other transactions. Your transaction ends whenever you issue a `COMMIT` or `ROLLBACK` statement. Oracle Database implicitly commits the current transaction before and after executing a data definition language (DDL) statement.

### See Also:

[COMMIT](#) and [ROLLBACK](#)

### Prerequisites

If you use a `SET TRANSACTION` statement, then it must be the first statement in your transaction. However, a transaction need not have a `SET TRANSACTION` statement.

### Syntax

`set_transaction ::=`

## Semantics

### READ ONLY

The `READ ONLY` clause establishes the current transaction as a read-only transaction. This clause establishes **transaction-level read consistency**.

All subsequent queries in that transaction see only changes that were committed before the transaction began. Read-only transactions are useful for reports that run multiple queries against one or more tables while other users update these same tables.

This clause is not supported for the user `SYS`. Queries by `SYS` will return changes made during the transaction even if `SYS` has set the transaction to be `READ ONLY`.

### Restriction on Read-only Transactions

Only the following statements are permitted in a read-only transaction:

- Subqueries—`SELECT` statements without the `for_update_clause`
- `LOCK TABLE`
- `SET ROLE`
- `ALTER SESSION`
- `ALTER SYSTEM`

### READ WRITE

Specify `READ WRITE` to establish the current transaction as a read/write transaction. This clause establishes **statement-level read consistency**, which is the default.

### Restriction on Read/Write Transactions

You cannot toggle between transaction-level and statement-level read consistency in the same transaction.

### ISOLATION LEVEL Clause

- The `SERIALIZABLE` setting specifies serializable transaction isolation mode as defined in the SQL standard. If a serializable transaction contains data manipulation language (DML) that attempts to update any resource that may have been updated in a transaction uncommitted at the start of the serializable transaction, then the DML statement fails.
- The `READ COMMITTED` setting is the default Oracle Database transaction behavior. If the transaction contains DML that requires row locks held by another transaction, then the DML statement waits until the row locks are released.

### USE ROLLBACK SEGMENT Clause

#### Note:

This clause is relevant and valid only if you are using rollback segments for undo. Oracle strongly recommends that you use automatic undo management to handle undo space. If you follow this recommendation and run your database in automatic undo mode, then Oracle Database ignores this clause.

Specify `USE ROLLBACK SEGMENT` to assign the current transaction to the specified rollback segment. This clause also implicitly establishes the transaction as a read/write transaction.

Parallel DML requires more than one rollback segment. Therefore, if your transaction contains parallel DML operations, then the database ignores this clause.

### NAME Clause

Use the `NAME` clause to assign a name to the current transaction. This clause is especially useful in distributed database environments when you must identify and resolve in-doubt transactions. The *string* value is limited to 255 bytes.

If you specify a name for a distributed transaction, then when the transaction commits, the name becomes the commit comment, overriding any comment specified explicitly in the `COMMIT` statement.

#### See Also:

*Oracle Database Concepts* for more information about transaction naming

## Examples

### Setting Transactions: Examples

The following statements could be run at midnight of the last day of every month to count the products and quantities on hand in the Toronto warehouse in the sample Order Entry (`oe`) schema. This report would not be affected by any other user who might be adding or removing inventory to a different warehouse.

```
COMMIT;  
  
SET TRANSACTION READ ONLY NAME 'Toronto';  
  
SELECT product_id, quantity_on_hand FROM inventories  
    WHERE warehouse_id = 5  
    ORDER BY product_id;  
  
COMMIT;
```

The first `COMMIT` statement ensures that `SET TRANSACTION` is the first statement in the transaction. The last `COMMIT` statement does not actually make permanent any changes to the database. It simply ends the read-only transaction.

# TRUNCATE CLUSTER

### Purpose

#### Note:

You cannot roll back a `TRUNCATE CLUSTER` statement.

Use the `TRUNCATE CLUSTER` statement to remove all rows from a cluster. By default, Oracle Database also performs the following tasks:

- Deallocates all space used by the removed rows except that specified by the `MINEXTENTS` storage parameter
- Sets the `NEXT` storage parameter to the size of the last extent removed from the segment by the truncation process

Removing rows with the `TRUNCATE` statement can be more efficient than dropping and re-creating a cluster. Dropping and re-creating a cluster invalidates dependent objects of the cluster, requires you to regrant object privileges on the cluster, and requires you to re-create the indexes and cluster on the table and respecify its storage parameters. Truncating has none of these effects.

Removing rows with the `TRUNCATE CLUSTER` statement can be faster than removing all rows with the `DELETE` statement, especially if the cluster has numerous indexes and other dependencies.

#### See Also:

- [DELETE](#) and [DROP CLUSTER](#) for information on other ways of dropping data from a cluster
- [TRUNCATE TABLE](#) for information on truncating a table

#### Prerequisites

To truncate a cluster, the cluster must be in your schema or you must have `DROP ANY TABLE` system privilege.

#### See Also:

["Restrictions on Truncating Tables"](#)

#### Syntax

`truncate_cluster::=`

#### Semantics

##### CLUSTER Clause

Specify the schema and name of the cluster to be truncated. You can truncate only an indexed cluster, not a hash cluster. If you omit `schema`, then the database assumes the cluster is in your own schema.

When you truncate a cluster, the database also automatically deletes all data in the indexes of the cluster tables.

### STORAGE Clauses

The `STORAGE` clauses let you determine what happens to the space freed by the truncated rows. The `DROP STORAGE` clause and `REUSE STORAGE` clause also apply to the space freed by the data deleted from associated indexes.

#### DROP STORAGE

Specify `DROP STORAGE` to deallocate all space from the deleted rows from the cluster except the space allocated by the `MINEXTENTS` parameter of the cluster. This space can subsequently be used by other objects in the tablespace. Oracle Database also sets the `NEXT` storage parameter to the size of the last extent removed from the segment in the truncation process. This is the default.

#### REUSE STORAGE

Specify `REUSE STORAGE` to retain the space from the deleted rows allocated to the cluster. Storage values are not reset to the values when the table or cluster was created. This space can subsequently be used only by new data in the cluster resulting from insert or update operations. This clause leaves storage parameters at their current settings.

If you have specified more than one free list for the object you are truncating, then the `REUSE STORAGE` clause also removes any mapping of free lists to instances and resets the high-water mark to the beginning of the first extent.

### Examples

#### Truncating a Cluster: Example

The following statement removes all rows from all tables in the `personnel` cluster, but leaves the freed space allocated to the tables:

```
TRUNCATE CLUSTER personnel REUSE STORAGE;
```

The preceding statement also removes all data from all indexes on the tables in the `personnel` cluster.

## TRUNCATE TABLE

### Purpose

#### Note:

You cannot roll back a `TRUNCATE TABLE` statement, nor can you use a `FLASHBACK TABLE` statement to retrieve the contents of a table that has been truncated.

Use the `TRUNCATE TABLE` statement to remove all rows from a table. By default, Oracle Database also performs the following tasks:

- Deallocates all space used by the removed rows except that specified by the MINEXTENTS storage parameter
- Sets the NEXT storage parameter to the size of the last extent removed from the segment by the truncation process

Removing rows with the TRUNCATE TABLE statement can be more efficient than dropping and re-creating a table. Dropping and re-creating a table invalidates dependent objects of the table, and requires you to repeat the following actions:

- Grant object privileges on the table
- Create the indexes, integrity constraints, and triggers on the table
- Specify the storage parameters of the table

Truncating has none of these effects.

Removing rows with the TRUNCATE TABLE statement can be faster than removing all rows with the DELETE statement, especially if the table has numerous triggers, indexes, and other dependencies.

#### See Also:

- [DELETE](#) and [DROP TABLE](#) for information on other ways of removing data from a table
- [TRUNCATE CLUSTER](#) for information on truncating a cluster

#### Prerequisites

To truncate a table, the table must be in your schema or you must have the `DROP ANY TABLE` system privilege.

To specify the `CASCADE` clause, all affected child tables must be in your schema or you must have the `DROP ANY TABLE` system privilege.

You can truncate a private temporary table with the existing `TRUNCATE TABLE` command. Truncating a private temporary table will not commit and existing transaction. This applies to both transaction-specific and session-specific private temporary tables. Note that a truncated private temporary table will not go into the `RECYCLEBIN`.

#### See Also:

- ["Restrictions on Truncating Tables"](#)

## Syntax

*truncate table*::=

## Semantics

## TABLE Clause

Specify the schema and name of the table to be truncated. This table cannot be part of a cluster. If you omit *schema*, then Oracle Database assumes the table is in your own schema.

- You can truncate index-organized tables and temporary tables. When you truncate a temporary table, only the rows created during the current session are removed.
  - Oracle Database changes the `NEXT` storage parameter of `table` to be the size of the last extent deleted from the segment in the process of truncation.
  - Oracle Database also automatically truncates and resets any existing `UNUSABLE` indicators for the following indexes on `table`: range and hash partitions of local indexes and subpartitions of local indexes.
  - If `table` is not empty, then the database marks `UNUSABLE` all nonpartitioned indexes and all partitions of global partitioned indexes on the table. However, when the table is truncated, the index is also truncated, and a new high water mark is calculated for the index segment. This operation is equivalent to creating a new segment for the index. Therefore, at the end of the truncate operation, the indexes are once again `USABLE`.
  - For a domain index, this statement invokes the appropriate truncate routine to truncate the domain index data.

## See Also:

*Oracle Database Data Cartridge Developer's Guide* for more information on domain indexes

- If a regular or index-organized table contains LOB columns, then all LOB data and LOB index segments are truncated.
  - If *table* is partitioned, then all partitions or subpartitions, as well as the LOB data and LOB index segments for each partition or subpartition, are truncated.

 **Note:**

When you truncate a table, Oracle Database automatically removes all data in the table's indexes and any materialized view direct-path `INSERT` information held in association with the table. This information is independent of any materialized view log. If this direct-path `INSERT` information is removed, then an incremental refresh of the materialized view may lose data.

- All cursors are invalidated.

### Restrictions on Truncating Tables

This statement is subject to the following restrictions:

- You cannot roll back a `TRUNCATE TABLE` statement.
- You cannot flash back to the state of the table before the truncate operation.
- You cannot individually truncate a table that is part of a cluster. You must either truncate the cluster, delete all rows from the table, or drop and re-create the table.
- You cannot truncate the parent table of an enabled foreign key constraint. You must disable the constraint before truncating the table. An exception is that you can truncate the table if the integrity constraint is self-referential.
- If a domain index is defined on `table`, then neither the index nor any index partitions can be marked `IN_PROGRESS`.
- You cannot truncate the parent table of a reference-partitioned table. You must first drop the reference-partitioned child table.
- You cannot truncate a duplicated table.

### MATERIALIZED VIEW LOG Clause

The `MATERIALIZED VIEW LOG` clause lets you specify whether a materialized view log defined on the table is to be preserved or purged when the table is truncated. This clause permits materialized view master tables to be reorganized through export or import without affecting the ability of primary key materialized views defined on the master to be fast refreshed. To support continued fast refresh of primary key materialized views, the materialized view log must record primary key information.

 **Note:**

The keyword `SNAPSHOT` is supported in place of `MATERIALIZED VIEW` for backward compatibility.

### PRESERVE

Specify `PRESERVE` if any materialized view log should be preserved when the master table is truncated. This is the default.

### PURGE

Specify `PURGE` if any materialized view log should be purged when the master table is truncated.

 **See Also:**

*Oracle Database Administrator's Guide* for more information about materialized view logs and the TRUNCATE statement

## STORAGE Clauses

The STORAGE clauses let you determine what happens to the space freed by the truncated rows. The DROP STORAGE clause, DROP ALL STORAGE clause, and REUSE STORAGE clause also apply to the space freed by the data deleted from associated indexes.

### DROP STORAGE

Specify DROP STORAGE to deallocate all space from the deleted rows from the table except the space allocated by the MINEXTENTS parameter of the table. This space can subsequently be used by other objects in the tablespace. Oracle Database also sets the NEXT storage parameter to the size of the last extent removed from the segment in the truncation process. This setting, which is the default, is useful for small and medium-sized objects. The extent management in locally managed tablespace is very fast in these cases, so there is no need to reserve space.

### DROP ALL STORAGE

Specify DROP ALL STORAGE to deallocate all space from the deleted rows from the table, including the space allocated by the MINEXTENTS parameter. All segments for the table, as well as all segments for its dependent objects, will be deallocated.

### Restrictions on DROP ALL STORAGE

This clause is subject to the same restrictions as described in "[Restrictions on Deferred Segment Creation](#)".

### REUSE STORAGE

Specify REUSE STORAGE to retain the space from the deleted rows allocated to the table. Storage values are not reset to the values when the table was created. This space can subsequently be used only by new data in the table resulting from insert or update operations. This clause leaves storage parameters at their current settings.

This setting is useful as an alternative to deleting all rows of a very large table—when the number of rows is very large, the table entails many thousands of extents, and when data is to be reinserted in the future.

This clause is not valid for temporary tables. A session becomes unbound from the temporary table when the table is truncated, so the storage is automatically dropped.

If you have specified more than one free list for the object you are truncating, then the REUSE STORAGE clause also removes any mapping of free lists to instances and resets the high-water mark to the beginning of the first extent.

### CASCADE

If you specify CASCADE, then Oracle Database truncates all child tables that reference *table* with an enabled ON DELETE CASCADE referential constraint. This is a recursive

operation that will truncate all child tables, grandchild tables, and so on, using the specified options.

## Examples

### Truncating a Table: Example

The following statement removes all rows from a hypothetical copy of the sample table `hr.employees` and returns the freed space to the tablespace containing `employees`:

```
TRUNCATE TABLE employees_demo;
```

The preceding statement also removes all data from all indexes on `employees` and returns the freed space to the tablespaces containing them.

### Preserving Materialized View Logs After Truncate: Example

The following statements are examples of `TRUNCATE` statements that preserve materialized view logs:

```
TRUNCATE TABLE sales_demo PRESERVE MATERIALIZED VIEW LOG;
```

```
TRUNCATE TABLE orders_demo;
```

# UPDATE

## Purpose

Use the `UPDATE` statement to change existing values in a table or in the base table of a view or the master table of a materialized view.

## Prerequisites

For you to update values in a table, the table must be in your own schema or you must have the `UPDATE` object privilege on the table.

For you to update values in the base table of a view:

- You must have the `UPDATE` object privilege on the view, and
- Whoever owns the schema containing the view must have the `UPDATE` object privilege on the base table.

The `UPDATE ANY TABLE` system privilege also allows you to update values in any table or in the base table of any view.

To update values in an object on a remote database, you must also have the `READ` or `SELECT` object privilege on the object.

If the `SQL92_SECURITY` initialization parameter is set to `TRUE` and the `UPDATE` operation references table columns, such as the columns in a `where_clause`, then you must also have the `SELECT` object privilege on the object you want to update.

## Syntax

**update ::=**

(*DML\_table\_expression\_clause ::=, update\_set\_clause ::=, where\_clause ::=, returning\_clause ::=, error\_logging\_clause ::=, from\_using\_clause ::=*)

**DML\_table\_expression\_clause ::=**

(*partition\_extension\_clause ::=, subquery ::=--part of SELECT, subquery\_restriction\_clause ::=, table\_collection\_expression ::=*)

**partition\_extension\_clause ::=**

**subquery\_restriction\_clause ::=**

### ***table\_collection\_expression ::=***

### *update\_set\_clause*::=

*from using clause::=*

**where clause ::=**

*order\_by\_clause*::=

See [order by clause](#)::=

*returning clause*::=

***error\_logging\_clause::=*****Semantics*****hint***

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

You can place a parallel hint immediately after the `UPDATE` keyword to parallelize both the underlying scan and `UPDATE` operations.

**See Also:**

- "["Hints"](#) for the syntax and description of hints
- [Oracle Database Concepts](#) for detailed information about parallel execution

***DML\_table\_expression\_clause***

The `ONLY` clause applies only to views. Specify `ONLY` syntax if the view in the `UPDATE` clause is a view that belongs to a hierarchy and you do not want to update rows from any of its subviews.

**See Also:**

- ["Restrictions on the DML\\_table\\_expression\\_clause"](#) and ["Updating a Table: Examples"](#)

***schema***

Specify the schema containing the object to be updated. If you omit `schema`, then the database assumes the object is in your own schema.

***table | view | materialized\_view | subquery***

Specify the name of the table, view, materialized view, or the columns returned by a subquery to be updated. Issuing an UPDATE statement against a table fires any UPDATE triggers associated with the table.

- If you specify *view*, then the database updates the base table of the view. You cannot update a view except with INSTEAD OF triggers if the defining query of the view contains one of the following constructs:

- A set operator
- A DISTINCT operator
- An aggregate or analytic function
- A GROUP BY, ORDER BY, MODEL, CONNECT BY, or START WITH clause
- A collection expression in a SELECT list
- A subquery in a SELECT list
- A subquery designated WITH READ ONLY
- A recursive WITH clause
- Joins, with some exceptions, as documented in *Oracle Database Administrator's Guide*

- You cannot update more than one base table through a view.
- In addition, if the view was created with the WITH CHECK OPTION, then you can update the view only if the resulting data satisfies the view's defining query.
- If *table* or the base table of *view* contains one or more domain index columns, then this statement executes the appropriate indextype update routine.
- You cannot update rows in a read-only materialized view. If you update rows in a writable materialized view, then the database updates the rows from the underlying container table. However, the updates are overwritten at the next refresh operation. If you update rows in an updatable materialized view that is part of a materialized view group, then the database also updates the corresponding rows in the master table.

#### See Also:

- *Oracle Database Data Cartridge Developer's Guide* for more information on the indextype update routines
- [CREATE MATERIALIZED VIEW](#) for information on creating updatable materialized views

#### ***partition\_extension\_clause***

Specify the name or partition key value of the partition or subpartition within *table* targeted for updates. You need not specify the partition name when updating values in a partitioned table. However in some cases specifying the partition name can be more efficient than a complicated *where\_clause*.

 **See Also:**

"[References to Partitioned Tables and Indexes](#)" and "[Updating a Partition: Example](#)"

***dblink***

Specify a complete or partial name of a database link to a remote database where the object is located. You can use a database link to update a remote object only if you are using Oracle Database distributed functionality.

If you omit *dblink*, then the database assumes the object is on the local database.

 **Note:**

Starting with Oracle Database 12c Release 2 (12.2), the `UPDATE` statement accepts remote LOB locators as bind variables. Refer to the "Distributed LOBs" chapter in *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information.

 **See Also:**

"[References to Objects in Remote Databases](#)" for information on referring to database links

***subquery\_restriction\_clause***

Use the `subquery_restriction_clause` to restrict the subquery in one of the following ways:

**WITH READ ONLY**

Specify `WITH READ ONLY` to indicate that the table or view cannot be updated.

**WITH CHECK OPTION**

Specify `WITH CHECK OPTION` to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the `FROM` clause but not in subquery in the `WHERE` clause.

**CONSTRAINT *constraint***

Specify the name of the `CHECK OPTION` constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form `SYS_Cn`, where *n* is an integer that makes the constraint name unique within the database.

 **See Also:**

"[Using the WITH CHECK OPTION Clause: Example](#)"

### ***table\_collection\_expression***

The *table\_collection\_expression* lets you inform Oracle that the value of *collection\_expression* should be treated as a table for purposes of query and DML operations. The *collection\_expression* can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called **collection unnesting**.

The optional plus (+) is relevant if you are joining the **TABLE** collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

 **Note:**

In earlier releases of Oracle, when *collection\_expression* was a subquery, *table\_collection\_expression* was expressed as THE *subquery*. That usage is now deprecated.

You can use a *table\_collection\_expression* to update rows in one table based on rows from another table. For example, you could roll up four quarterly sales tables into a yearly sales table.

### ***t\_alias***

Specify a **correlation name** (alias) for the table, view, or subquery to be referenced elsewhere in the statement. This alias is required if the *DML\_table\_expression\_clause* references any object type attributes or object type methods.

 **See Also:**

"[Correlated Update: Example](#)"

### **Restrictions on the *DML\_table\_expression\_clause***

This clause is subject to the following restrictions:

- You cannot execute this statement if *table* or the base table of *view* contains any domain indexes marked **IN\_PROGRESS** or **FAILED**.
- You cannot insert into a partition if any affected index partitions are marked **UNUSABLE**.
- You cannot specify the *order\_by\_clause* in the subquery of the *DML\_table\_expression\_clause*.

- If you specify an index, index partition, or index subpartition that has been marked UNUSABLE, then the UPDATE statement will fail unless the SKIP\_UNUSABLE\_INDEXES session parameter has been set to TRUE.

 **See Also:**

[ALTER SESSION](#) for information on the SKIP\_UNUSABLE\_INDEXES session parameter

### ***update\_set\_clause***

The *update\_set\_clause* lets you set column values.

#### ***column***

Specify the name of a column of the object that is to be updated. If you omit a column of the table from the *update\_set\_clause*, then the value of that column remains unchanged.

If *column* refers to a LOB object attribute, then you must first initialize it with a value of empty or null. You cannot update it with a literal. Also, if you are updating a LOB value using some method other than a direct UPDATE SQL statement, then you must first lock the row containing the LOB. See [for\\_update\\_clause](#) for more information.

If *column* is a virtual column, you cannot specify it here. Rather, you must update the values from which the virtual column is derived.

If *column* is part of the partitioning key of a partitioned table, then UPDATE will fail if you change a value in the column that would move the row to a different partition or subpartition, unless you enable row movement. Refer to the *row\_movement\_clause* of [CREATE TABLE](#) or [ALTER TABLE](#).

In addition, if *column* is part of the partitioning key of a list-partitioned table, then UPDATE will fail if you specify a value for the column that does not already exist in the *partition\_key\_value* list of one of the partitions.

#### ***subquery***

Specify a subquery that returns exactly one row for each row updated.

- If you specify only one column in the *update\_set\_clause*, then the subquery can return only one value.
- If you specify multiple columns in the *update\_set\_clause*, then the subquery must return as many values as you have specified columns.
- If the subquery returns no rows, then the column is assigned a null.
- If this *subquery* refers to remote objects, then the UPDATE operation can run in parallel as long as the reference does not loop back to an object on the local database. However, if the *subquery* in the *DML\_table\_expression\_clause* refers to any remote objects, then the UPDATE operation will run serially without notification.

You can use the *flashback\_query\_clause* within the subquery to update *table* with past data. Refer to the [flashback\\_query\\_clause](#) of [SELECT](#) for more information on this clause.

 **See Also:**

- [SELECT and "Using Subqueries "](#)
- [parallel\\_clause in the CREATE TABLE documentation](#)

**expr**

Specify an expression that resolves to the new value assigned to the corresponding column.

 **Note:**

[Expressions for the syntax of expr and "Updating an Object Table: Example"](#)

**DEFAULT**

Specify **DEFAULT** to set the column to the value previously specified as the default value for the column. If no default value for the corresponding column has been specified, then the database sets the column to null.

**Restriction on Updating to Default Values**

You cannot specify **DEFAULT** if you are updating a view.

You cannot use the **DEFAULT** clause in an **UPDATE** statement if the table that you are specifying has an Oracle Label Security policy enabled.

**VALUE Clause**

The **VALUE** clause lets you specify the entire row of an object table.

**Restriction on the VALUE clause**

You can specify this clause only for an object table.

 **Note:**

If you insert string literals into a **RAW** column, then during subsequent queries, Oracle Database will perform a full table scan rather than using any index that might exist on the **RAW** column.

 **See Also:**

["Updating an Object Table: Example"](#)

### ***from\_using\_clause***

Use this clause to filter the rows UPDATE changes, or to provide the values for the columns in the target table. Specify the join conditions in the *where\_clause*. You can outer join source tables to the target table with (+). The target table cannot be the outer table in the join.

You can join many tables, views, and inline views. Specify the join conditions in the *where\_clause* or use the *join\_clause* to join these to each other with ANSI join syntax.

You can specify the same table in the *dml\_table\_expression\_clause* and *from\_clause*. When you do so they must have unique aliases.

#### **Example: Update With Direct-Join**

In this example, the join condition between table employees e and table jobs j determines which rows of employees are updated. The column `jobs.max_salary` supplies the new values for `employees.salary`:

```
UPDATE employees e
SET   e.salary = j.max_salary
FROM  jobs j
WHERE j.job_id = e.job_id;
```

Direct joins for UPDATE have the same semantics and restrictions as SELECT in the *from\_clause* and *where\_clause*. The target table has the same restrictions as UPDATE. Triggers on the target table fire as normal.

#### **Restrictions**

- You cannot specify ANSI join syntax involving the *dml\_table\_expression\_clause*. However, ANSI join syntax is allowed between the tables specified in the FROM clause. Right and full outer joins are not allowed.
- The UPDATE can change each row at most once. If the join condition results in the same row being updated more than once, the statement will raise an ORA-30926 error.
- You can only specify one table, view, or materialized view in *dml\_table\_expression\_clause* when the *from\_clause* is present.
- The left-hand side of *update\_set\_clause* must be a column from the *dml\_table\_expression\_clause* and not from the *from\_clause*.
- You can use a lateral view in the FROM clause, but it cannot reference a column from the update target. It may be outer-joined.
- Order by position is not allowed in the *order\_by\_clause*.
- UPDATE with *from\_clause* supports *returning\_clause* and *error\_logging\_clause*.
- Hint clause can be used to specify instructions to the optimizer for joins involving the *from\_clause*.

### ***where\_clause***

The *where\_clause* lets you restrict the rows updated to those for which the specified *condition* is true. If you omit this clause, then the database updates all rows in the table or view. Refer to [Conditions](#) for the syntax of *condition*.

The *where\_clause* determines the rows in which values are updated. If you do not specify the *where\_clause*, then all rows are updated. For each row that satisfies the *where\_clause*, the columns to the left of the equality operator (=) in the *update\_set\_clause* are set to the values of the corresponding expressions to the right of the operator. The expressions are evaluated as the row is updated.

#### ***order\_by\_clause***

The following restrictions apply to the ORDER BY clause:

- When used in an analytic function, the *order\_by\_clause* must take an expression *expr*.
- The SIBLINGS keyword is not valid (it is relevant only in hierarchical queries)
- The *position* alias is invalid.

See [order\\_by\\_clause](#)

#### ***returning\_clause***

You can specify this clause for tables, views, and materialized views with a single base table.

When operating on a single row, a DML statement with a *returning\_clause* can retrieve column values using the affected row, rowid, and REFS to the affected row and store them in host variables or PL/SQL variables.

When operating on multiple rows, a DML statement with the *returning\_clause* returns values from expressions, rowids, and REFS involving the affected rows in bind arrays.

#### ***expr***

Each item in the *expr* list must be a valid expression syntax.

#### **INTO**

The INTO clause indicates that the values of the changed rows are to be stored in the variable(s) specified in *data\_item* list.

#### ***data\_item***

Each *data\_item* is a host variable or PL/SQL variable that stores the retrieved *expr* value.

For each expression in the RETURNING list, you must specify a corresponding type-compatible PL/SQL variable or host variable in the INTO list.

Given columns *c1* and *c2* in a table, you can specify OLD for a column *c1*, (for example OLD *c1*). You can also specify OLD for a column referenced by a column expression (for example *c1+OLD c2*). When OLD is specified for a column, the column value before the update is returned. In the case of a column referenced by a column expression, what is returned is the result from evaluating the column expression using the column value before the update.

NEW can be explicitly specified for a column, or column referenced in an expression to return a column value after the update, or an expression result that uses the after update value of a column.

When OLD and NEW are both omitted for a column or an expression, the after update column value, or expression result computed using after update column values, is returned.

#### **Restrictions**

The following restrictions apply to the RETURNING clause:

- The `expr` is restricted as follows:
  - For `UPDATE` and `DELETE` statements each `expr` must be a simple expression or a single-set aggregate function expression. You cannot combine simple expressions and single-set aggregate function expressions in the same `returning_clause`. For `INSERT` statements, each `expr` must be a simple expression. Aggregate functions are not supported in an `INSERT` statement `RETURNING` clause.
  - Single-set aggregate function expressions cannot include the `DISTINCT` keyword.
- If the `expr` list contains a primary key column or other `NOT NULL` column, then the update statement fails if the table has a `BEFORE UPDATE` trigger defined on it.
- You cannot specify the `returning_clause` for a multitable insert.
- You cannot use this clause with parallel DML or with remote objects.
- You cannot retrieve `LONG` types with this clause.
- You cannot specify this clause for a view on which an `INSTEAD OF` trigger has been defined.

#### See Also:

*Oracle Database PL/SQL Language Reference* for information on using the `BULK COLLECT` clause to return multiple values to collection variables

#### `error_logging_clause`

The `error_logging_clause` has the same behavior in an `UPDATE` statement as it does in an `INSERT` statement. Refer to the `INSERT` statement `error_logging_clause` for more information.

"[Inserting Into a Table with Error Logging: Example](#)"

## Examples

### Updating a Table: Examples

The following statement gives null commissions to all employees with the job `SH_CLERK`:

```
UPDATE employees
   SET commission_pct = NULL
 WHERE job_id = 'SH_CLERK';
```

The following statement promotes Douglas Grant to manager of Department 20 with a \$1,000 raise:

```
UPDATE employees SET
    job_id = 'SA_MAN', salary = salary + 1000, department_id = 120
    WHERE first_name||' '|last_name = 'Douglas Grant';
```

The following statement increases the salary of an employee in the `employees` table on the remote database:

```
UPDATE employees@remote
    SET salary = salary*1.1
    WHERE last_name = 'Baer';
```

The next example shows the following syntactic constructs of the `UPDATE` statement:

- Both forms of the `update_set_clause` together in a single statement
- A correlated subquery
- A `where_clause` to limit the updated rows

```
UPDATE employees a
    SET department_id =
        (SELECT department_id
            FROM departments
            WHERE location_id = '2100'),
    (salary, commission_pct) =
        (SELECT 1.1*AVG(salary), 1.5*AVG(commission_pct)
            FROM employees b
            WHERE a.department_id = b.department_id)
    WHERE department_id IN
        (SELECT department_id
            FROM departments
            WHERE location_id = 2900
            OR location_id = 2700);
```

The preceding `UPDATE` statement performs the following operations:

- Updates only those employees who work in Geneva or Munich (locations 2900 and 2700)
- Sets `department_id` for these employees to the `department_id` corresponding to Bombay (`location_id` 2100)
- Sets each employee's salary to 1.1 times the average salary of their department
- Sets each employee's commission to 1.5 times the average commission of their department

### Updating a Partition: Example

The following example updates values in a single partition of the `sales` table:

```
UPDATE sales PARTITION (sales_q1_1999) s
    SET s.promo_id = 494
    WHERE amount_sold > 1000;
```

### Updating an Object Table: Example

The following statement creates two object tables, `people_demo1` and `people_demo2`, of the `people_typ` object created in [Table Collections: Examples](#). The example shows how to update a row of `people_demo1` by selecting a row from `people_demo2`:

```
CREATE TABLE people_demo1 OF people_typ;
CREATE TABLE people_demo2 OF people_typ;
```

```
UPDATE people_demo1 p SET VALUE(p) =
  (SELECT VALUE(q) FROM people_demo2 q
   WHERE p.department_id = q.department_id)
 WHERE p.department_id = 10;
```

The example uses the `VALUE` object reference function in both the `SET` clause and the subquery.

### Correlated Update: Example

For an example that uses a correlated subquery to update nested table rows, refer to "[Table Collections: Examples](#)".

### Using the RETURNING Clause During UPDATE: Example

The following example returns values from the updated row and stores the result in PL/SQL variables `bnd1`, `bnd2`, `bnd3`:

```
UPDATE employees
  SET job_id ='SA_MAN', salary = salary + 1000, department_id = 140
  WHERE last_name = 'Jones'
  RETURNING salary*0.25, last_name, department_id
    INTO :bnd1, :bnd2, :bnd3;
```

The following example shows that you can specify a single-set aggregate function in the expression of the returning clause:

```
UPDATE employees
  SET salary = salary * 1.1
  WHERE department_id = 100
  RETURNING SUM(salary) INTO :bnd1;
```

### Update Using Direct Join: Example

The following example sets every employee's salary to the max salary for their job:

```
UPDATE hr.employees e
  SET e.salary = j.max_salary
  FROM hr.jobs j
  WHERE e.job_id = j.job_id;
```

# A

## How to Read Syntax Diagrams

This appendix describes how to read syntax diagrams.

This reference presents Oracle SQL syntax in both graphic diagrams and in text (Backus-Naur Form—BNF). This appendix contains these sections:

- [Graphic Syntax Diagrams](#)
- [Backus-Naur Form Syntax](#)

### Graphic Syntax Diagrams

Syntax diagrams are drawings that illustrate valid SQL syntax. To read a diagram, trace it from left to right, in the direction shown by the arrows.

Commands and other keywords appear in UPPERCASE inside rectangles. Type them exactly as shown in the rectangles. Parameters appear in lowercase inside ovals. Variables are used for the parameters. Punctuation, operators, delimiters, and terminators appear inside circles.

If the syntax diagram has more than one path, then you can choose any path. For example, in the following syntax you can specify either NOPARALLEL or PARALLEL:

***parallel\_clause ::=***

If you have the choice of more than one keyword, operator, or parameter, then your options appear in a vertical list. For example, in the following syntax diagram, you can specify one or more of the four parameters in the stack:

***physical\_attributes\_clause ::=***

The following table shows parameters that appear in the syntax diagrams and provides examples of the values you might substitute for them in your statements:

**Table A-1 Syntax Parameters**

| Parameter                             | Description                                                                                                                                                                       | Examples                                     |
|---------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|
| <i>table</i>                          | The substitution value must be the name of an object of the type specified by the parameter. For a list of all types of objects, see the section, "Schema Objects".               | employees                                    |
| <i>c</i>                              | The substitution value must be a single character from your database character set.                                                                                               | T<br>s                                       |
| 'text'                                | The substitution value must be a text string in single quotation marks. See the syntax description of 'text' in "Text Literals".                                                  | 'Employee records'                           |
| <i>char</i>                           | The substitution value must be an expression of data type CHAR or VARCHAR2 or a character literal in single quotation marks.                                                      | last_name<br>'Smith'                         |
| <i>condition</i>                      | The substitution value must be a condition that evaluates to TRUE or FALSE. See the syntax description of <i>condition</i> in Conditions.                                         | last_name > 'A'                              |
| <i>date</i><br><i>d</i>               | The substitution value must be a date constant or an expression of DATE data type.                                                                                                | TO_DATE(<br>'01-Jan-2002',<br>'DD-MON-YYYY') |
| <i>expr</i>                           | The substitution value can be an expression of any data type as defined in the syntax description of <i>expr</i> in "About SQL Expressions".                                      | salary + 1000                                |
| <i>integer</i>                        | The substitution value must be an integer as defined by the syntax description of <i>integer</i> in "Integer Literals".                                                           | 72                                           |
| <i>number</i><br><i>m</i><br><i>n</i> | The substitution value must be an expression of NUMBER data type or a number constant as defined in the syntax description of <i>number</i> in "Numeric Literals".                | AVG(salary)<br>15 * 7                        |
| <i>raw</i>                            | The substitution value must be an expression of data type RAW.                                                                                                                    | HEXTORAW('7D')                               |
| <i>subquery</i>                       | The substitution value must be a SELECT statement that will be used in another SQL statement. See <i>SELECT</i> .                                                                 | SELECT last_name<br>FROM employees           |
| <i>db_name</i>                        | The substitution value must be the name of a nondefault database in an embedded SQL program.                                                                                      | sales_db                                     |
| <i>db_string</i>                      | The substitution value must be the database identification string for an Oracle Net database connection. For details, see the user's guide for your specific Oracle Net protocol. | —                                            |

## Required Keywords and Parameters

Required keywords and parameters can appear singly or in a vertical list of alternatives. Single required keywords and parameters appear on the main path,

which is the horizontal line you are currently traveling. In the following example, `library_name` is a required parameter:

***drop\_library ::=***

If there is a library named `HQ_LIB`, then, according to the diagram, the following statement is valid:

```
DROP LIBRARY hq_lib;
```

If multiple keywords or parameters appear in a vertical list that intersects the main path, then one of them is required. You must choose one of the keywords or parameters, but not necessarily the one that appears on the main path. In the following example, you must choose `ALL`, `STANDBY`, or `NONE`:

***security\_clause ::=***

## Optional Keywords and Parameters

If keywords and parameters appear in a vertical list above the main path, then they are optional. In the following example, instead of traveling down a vertical line, you can continue along the main path:

***deallocate\_unused\_clause ::=***

***size\_clause ::=***

According to the diagrams, all of the following statements are valid:

```
DEALLOCATE UNUSED;
DEALLOCATE UNUSED KEEP 1000;
DEALLOCATE UNUSED KEEP 10G;
DEALLOCATE UNUSED 8T;
```

## Syntax Loops

Loops let you repeat the syntax within them as many times as you like. In the following example, after choosing one value expression, you can go back repeatedly to choose another, separated by commas.

***query\_partition\_clause ::=***

## Multipart Diagrams

Read a multipart diagram as if all the main paths were joined end to end. The following example is a three-part diagram:

***alter\_java ::=***

According to the diagram, the following statement is valid:

```
ALTER JAVA SOURCE jsource_1 COMPILE;
```

## Backus-Naur Form Syntax

Each graphic syntax diagram in this reference is followed by a link to a text description of the graphic. The text descriptions consist of a simple variant of Backus-Naur Form (BNF) that includes the following symbols and conventions:

| Symbol or Convention | Meaning                                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [ ]                  | Brackets enclose optional items.                                                                                                                                                                                                             |
| { }                  | Braces enclose items only one of which is required.                                                                                                                                                                                          |
|                      | A vertical bar separates alternatives within brackets or braces.                                                                                                                                                                             |
| ...                  | Ellipsis points show that the preceding syntactic element can be repeated.                                                                                                                                                                   |
| delimiters           | Delimiters other than brackets, braces, vertical bars, and ellipses must be entered as shown.                                                                                                                                                |
| <b>boldface</b>      | Words appearing in boldface are keywords. They must be typed as shown. (Keywords are case-sensitive in some, but not all, operating systems.) Words that are not in boldface are placeholders for which you must substitute a name or value. |

# B

## Automatic and Manual Locking Mechanisms During SQL Operations

This appendix describes mechanisms that lock data either automatically or as specified by the user during SQL statements. For a general discussion of locking mechanisms in the context of data concurrency and consistency, see *Oracle Database Concepts*.

This appendix contains the following sections:

- [Automatic Locks in DML Operations](#)
- [Automatic Locks in DDL Operations](#)
- [Manual Data Locking](#)
- [List of Nonblocking DDLs](#)

### List of Nonblocking DDLs

#### Release 23

The following nonblocking DDLs are added in Release 23.3:

- alter table add column
- alter table set column unused
- alter table add constraint enable novalidate
- alter table drop constraint

#### Release 21

The following nonblocking DDLs are added in Release 21c:

- alter table modify default attributes tablespace
- alter table modify default attributes lob tablespace
- alter index modify default attributes tablespace
- alter table modify default attributes for partition tablespace
- alter table modify default attributes for partition lob tablespace
- alter index modify default attributes for partition tablespace

#### Release 12.2.0.2

##### List of Nonblocking DDLs Added in 12.2.0.2

- Alter table merge partition online
- alter table modify partition by .. online (to change the partitioning schema of a table)

## Release 12.2.0.1

### List of Nonblocking DDLs Added in 12.2.0.1

- alter table split partition [subpartition] online
- alter table move online (move of a non-partitioned table)
- alter table modify partition by .. online (to convert a non-partitioned table to partitioned state)

## Release 12.1

The following nonblocking DDLs are added as of Release 12.1. Some nonblocking DDLs are downgraded to blocking in the presence of supplemental logging.

### List of Nonblocking DDLs Added in 12.1

- drop index online
- alter index unusable online
- alter table move partition online
- alter table move subpartition online

### List of Nonblocking DDLs Added in 12.1 that Downgrade to Blocking During Supplemental Logging

- alter table set unused column online
- alter table drop constraint online
- alter table modify column visible / invisible
- alter table add nullable column with default value

## Release 11.2

The following nonblocking DDLs are added as of Release 11.2. Some nonblocking DDLs are downgraded to blocking in the presence of supplemental logging.

### List of Nonblocking DDLs Added in 11.2

- create index online
- alter index rebuild online
- alter index rebuild partition online
- alter index rebuild subpartition online
- alter index visible / novisible

### List of Nonblocking DDLs Added in 11.2 that Downgrade to Blocking During Supplemental Logging

- alter table add column not null with default value
- alter table add constraint enable novalidate
- alter table modify constraint validate
- alter table add column (without any default)

# Automatic Locks in DML Operations

The purpose of a DML lock, also called a **data lock**, is to guarantee the integrity of data being accessed concurrently by multiple users. For example, a DML lock can prevent multiple customers from buying the last copy of a book available from an online bookseller. DML locks prevent destructive interference of simultaneous conflicting DML or DDL operations.

DML statements automatically acquire locks at both the table level and the row level. In the sections that follow, the acronym in parentheses after each type of lock or lock mode is the abbreviation used in the Locks Monitor of Oracle Enterprise Manager. Enterprise Manager might display "TM" for any table lock, rather than indicate the mode of table lock (such as RS or SRX).

The types of row and table locks are summarized here. For a more complete discussion of the types of row and table locks, see *Oracle Database Concepts*.

## Row Locks (TX)

A **row lock**, also called a **TX lock**, is a lock on a single row of a table. A transaction acquires a row lock for each row modified by one of the following statements: `INSERT`, `UPDATE`, `DELETE`, `MERGE`, and `SELECT ... FOR UPDATE`. The row lock exists until the transaction commits or rolls back.

When a transaction obtains a row lock for a row, the transaction also acquires a table lock for the table in which the row resides. The table lock prevents conflicting DDL operations that would override data changes in a current transaction.

## Table Locks (TM)

A transaction automatically acquires a table lock (**TM lock**) when a table is modified with the following statements: `INSERT`, `UPDATE`, `DELETE`, `MERGE`, and `SELECT ... FOR UPDATE`. These DML operations require table locks to reserve DML access to the table on behalf of a transaction and to prevent DDL operations that would conflict with the transaction. You can explicitly obtain a table lock using the `LOCK TABLE` statement, as described in "[Manual Data Locking](#)".

A table lock can be held in any of the following modes:

- A **row share lock (RS)**, also called a **subshare table lock (SS)**, indicates that the transaction holding the lock on the table has locked rows in the table and intends to update them. An SS lock is the least restrictive mode of table lock, offering the highest degree of concurrency for a table.
- A **row exclusive lock (RX)**, also called a **subexclusive table lock (SX)**, indicates that the transaction holding the lock has updated table rows or issued `SELECT ... FOR UPDATE`. An SX lock allows other transactions to query, insert, update, delete, or lock rows concurrently in the same table. Therefore, SX locks allow multiple transactions to obtain simultaneous SX and SS locks for the same table.
- A **share table lock (S)** held by one transaction allows other transactions to query the table (without using `SELECT ... FOR UPDATE`) but allows updates only if a single transaction holds the share table lock. Multiple transactions may hold a share table lock concurrently, so holding this lock is not sufficient to ensure that a transaction can modify the table.
- A **share row exclusive table lock (SRX)**, also called a **share-subexclusive table lock (SSX)**, is more restrictive than a share table lock. Only one transaction at a time can acquire an SSX lock on a given table. An SSX lock held by a transaction allows other

transactions to query the table (except for `SELECT ... FOR UPDATE`) but not to update the table.

- An **exclusive table lock (X)** is the most restrictive mode of table lock, allowing the transaction that holds the lock exclusive write access to the table. Only one transaction can obtain an X lock for a table.

 **See Also:**

["Manual Data Locking"](#)

### Locks in DML Operations

Oracle Database automatically obtains row-level and table-level locks on behalf of DML operations. The type of operation determines the locking behavior. [Table B-1](#) summarizes the information in this section.

 **Note:**

The implicit SX locks shown for the DML statements in [Table B-1](#) can sometimes be exclusive (X) locks for a short time owing to side effects from constraints.

**Table B-1 Summary of Locks Obtained by DML Statements**

| SQL Statement                                        | Row Locks | Table Lock Mode | RS             | RX             | S | SRX | X |
|------------------------------------------------------|-----------|-----------------|----------------|----------------|---|-----|---|
| <code>SELECT ... FROM table...</code>                | —         | none            | Y              | Y              | Y | Y   | Y |

<sup>1</sup> Yes, if no conflicting row locks are held by another transaction. Otherwise, waits occur.

## Locks When Rows Are Queried

A query can be explicit, as in the `SELECT` statement, or implicit, as in most `INSERT`, `MERGE`, `UPDATE`, and `DELETE` statements. The only DML statement that does not necessarily include a query component is an `INSERT` statement with a `VALUES` clause. Because queries only read data, they are the SQL statements least likely to interfere with other SQL statements.

The following characteristics apply to a query *without* the `FOR UPDATE` clause:

- The query acquires no data locks. Therefore, other transactions can query and update a table being queried, including the specific rows being queried. Because queries without the `FOR UPDATE` clause do not acquire any data locks to block other operations, such queries are often referred to as **nonblocking queries**.
- The query does not have to wait for any data locks to be released. Therefore, the query can always proceed. An exception to this rule is that queries may have to wait for data locks in some very specific cases of pending distributed transactions.

## Locks When Rows Are Modified

Some databases use a lock manager to maintain a list of locks in memory. Oracle Database, in contrast, stores lock information in the data block that contains the locked row. Each row lock affects only a single row.

Oracle Database uses a queuing mechanism for acquisition of row locks. If a transaction requires a row lock, and if the row is not already locked, then the transaction acquires a lock in the row's data block. The transaction itself has an entry in the **interested transaction list (ITL)** section of the block header. Each row modified by this transaction points to a copy of the transaction ID stored in the ITL. Thus, 100 rows in the same block modified by a single transaction require 100 row locks, but all 100 rows reference a single transaction ID.

When a transaction ends, the transaction ID remains in the ITL section of the data block header. If a new transaction wants to modify a row, then it uses the transaction ID to determine whether the lock is active. If the lock is active, then the session of the new transaction asks to be notified when the lock is released; otherwise, the new transaction acquires the lock.

The characteristics of `INSERT`, `UPDATE`, `DELETE`, and `SELECT ... FOR UPDATE` statements are as follows:

- A transaction containing a DML statement acquires exclusive row locks on the rows modified by the statement. Therefore, other transactions cannot update or delete the locked rows until the locking transaction either commits or rolls back.
- In addition to these row locks, a transaction containing a DML statement that modifies data also requires at least a subexclusive table lock (SX) on the table that contains the affected rows. If the transaction already holds an S, SRX, or X table lock for the table, which are more restrictive than an SX lock, then the SX lock is not needed and is not acquired. If the containing transaction already holds only an SS lock, however, then Oracle Database automatically converts the SS lock to an SX lock.
- A transaction that contains a DML statement does not require row locks on any rows selected by a subquery or an implicit query.

In the following sample `UPDATE` statement, the `SELECT` statement in parentheses is a subquery, whereas the `WHERE a > 5` clause is an implicit query:

```
UPDATE t SET x = ( SELECT y FROM t2 WHERE t2.z = t.z ) WHERE a > 5;
```

A subquery or implicit query inside a DML statement is guaranteed to be consistent as of the start of the query and does not see the effects of the DML statement of which it forms a part.

- A query in a transaction can see the changes made by previous DML statements in the same transaction, but not the uncommitted changes of other transactions.

 **See Also:**

*Oracle Database Concepts* for information on locks in foreign keys

## Automatic Locks in DDL Operations

A **data dictionary (DDL) lock** protects the definition of a schema object while it is acted upon or referred to by an ongoing DDL operation. For example, when a user creates a procedure, Oracle Database automatically acquires DDL locks for all schema objects referenced in the procedure definition. The DDL locks prevent these objects from being altered or dropped before procedure compilation is complete.

Oracle Database acquires a DDL lock automatically on behalf of any DDL transaction requiring it. Users cannot explicitly request DDL locks. Only individual schema objects that are modified or referenced are locked during DDL operations. The whole data dictionary is never locked.

DDL operations also acquire DML locks on the schema object to be modified.

## Exclusive DDL Locks

An **exclusive DDL lock** prevents other session from obtaining a DDL or DML lock.

Most DDL operations require exclusive DDL locks to prevent destructive interference with other DDL operations that might modify or reference the same schema object. For example, a `DROP TABLE` operation is not allowed to drop a table while an `ALTER TABLE` operation is adding a column to it, and vice versa. However, a query against the table is not blocked.

Exclusive DDL locks last for the duration of DDL statement execution and automatic commit. During the acquisition of an exclusive DDL lock, if another DDL lock is already held on the schema object by another operation, then the acquisition waits until the older DDL lock is released and then proceeds.

## Share DDL Locks

A **share DDL lock** for a resource prevents destructive interference with conflicting DDL operations, but allows data concurrency for similar DDL operations.

For example, when a `CREATE PROCEDURE` statement is run, the containing transaction acquires share DDL locks for all referenced tables. Other transactions can concurrently create procedures that reference the same tables and acquire concurrent share DDL locks on the same tables, but no transaction can acquire an exclusive DDL lock on any referenced table.

A share DDL lock lasts for the duration of DDL statement execution and automatic commit. Thus, a transaction holding a share DDL lock is guaranteed that the definition of the referenced schema object is constant for the duration of the transaction.

## Breakable Parse Locks

A **parse lock** is held by a SQL statement or PL/SQL program unit for each schema object that it references. Parse locks are acquired so that the associated shared SQL area can be invalidated if a referenced object is altered or dropped. A parse lock is called a **breakable parse lock** because it does not disallow any DDL operation and can be broken to allow conflicting DDL operations.

A **parse lock** is acquired in the shared pool during the parse phase of SQL statement execution. The lock is held as long as the shared SQL area for that statement remains in the shared pool.

## Manual Data Locking

Oracle Database always performs locking automatically to ensure data concurrency, data integrity, and statement-level read consistency. However, you can override the Oracle default locking mechanisms. This can be useful in situations such as the following:

- When your application requires consistent data for the duration of the transaction, not reflecting changes by other transactions, you can achieve transaction-level read consistency by using explicit locking, read-only transactions, serializable transactions, or by overriding default locking.
- When your application requires that a transaction have exclusive access to a resource so that the transaction does not have to wait for other transactions to complete, you can explicitly lock the data for the duration of the transaction.

You can override automatic locking at two levels:

- **Transaction.** You can override transaction-level locking with the following SQL statements:
  - SET TRANSACTION ISOLATION LEVEL
  - LOCK TABLE
  - SELECT ... FOR UPDATE
- **Session.** A session can set the required transaction isolate level with an ALTER SESSION SET ISOLATION LEVEL statement.

 **Note:**

When overriding Oracle default locking, the database administrator or application developer should ensure that data integrity is guaranteed, data concurrency is acceptable, and deadlocks are not possible or, if possible, are appropriately handled. For more information on these criteria, see *Oracle Database Concepts*.

# Oracle and Standard SQL

This appendix declares Oracle's conformance to the SQL standards established by the American National Standards Institute (ANSI) and the International Organization for Standardization (ISO).

The ISO SQL standard consists of nine parts (SQL/Framework, SQL/Foundation, SQL/CLI, SQL/PSM, SQL/MED, SQL/OLB, SQL/Schemata, SQL/JRT, and SQL/XML). The ANSI SQL standard consists of the same nine parts.

The mandatory portion of SQL is known as Core SQL and is found in SQL:2016 Part 2 (Foundation) and Part 11 (Schemata). The Foundation features are analyzed in Annex F of Part 2 in the table "Feature taxonomy and definition for mandatory features." The Schemata features are analyzed in Annex F of Part 11 in the table "Feature taxonomy and definition for mandatory features."

This appendix contains the following sections:

- [ANSI Standards](#)
- [ISO Standards](#)
- [Oracle Compliance to Core SQL](#)
- [Oracle Support for Optional Features of SQL/Foundation](#)
- [Oracle Compliance with SQL/CLI](#)
- [Oracle Compliance with SQL/PSM](#)
- [Oracle Compliance with SQL/MED](#)
- [Oracle Compliance with SQL/OLB](#)
- [Oracle Compliance with SQL/JRT](#)
- [Oracle Compliance with SQL/XML](#)
- [Oracle Compliance with FIPS 127-2](#)
- [Oracle Extensions to Standard SQL](#)
- [Oracle Compliance with Older Standards](#)
- [Character Set Support](#)

## ANSI Standards

The following documents of the American National Standards Institute (ANSI) relate to SQL:

- INCITS/ANSI/ISO/IEC 9075-1:2016, Information technology—Database languages—SQL—Part 1: Framework (SQL/Framework)
- INCITS/ANSI/ISO/IEC 9075-2:2016, Information technology—Database languages—SQL—Part 2: Foundation (SQL/Foundation)
- INCITS/ANSI/ISO/IEC 9075-3:2016, Information technology—Database languages—SQL—Part 3: Call-Level Interface (SQL/CLI)

- INCITS/ANSI/ISO/IEC 9075-4:2016, Information technology—Database languages—SQL—Part 4: Persistent Stored Modules (SQL/PSM)
- INCITS/ANSI/ISO/IEC 9075-9:2016, Information technology—Database languages—SQL—Part 9: Management of External Data (SQL/MED)
- INCITS/ANSI/ISO/IEC 9075-10:2016, Information technology—Database languages—SQL—Part 10: Object Language Bindings (SQL/OLB)
- INCITS/ANSI/ISO/IEC 9075-11:2016, Information technology—Database languages—SQL—Part 11: Information and Definition Schemas (SQL/Schemata)
- INCITS/ANSI/ISO/IEC 9075-13:2016, Information technology—Database languages—SQL—Part 13: SQL Routines and Types using the Java Programming Language (SQL/JRT)
- INCITS/ANSI/ISO/IEC 9075-14:2016, Information technology—Database languages—SQL—Part 14: XML-Related Specifications (SQL/XML)

These standards are identical to the corresponding ISO standards listed in the next section.

You can obtain a copy of ANSI standards from this address:

American National Standards Institute

## Oracle Compliance to Core SQL

The ANSI and ISO SQL standards require conformance claims to state the type of conformance and the implemented facilities. The minimum claim of conformance is called Core SQL and is defined in Part 2, SQL/Foundation, and Part 11, SQL/Schemata, of the standard. The following products provide full or partial conformance with Core SQL as described in the tables that follow:

- Oracle Database server, release 12.2
- OTT (Oracle Type Translator), release 12.2
- Pro\*C/C++, release 12.2
- Pro\*COBOL, release 12.2

The SQL standards conformance features can be used either as a guide to portability, or as a guide to functionality. From the standpoint of portability, the user is interested in conformance to both the precise syntax and semantics of the standard feature. From the standpoint of functionality, the user is less concerned about the precise syntax and more concerned with issues of semantics. The tables in this appendix use the following terms regarding support for standard syntax and semantics:

- Full Support: The feature is supported with standard syntax and semantics.
- Partial Support: Some, but not all, of the standard syntax is supported; whatever is supported has standard semantics.
- Enhanced Support: The standard semantics is supported, as well as additional functionality.
- Equivalent Support: The standard semantics is supported using non-standard syntax.
- Similar Support: Neither the standard's syntax nor semantics are supported precisely, but similar functionality is provided.

Oracle's support for the features of Core SQL is listed in [Table C-1](#):

**Table C-1 Oracle Support of Core SQL Features**

| Feature ID,<br>Feature                | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| E011, Numeric<br>data types           | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| E061, Basic predicates and search conditions | Oracle fully supports this feature, except that Oracle comparison of character strings differs from the standard as follows: In the standard, two character strings of unequal length are compared by either padding the shorter string with spaces or a fictitious character that is less than all actual characters. The decision on padding is made on the basis of the character set. In Oracle, the decision is based on whether the comparands are of fixed or varying length.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| E071, Basic query expressions                | Oracle fully supports the following subfeatures: <ul style="list-style-type: none"> <li>• E071-01, UNION DISTINCT table operator</li> <li>• E071-02, UNION ALL table operator</li> <li>• E071-05, Columns combined by table operators need not have exactly the same type</li> <li>• E071-06, table operators in subqueries</li> </ul> Oracle has equivalent functionality for the following subfeature: <ul style="list-style-type: none"> <li>• E071-03, EXCEPT DISTINCT table operator: Use MINUS instead of EXCEPT DISTINCT</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                      |
| E081, Basic privileges                       | Oracle fully supports all subfeatures of this feature, except E081-09, USAGE privileges. In the standard, the USAGE privilege permits the user to use domains, collations, character sets, transliterations, user-defined types and sequence generators. Oracle does not support domains or transliterations. No privileges are required to access collations and character sets. The Oracle privilege to use a user-defined type is EXECUTE. The Oracle privilege to use a sequence type is SELECT.                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| E091, Set functions                          | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| E101, Basic data manipulation                | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| E111, Single row SELECT statement            | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| E121, Basic cursor support                   | Oracle fully supports the following subfeatures: <ul style="list-style-type: none"> <li>• E121-02, ORDER BY columns need not be in SELECT list</li> <li>• E121-03, Value expressions in ORDER BY clause</li> <li>• E121-04, OPEN statement</li> <li>• E121-06, Positioned UPDATE statement</li> <li>• E121-07, Positioned DELETE statement</li> <li>• E121-08, CLOSE statement</li> </ul> Oracle provides partial support for the following subfeatures: <ul style="list-style-type: none"> <li>• E121-01, DECLARE CURSOR - fully supported, except for the FOR READ ONLY syntax</li> <li>• E121-10 FETCH statement, implicit NEXT - fully supported, except for the noise word FROM</li> </ul> Oracle provides enhanced support for the following subfeature: <ul style="list-style-type: none"> <li>• E121-17, WITH HOLD cursors (in the standard, a cursor is not held through a ROLLBACK, but Oracle does hold through ROLLBACK)</li> </ul> |

| F812, Basic flagging                                  | Oracle has a flagger, but it flags SQL-92 compliance rather than SQL:2011 compliance.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| S011, Distinct types                                  | Distinct types are strongly typed scalar types. A distinct type can be emulated in Oracle using an object type with only one attribute. The standard's Information Schema view called <code>USER_DEFINED_TYPES</code> is equivalent to Oracle's metadata view <code>ALL_TYPES</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| T321, Basic SQL-invoked routines                      | <p>Oracle fully supports these subfeatures:</p> <ul style="list-style-type: none"> <li>• T321-03, function invocation</li> <li>• T321-04, <code>CALL</code> statement</li> </ul> <p>Oracle supports these subfeatures with syntactic differences:</p> <ul style="list-style-type: none"> <li>• T321-01, user-defined functions with no overloading</li> <li>• T321-02, user-defined procedures with no overloading</li> </ul> <p>The Oracle syntax for <code>CREATE FUNCTION</code> and <code>CREATE PROCEDURE</code> differs from the standard as follows:</p> <ul style="list-style-type: none"> <li>• In the standard, the mode of a parameter (<code>IN</code>, <code>OUT</code>, or <code>INOUT</code>) comes before the parameter name, whereas in Oracle it comes after the parameter name.</li> <li>• The standard uses <code>INOUT</code>, whereas Oracle uses <code>IN OUT</code>.</li> <li>• Oracle requires either <code>IS</code> or <code>AS</code> after the return type and before the definition of the routine body, while the standard lacks these keywords.</li> <li>• If the routine body is in C (for example), then the standard uses the keywords <code>LANGUAGE C EXTERNAL NAME</code> to name the routine, whereas Oracle uses <code>LANGUAGE C NAME</code>.</li> <li>• If the routine body is in SQL, then Oracle uses its proprietary procedural extension called PL/SQL.</li> </ul> <p>Oracle supports the following subfeature in PL/SQL but not in Oracle SQL:</p> <ul style="list-style-type: none"> <li>• T321-05, <code>RETURN</code> statement</li> </ul> <p>Oracle provides equivalent functionality for the following subfeatures:</p> <ul style="list-style-type: none"> <li>• T321-06, <code>ROUTINES</code> view: Use the <code>ALL PROCEDURES</code> metadata view.</li> <li>• T321-07, <code>PARAMETERS</code> view: Use the <code>ALL_ARGUMENTS</code> and <code>ALL_METHOD_PARAMS</code> metadata views.</li> </ul> |
| T631, <code>IN</code> predicate with one list element | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Oracle Support for Optional Features of SQL/Foundation

Oracle's support for optional features of SQL/Foundation is listed in [Table C-2](#):

**Table C-2 Oracle Support for Optional Features of SQL/Foundation**

| Feature ID, Feature          | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| B012, Embedded C             | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| B013, Embedded COBOL         | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| B021, Direct SQL             | Oracle fully supports this feature, as SQL*Plus.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| B031, Basic dynamic SQL      | <p>Oracle supports dynamic SQL in two styles, documented in the embedded language manuals as "Oracle dynamic SQL" and "ANSI dynamic SQL."</p> <p>ANSI dynamic SQL is an implementation of the standard, with the following restrictions:</p> <ul style="list-style-type: none"> <li>• Oracle supports a subset of the descriptor items.</li> <li>• For &lt;input using clause&gt;, Oracle only supports &lt;using input descriptor&gt;.</li> <li>• For &lt;output using clause&gt;, Oracle only supports &lt;into descriptor&gt;.</li> <li>• Dynamic parameters are indicated by a colon followed by an identifier rather than a question mark.</li> </ul> <p>Oracle dynamic SQL is similar to standard dynamic SQL, with the following modifications:</p> <ul style="list-style-type: none"> <li>• Parameters are indicated by a colon followed by an identifier, instead of a question mark.</li> <li>• Oracle's DESCRIBE SELECT LIST FOR statement replaces the standard's DESCRIBE OUTPUT.</li> <li>• Oracle provides DECLARE STATEMENT if you want to declare a cursor using a dynamic SQL statement physically prior to the PREPARE statement that prepares the dynamic SQL statement.</li> </ul> |
| B032, Extended dynamic SQL   | <p>In ANSI dynamic SQL, Oracle only implements the ability to declare global statements and global cursors from this feature; the rest of the feature is not supported.</p> <p>In Oracle dynamic SQL, Oracle's DESCRIBE BIND VARIABLES is equivalent to the standard's DESCRIBE INPUT; the rest of this feature is not supported.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| B122, Routine language C     | Oracle supports external routines written in C, though Oracle does not support the standard syntax for creating such routines.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| B128, Routine language SQL   | Oracle supports routines written in PL/SQL, which is Oracle's equivalent to the standard procedural language SQL/PSM.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| F032, CASCADE drop behavior  | In Oracle, a DROP command invalidates all of the dropped object's dependent objects. Invalidated objects are effectively unusable until the dropped object is redefined in such a way to allow successful recompilation of the invalidated object.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| F033, ALTER TABLE statement: | Oracle provides a DROP COLUMN clause, but without the RESTRICT or CASCADE options found in the standard.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation**

| Feature ID, Feature                            | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F034, Extended REVOKE statement                | <p>Oracle supports the following parts of this feature:</p> <ul style="list-style-type: none"> <li>• F034-01, REVOKE statement performed by other than the owner of a schema object</li> <li>• F034-03, REVOKE statement to revoke a privilege that the grantee has WITH GRANT OPTION</li> </ul> <p>Oracle provides equivalent functionality for the following parts of this feature:</p> <ul style="list-style-type: none"> <li>• CASCADE: In Oracle, a REVOKE invalidates all dependent objects, which become effectively unusable until the metadata is changed through subsequent CREATE and GRANT commands enabling the invalidated object to be successfully recompiled.</li> </ul> |
| F052, Intervals and datetime arithmetic        | Oracle only supports the INTERVAL YEAR TO MONTH and INTERVAL DAY TO SECOND data types.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| F111, Isolation levels other than SERIALIZABLE | In addition to SERIALIZABLE, Oracle supports the READ COMMITTED isolation level.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| F121, Basic diagnostics management             | Much of the functionality of this feature is provided through the SQLCA in embedded languages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| F191, Referential delete actions               | Oracle supports ON DELETE CASCADE and ON DELETE SET NULL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| F200, TRUNCATE TABLE                           | Oracle fully supports this feature, and extends it by permitting truncation of a table that references itself in a referential integrity constraint, and the ability to cascade to child tables with enabled ON DELETE CASCADE referential constraints.                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| F231, Privilege tables                         | <p>Oracle makes this information available in the following metadata views:</p> <ul style="list-style-type: none"> <li>• Instead of TABLE_PRIVILEGES, use ALL_TAB_PRIVS.</li> <li>• Instead of COLUMN_PRIVILEGES, use ALL_COL_PRIVS.</li> <li>• Oracle does not support USAGE privileges so there is no equivalent to USAGE_PRIVILEGES.</li> </ul>                                                                                                                                                                                                                                                                                                                                        |
| F281, LIKE enhancements                        | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| F291, UNIQUE predicate                         | <p>The IS A SET condition may be used to test whether a multiset is a set; that is, each row is unique. Thus, the equivalent of</p> <pre>UNIQUE &lt;table subquery&gt;</pre> <p>is</p> <pre>CAST (&lt;table subquery&gt; AS MULTISET) IS A SET</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| F302, INTERSECT table operator                 | Syntactically, Oracle differs from the standard in that UNION, INTERSECT, and MINUS have the same precedence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation**

| Feature ID, Feature                      | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F312, MERGE statement                    | The Oracle MERGE statement is almost the same as the standard, with these exceptions: <ul style="list-style-type: none"> <li>• Oracle does not support the optional AS keyword before a table alias.</li> <li>• Oracle does not support the ability to rename columns of the table specified in the USING clause with a parenthesized list of column names following the table alias.</li> <li>• Oracle does not support the &lt;override clause&gt;.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                     |
| F314, MERGE statement with DELETE branch | Oracle has similar functionality, though in Oracle you must first update a row, after which you can delete it if the revised row meets a condition.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| F321, User authorization                 | Oracle provides equivalent functionality for the following subfeatures: <ul style="list-style-type: none"> <li>• Use SYS_CONTEXT ('USERENV', 'SESSION_USER') instead of SESSION_USER</li> <li>• Use SYS_CONTEXT ('USERENV', 'CURRENT_USER') instead of CURRENT_USER</li> </ul> Oracle does not support the following subfeatures: <ul style="list-style-type: none"> <li>• SYSTEM_USER</li> <li>• SET SESSION AUTHORIZATION statement</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                     |
| F341, Usage tables                       | Oracle makes this information available in the views ALL_DEPENDENCIES, DBA_DEPENDENCIES, and USER_DEPENDENCIES.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| F381, Extended schema manipulation       | Oracle fully supports the following element of this feature: <ul style="list-style-type: none"> <li>• Oracle supports the standard syntax to add a table constraint using ALTER TABLE.</li> </ul> Oracle partially supports the following element of this feature: <ul style="list-style-type: none"> <li>• Oracle supports the standard syntax to drop a table constraint, except that Oracle does not support RESTRICT.</li> </ul> Oracle provides equivalent functionality for the following element of this feature: <ul style="list-style-type: none"> <li>• To alter the default value of a column, use the MODIFY option of ALTER TABLE.</li> </ul> Oracle does not support the following parts of this feature: <ul style="list-style-type: none"> <li>• DROP SCHEMA statement</li> <li>• ALTER ROUTINE statement</li> </ul> |
| F382, Alter column data type             | Oracle supports this functionality, though with non-standard syntax. As an extension to the standard, Oracle allows you to reduce the size or precision of a column.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| F383, Set column not null clause         | Oracle provides equivalent functionality for the two subfeatures of this feature: <ul style="list-style-type: none"> <li>• To add a NOT NULL constraint to an existing column, use ALTER TABLE ... MODIFY</li> <li>• To drop a NOT NULL constraint, use ALTER TABLE to drop the constraint by name</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| F384, Drop identity property clause      | Oracle provides equivalent functionality using ALTER TABLE ... MODIFY (... DROP IDENTITY)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation**

| Feature ID, Feature                                     | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F386, Set identity column generation clause             | Oracle provides equivalent functionality. Oracle's syntax and semantics are the same as the standard, with this exception: <ul style="list-style-type: none"> <li>• Oracle does not support RESTART; use START WITH instead. When restarting an identity column, the values of the other parameters for the identity column are reset to their defaults unless explicitly set in the ALTER TABLE statement.</li> </ul> Oracle's START WITH LIMIT VALUE option is an extension on the standard.                                                                                                                       |
| F391, Long identifiers                                  | Oracle supports identifiers up to 128 characters in length.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| F393, Unicode escapes in literals                       | The Oracle UNISTR function supports numeric escape sequences for all Unicode characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| F394, Optional normal form specification                | This feature adds the keywords NFC, NFD, NFKC, and NKD to the NORMALIZE function and the IS NORMAL predicate. Without these keywords, NFC is the default (see Feature T061, UCS support). Oracle supports all four normalization forms, with nonstandard syntax, as follows: <ul style="list-style-type: none"> <li>• For NFC, use COMPOSE</li> <li>• For NFD, use DECOMPOSE with the CANONICAL option</li> <li>• For NFKD, use DECOMPOSE with the COMPATIBILITY option</li> <li>• For NFKC, use DECOMPOSE with the CANONICAL option followed by COMPOSE</li> </ul> Oracle does not support the IS NORMAL predicate. |
| F401, Extended joined table                             | Oracle supports FULL outer joins, CROSS joins, and NATURAL joins.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| F402, Named column joins for LOBs, arrays and multisets | Oracle supports named column joins for columns whose declared type is nested table. Oracle does not support named column joins for LOBs or arrays.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| F403, Partitioned join tables                           | Oracle supports this feature, except with FULL outer joins.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| F411, Time zone specification                           | Oracle fully supports TIMESTAMP WITH TIME ZONE, but does not support TIME WITH TIME ZONE.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| F421, National character                                | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| F431, Read-only scrollable cursors                      | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| F441, Extended set function support                     | Oracle supports the following parts of this feature: <ul style="list-style-type: none"> <li>• The ability in the WHERE clause to reference a column that is defined using an aggregate, either in a view or an inline view</li> <li>• COUNT without DISTINCT of an expression</li> <li>• Aggregates that reference columns that are outer references with respect to the aggregating query. However, Oracle defines the aggregating query as the innermost query containing the aggregate, rather than the innermost query that defines a range variable referenced in the aggregate.</li> </ul>                     |
| F442, Mixed column references in set functions          | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| F461, Named character sets                              | Oracle supports many character sets with Oracle-defined names. Oracle does not support any other aspect of this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation**

| Feature ID, Feature                             | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F491, Constraint management                     | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| F492, Optional table constraint enforcement     | ENFORCED in the standard is equivalent to ENABLE VALIDATE in Oracle. NOT ENFORCED in the standard is equivalent to DISABLE NOVALIDATE in Oracle. Other combinations of the ENABLE   DISABLE, VALIDATE   NOVALIDATE, and RELY   NORELY options are extensions of the standard.                                                                                                                                                                                  |
| F531, Temporary tables                          | Oracle supports GLOBAL TEMPORARY tables.                                                                                                                                                                                                                                                                                                                                                                                                                       |
| F555, Enhanced seconds precision                | Oracle provides enhanced support for this feature, supporting up to 9 places after the decimal point.                                                                                                                                                                                                                                                                                                                                                          |
| F561, Full value expressions                    | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| F571, Truth value tests                         | Oracle's LNNVL function is equivalent to the standard's IS NOT TRUE predicate.                                                                                                                                                                                                                                                                                                                                                                                 |
| F591, Derived tables                            | Oracle supports <derived table>, with the exception of: <ul style="list-style-type: none"> <li>• Oracle does not support the optional AS keyword before a table alias.</li> <li>• Oracle does not support &lt;derived column list&gt;.</li> </ul>                                                                                                                                                                                                              |
| F641, Row and table constructors                | In Oracle, a row constructor may be used in an equality or inequality comparison with another row constructor or with a subquery. Oracle does not support anything else in this feature.                                                                                                                                                                                                                                                                       |
| F690, Collation support                         | Oracle's NLSSORT function may be used to change the collation of character expressions.                                                                                                                                                                                                                                                                                                                                                                        |
| F693, SQL-sessions and client module collations | To set a session collation, use ALTER SESSION SET NLS_COMP = 'LINGUISTIC' and also set NLS_SORT to your desired collation. Oracle does not support client module collations.                                                                                                                                                                                                                                                                                   |
| F695, Translation support                       | The Oracle CONVERT function can convert between the database character set and the national character set. For other character sets, store the data in the RAW data type and use the PL/SQL package function UTL_RAW.CONVERT. Oracle does not provide the ability to add or drop character set conversions.                                                                                                                                                    |
| F721, Deferrable constraints                    | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| F731, INSERT column privileges                  | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| F761, Session management                        | Oracle provides the following equivalents for elements of this feature: <ul style="list-style-type: none"> <li>• The equivalent to the standard's SET SESSION CHARACTERISTICS AS TRANSACTION SERIALIZABLE is ALTER SESSION SET ISOLATION_LEVEL = SERIALIZABLE.</li> <li>• The equivalent to the standard's SET SCHEMA is ALTER SESSION SET CURRENT_SCHEMA.</li> <li>• The equivalent to the standard's SET COLLATION is ALTER SESSION SET NLS_SORT.</li> </ul> |
| F763, CURRENT_SCHEMA                            | Oracle's equivalent is SYS_CONTEXT ('USERENV', 'CURRENT_SCHEMA')                                                                                                                                                                                                                                                                                                                                                                                               |

**Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation**

| Feature ID, Feature                                          | Support                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| F771, Connection management                                  | Oracle's CONNECT statement provides the same functionality as the standard's CONNECT statement, though with different syntax. Instead of using the standard's SET CONNECTION, Oracle provides the AT clause to indicate which connection a SQL statement should be performed on. Oracle embedded languages let you disconnect from a connection by using the RELEASE option of either COMMIT or ROLLBACK. |
| F781, Self-referencing operations                            | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                       |
| F801, Full set function                                      | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                       |
| F831, Full cursor update                                     | Oracle supports the combination of FOR UPDATE and ORDER BY clauses in a query.                                                                                                                                                                                                                                                                                                                            |
| F841, LIKE_REGEX predicate                                   | Oracle's equivalent is REGEXP_LIKE. Oracle's pattern syntax lacks some of the features of the standard's. Oracle's match parameter has the same capabilities as the standard's, though with a few spelling differences.                                                                                                                                                                                   |
| F842, OCCURRENCES_REGEX function                             | Oracle's equivalent is REGEXP_COUNT. Oracle's pattern syntax lacks some of the features of the standard's. Oracle's match parameter has the same capabilities as the standard's, though with a few spelling differences.                                                                                                                                                                                  |
| F843, POSITION_REGEX function                                | Oracle's equivalent is REGEXP_INSTR. Oracle's pattern syntax lacks some of the features of the standard's. Oracle's match parameter has the same capabilities as the standard's, though with a few spelling differences.                                                                                                                                                                                  |
| F844, SUBSTRING_REGEX function                               | Oracle's equivalent is REGEXP_SUBSTR. Oracle's pattern syntax lacks some of the features of the standard's. Oracle's match parameter has the same capabilities as the standard's, though with a few spelling differences.                                                                                                                                                                                 |
| F845, TRANSLATE_REGEX function                               | Oracle's equivalent is REGEXP_REPLACE. Oracle's pattern syntax lacks some of the features of the standard's. Oracle's match parameter has the same capabilities as the standard's, though with a few spelling differences.                                                                                                                                                                                |
| F850, Top-level <order by clause> in <query expression>      | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                       |
| F851, <order by clause> in subqueries                        | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                       |
| F852, Top-level <order by clause> in views                   | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                       |
| F855, Nested <order by clause> in <query expression>         | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                       |
| F856, Nested <fetch first clause> in <query expression>      | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                       |
| F857, Top-level <fetch first clause> in a <query expression> | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                       |

| Feature ID, Feature                    | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| S043, Enhanced reference types         | Oracle supports the following elements of this feature: <ul style="list-style-type: none"> <li>• DEREF operator to return the object referenced by a reference</li> <li>• SCOPE clause as a constraint on columns of tables or materialized views</li> <li>• Adding and dropping the scope of a column</li> <li>• References that are either system-generated or derived from the primary key (but not from any other list of columns, nor from a list of attributes of the type)</li> </ul>                                                                                                                  |
| S051, Create table of type             | Oracle's object tables are equivalent to tables of structured type in the standard.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| S081, Subtables                        | Oracle supports hierarchies of object views, but not of object base tables. To emulate a hierarchy of base tables, create a hierarchy of views on those base tables.                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| S091, Basic array support              | Oracle VARRAY types are equivalent to array types in the standard. However, Oracle does not support storage of arrays of LOBs. To access a single element of an array using a subscript, you must use PL/SQL. Oracle supports the following aspects of this feature with nonstandard syntax: <ul style="list-style-type: none"> <li>• To construct an instance of varray type, including an empty array, use the varray type constructor.</li> <li>• To unnest a varray in the FROM clause, use the TABLE operator.</li> <li>• To get the cardinality of a varray, use the COUNT method in PL/SQL.</li> </ul> |
| S092, Arrays of user-defined types     | Oracle supports VARRAYS of object types.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| S094, Arrays of reference types        | Oracle supports VARRAYS of references.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| S095, Array constructors by query      | Oracle supports this using CAST (MULTISET (SELECT ...) AS varray_type). The ability to order the elements of the array using ORDER BY is not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| S097, Array element assignment         | In PL/SQL, you can assign to array elements, using syntax that is similar to the standard (SQL/PSM).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| S098, ARRAY_AGG                        | Oracle does not have an aggregate that results in a varray. Instead, the COLLECT aggregate may be used to create a multiset, which can be cast to an array of the element type.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| S111, ONLY in query expressions        | Oracle supports the ONLY clause for view hierarchies; Oracle does not support hierarchies of base tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| S151, Type predicate                   | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| S161, Subtype treatment                | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| S162, Subtype treatment for references | Supported, with a minor syntactic difference: The standard requires parentheses around the referenced type's name; Oracle does not support parentheses in this position.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| S201, SQL-invoked routines on arrays   | PL/SQL provides the ability to pass arrays as parameters and return arrays as the result of functions. Procedures and functions written in C may pass arrays and return arrays as the result of functions using the Oracle Type Translator (OTT).                                                                                                                                                                                                                                                                                                                                                             |

**Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation**

| Feature ID, Feature                     | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| S202, SQL-invoked routines on multisets | A PL/SQL routine may have nested tables as parameters, and may return a nested table. Routines written in C may pass arrays and return arrays as the result of functions using the Oracle Type Translator.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| S232, Array locators                    | Oracle Type Translator supports descriptors for arrays, which achieve the same purpose as locators.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| S233, Multiset locators                 | Oracle supports locators for nested tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| S241, Transform functions               | The Oracle Type Translator provides the same capability as transforms.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| S251, User-defined orderings            | Oracle's object type ordering capabilities correspond to the standard's capabilities as follows: <ul style="list-style-type: none"> <li>• Oracle's MAP ordering corresponds to the standard's ORDER FULL BY MAP ordering.</li> <li>• Oracle's ORDER ordering corresponds to the standard's ORDER FULL BY RELATIVE ordering.</li> <li>• If an Oracle object type has neither MAP nor ORDER declared, then this corresponds to EQUALS ONLY BY STATE in the standard.</li> <li>• Oracle does not have unordered object types; you can alter the ordering but you cannot drop it.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| S261, Specified type method             | The GetTypeName method of the ANYDATA type may be used to learn the name of a type.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| S271, Basic multiset support            | Multisets in the standard are supported as nested table types in Oracle. The Oracle nested table data type based on a scalar type ST is equivalent, in standard terminology, to a multiset of rows having a single field of type ST and named <i>column_value</i> . The Oracle nested table type based on an object type is equivalent to a multiset of structured type in the standard.<br><br>Oracle supports the following elements of this feature on nested tables using the same syntax as the standard has for multisets: <ul style="list-style-type: none"> <li>• The CARDINALITY function</li> <li>• The SET function</li> <li>• The MEMBER predicate</li> <li>• The IS A SET predicate</li> <li>• The COLLECT aggregate</li> </ul> All other aspects of this feature are supported with non-standard syntax, as follows: <ul style="list-style-type: none"> <li>• To create an empty multiset, denoted MULTISET[] in the standard, use an empty constructor of the nested table type.</li> <li>• To obtain the sole element of a multiset with one element, denoted ELEMENT (&lt;multiset value expression&gt;) in the standard, use a scalar subquery to select the single element from the nested table.</li> <li>• To construct a multiset by enumeration, use the constructor of the nested table type.</li> <li>• To construct a multiset by query, use CAST with a multiset argument, casting to the nested table type.</li> <li>• To unnest a multiset, use the TABLE operator in the FROM clause.</li> </ul> |

| T042, Extended LOB support                           | <p>Oracle fully supports the following element of this feature:</p> <ul style="list-style-type: none"> <li>• TRIM function on a CLOB argument</li> </ul> <p>Oracle provides equivalent functionality for the following elements of this feature:</p> <ul style="list-style-type: none"> <li>• BLOB and CLOB substring, supported using SUBSTR</li> <li>• SIMILAR predicate, supported using REGEXP_LIKE to perform pattern matching with a Perl-like syntax</li> </ul> <p>The following elements of this feature are not supported:</p> <ul style="list-style-type: none"> <li>• Comparison predicates with BLOB or CLOB operands</li> <li>• CAST with a BLOB or CLOB operand</li> <li>• OVERLAY (This may be emulated using SUBSTR and string concatenation.)</li> <li>• LIKE predicate with BLOB or CLOB operands</li> </ul> |
| T051, Row types                                      | Oracle object types can be used in place of the standard's row types.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| T061, UCS support                                    | <p>Oracle provides equivalent functionality for the following elements of this feature:</p> <ul style="list-style-type: none"> <li>• Oracle supports the keyword CHAR instead of CHARACTERS, and BYTE instead of OCTETS, in a character data type declaration.</li> <li>• The Oracle COMPOSE function is equivalent to the standard's NORMALIZE function.</li> </ul> <p>Oracle does not support the IS NORMALIZED predicate.</p>                                                                                                                                                                                                                                                                                                                                                                                               |
| T071, BIGINT data type                               | On many implementations, BIGINT refers to a binary integer type with 64 bits, which supports almost 19 decimal digits. The Oracle NUMBER type supports 39 decimal digits.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| T111, Updatable joins, unions and columns            | Oracle's updatable join views are similar to the standard's updatable join capabilities. Unlike the standard, Oracle does not require an updatable join view to display the strong candidate key in the SELECT list. Although an updatable join view might have more than one key-preserved table, only one of them may be modified using an UPDATE or DELETE, unlike the standard, which modifies all key-preserved tables of an updatable join.                                                                                                                                                                                                                                                                                                                                                                              |
| T121, WITH (excluding RECURSIVE) in query expression | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| T122, WITH (excluding RECURSIVE) in subquery         | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| T131, Recursive query                                | Oracle supports the use of a WITH clause element that references itself, but without the RECURSIVE keyword. Alternatively, Oracle's START WITH and CONNECT BY clauses can be used to perform many recursive queries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| T132, Recursive query in subquery                    | Oracle supports the use of a WITH clause element that references itself, but without the RECURSIVE keyword. Alternatively, Oracle's START WITH and CONNECT BY clauses can be used to perform many recursive queries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| T141, SIMILAR predicate                              | Oracle provides REGEXP_LIKE for pattern matching with a Perl-like syntax.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation**

| Feature ID, Feature                           | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| T172, AS subquery clause in table definition  | Oracle's AS subquery feature of CREATE TABLE has substantially the same functionality as the standard, though there are some syntactic differences.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| T174, Identity columns                        | <p>Oracle supports this feature, with the following syntactic differences:</p> <ul style="list-style-type: none"> <li>• Oracle uses NOMINVALUE and NOMAXVALUE instead of the standard's NO MINVALUE and NO MAXVALUE.</li> <li>• To restart an identity column, in an ALTER TABLE MODIFY statement, use START WITH LIMIT VALUE to restart at the highest value (for an increasing identity column) or the lowest value (for a decreasing identity column); use START WITH number to restart at a specific number.</li> </ul> <p>GENERATED BY DEFAULT ON NULL is an Oracle extension.</p>                                                                                                                                   |
| T175, Generated columns                       | <p>Oracle supports this feature, with the following restrictions:</p> <ul style="list-style-type: none"> <li>• Generated columns are not supported in temporary tables.</li> <li>• The data type of a generated column may not be LOB or XML.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| T176, Sequence generator support              | Oracle's sequences have the same capabilities as the standard's, though with different syntax.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| T178, Identity columns: simple restart option | Oracle's START WITH LIMIT VALUE is the same as the standard's simple restart if the identity column has not cycled.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| T180, System-versioned tables                 | <p>Oracle's Flashback capability is substantially the same as the standard's system-versioned tables. Some key differences are:</p> <ul style="list-style-type: none"> <li>• In Oracle you do not need to designate particular tables for journaling; all tables are journaled.</li> <li>• In Oracle, LOB columns need to be individually designated for journaling, because of the potential for large amounts of data. The standard has no analogous provision.</li> <li>• In Oracle you need a privilege in order to read historical data.</li> <li>• In the standard, journaled tables have columns to record the start and end timestamps for the row. In Oracle, this is provided through pseudocolumns.</li> </ul> |

| T181, Application-time period tables                    | <p>Oracle supports the following elements of this feature:</p> <ul style="list-style-type: none"> <li>• Application-time period definition during <code>CREATE TABLE</code></li> <li>• Adding and dropping an application-time period definition using <code>ALTER TABLE</code> with a minor syntactic difference: Oracle requires parentheses around the period specification; the standard does not support parentheses in this position.</li> </ul> <p>Oracle extends this feature:</p> <ul style="list-style-type: none"> <li>• With the ability to have more than one application-time period per table.</li> <li>• By making the start time and end time columns optional. In this case, Oracle will create these columns implicitly.</li> <li>• By allowing <code>NULL</code> for the start time column to indicate that the row is considered valid for any point in time before the value of the end time column.</li> <li>• By allowing <code>NULL</code> for the end time column to indicate that the row is considered valid for any point in time on or after the value of the start time column.</li> <li>• By querying an application-time period table using the flashback query options <code>VERSIONS PERIOD FOR</code> and <code>AS OF PERIOD FOR</code>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                        |
| T201, Comparable data types for referential constraints | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| T211, Basic trigger capability                          | <p>Oracle's triggers differ from the standard as follows:</p> <ul style="list-style-type: none"> <li>• Oracle does not provide the optional syntax <code>FOR EACH STATEMENT</code> for the default case, the statement trigger.</li> <li>• Oracle does not support <code>OLD TABLE</code> and <code>NEW TABLE</code>; the transition tables specified in the standard (the multiset of before and after images of affected rows) are not available.</li> <li>• The trigger body is written in PL/SQL, which is functionally equivalent to the standard's procedural language PSM, but not the same.</li> <li>• In the trigger body, the new and old transition variables are referenced beginning with a colon.</li> <li>• Oracle's row triggers are executed as the row is processed, instead of buffering them and executing all of them after processing all rows. The standard's semantics are deterministic, but Oracle's in-flight row triggers are more performant.</li> <li>• Oracle's before-row and before-statement triggers can perform DML statements, which is forbidden in the standard. However, Oracle's after-row statements cannot perform DML, while it is permitted in the standard.</li> <li>• When multiple triggers apply, the standard says they are executed in order of definition. In Oracle the execution order is nondeterministic, unless specified using <code>FOLLOWS</code>.</li> <li>• Oracle uses the system privileges <code>CREATE TRIGGER</code> and <code>CREATE ANY TRIGGER</code> to regulate creation of triggers, instead of the standard's <code>TRIGGER</code> privilege, which is a table privilege.</li> </ul> |
| T212, Enhanced trigger capability                       | This feature permits statements triggers, which Oracle supports, as described for feature T211, Basic trigger capability.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

**Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation**

| Feature ID, Feature                                       | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T213, INSTEAD OF triggers                                 | Oracle supports INSTEAD OF triggers on views, with syntax and semantics agreeing with the standard except as noted for feature T211, Basic trigger capability. Oracle permits an INSTEAD OF trigger on a view that specified WITH CHECK OPTION, unlike the standard.                                                                                                                                                                                                                                                                                                                                                                                      |
| T241, START TRANSACTION statement                         | Oracle's SET TRANSACTION statement starts a transaction making it equivalent to the standard's START TRANSACTION rather than the standard's SET TRANSACTION. Oracle's READ ONLY transactions are at SERIALIZABLE isolation level.                                                                                                                                                                                                                                                                                                                                                                                                                         |
| T271, Savepoints                                          | Oracle supports this feature, except: <ul style="list-style-type: none"> <li>• Oracle does not support RELEASE SAVEPOINT.</li> <li>• Oracle does not support savepoint levels.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| T285, Enhanced derived column names                       | This feature pertains only to derived columns in a SELECT list with no column alias and consisting of a SQL parameter reference. In that case, the column name defaults to the parameter name, the same as in the standard.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| T323, Explicit security for external routines             | The Oracle syntax AUTHID { CURRENT USER   DEFINER } when used when creating an external function, procedure, or package is equivalent to the standard's EXTERNAL SECURITY { DEFINER   INVOKER }.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| T324, Explicit security for SQL routines                  | Oracle's syntax AUTHID { CURRENT USER   DEFINER } when used when creating a PL/SQL function, procedure, or package is equivalent to the standard's SQL SECURITY { DEFINER   INVOKER }.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| T325, Qualified SQL parameter reference                   | PL/SQL supports the use of a routine name to qualify a parameter name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| T326, Table functions                                     | Oracle provides equivalents for the following elements of this feature: <ul style="list-style-type: none"> <li>• &lt;multiset value constructor by query&gt; is supported using CAST (MULTISET (&lt;query expression&gt;) AS &lt;nested table type&gt;)</li> <li>• &lt;table function derived table&gt; is supported using the TABLE operator in the FROM clause with a varray or nested table as the argument</li> <li>• &lt;collection value expression&gt; is equivalent to an Oracle expression resulting in a varray or nested table</li> <li>• &lt;returns table type&gt; is equivalent to a PL/SQL function that returns a nested table</li> </ul> |
| T331, Basic roles                                         | Oracle supports this feature, except for REVOKE ADMIN OPTION FOR <role name>.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| T341, Overloading of SQL-invoked functions and procedures | Oracle supports overloading of functions and procedures. However, the rules for handling certain data type combinations are not the same as the standard. For example, the standard permits the coexistence of two functions of the same name differing only in the numeric types of the arguments, whereas Oracle does not permit this.                                                                                                                                                                                                                                                                                                                  |
| T351, Bracketed comments                                  | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| T431, Extended grouping capabilities                      | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation**

| Feature ID, Feature                                                      | Support                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T432, Nested and concatenated GROUPING SETS                              | Oracle supports concatenated GROUPING SETS, but not nested GROUPING SETS.                                                                                                                                                                                                                                                                    |
| T433, Multiargument function GROUPING                                    | The Oracle GROUP_ID function can be used to conveniently distinguish groups in a grouped query, serving the same purpose as the standard multiargument GROUPING function.                                                                                                                                                                    |
| T441, ABS and MOD functions                                              | Oracle supports the ABS function. Oracle's MOD function is similar to the standard, though the behavior is different if the two arguments are of opposite sign.                                                                                                                                                                              |
| T471, Result sets return value                                           | PL/SQL ref cursors provide all the functionality of the standard's result set cursors.                                                                                                                                                                                                                                                       |
| T491, LATERAL derived tables                                             | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                          |
| T501, Enhanced EXISTS predicate                                          | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                          |
| T511, Transaction counts                                                 | Oracle supports the count of transactions committed and rolled back via the system views V\$STATNAME and V\$SESSTAT.                                                                                                                                                                                                                         |
| T521, Named arguments in CALL statement                                  | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                          |
| T522, Default values for IN parameters of SQL-invoked procedures         | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                          |
| T524, Named arguments in routine invocations other than a CALL statement | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                          |
| T525, Default values for parameters of SQL-invoked functions             | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                          |
| T571, Array-returning external SQL-invoked function                      | Oracle table functions returning a varray can be defined in external programming languages. When declaring such functions in SQL, use the CREATE FUNCTION command with the PIPELINED USING clause.                                                                                                                                           |
| T572, Multiset-returning external SQL-invoked function                   | Oracle table functions returning a nested table can be defined in external programming languages. When declaring such functions in SQL, use the CREATE FUNCTION command with the PIPELINED USING clause. In the body of the function, use the OCITable interface. The function must be invoked within the TABLE operator in the FROM clause. |
| T581, Regular expressions substring functions                            | Oracle provides the REGEXP_SUBSTR function to perform substring operations using regular expression matching.                                                                                                                                                                                                                                |

**Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation**

| Feature ID, Feature                                                              | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| T591, UNIQUE constraints of possibly null columns                                | Oracle permits a <code>UNIQUE</code> constraint on one or more nullable columns. If the <code>UNIQUE</code> constraint is on a single column, then the semantics are the same as the standard (the constraint permits any number of rows that are null in the designated column). If the <code>UNIQUE</code> constraint is on two or more columns, then the semantics are nonstandard. Oracle permits any number of rows that are null in all the designated columns. Unlike the standard, if a row is non-null in at least one of the designated columns, then another row having the same values in the non-null columns of the constraint is a constraint violation and not permitted. |
| T611, Elementary OLAP operations                                                 | Oracle fully supports this feature, except that <code>DISTINCT</code> is only supported in conjunction with window partitioning but not with window framing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| T612, Advanced OLAP operations                                                   | Oracle supports the following elements of this feature:<br><code>PERCENT_RANK</code> , <code>CUME_DIST</code> , <code>WIDTH_BUCKET</code> , <code>hypothetical set functions</code> , <code>PERCENTILE_CONT</code> , <code>PERCENTILE_DISC</code> , and <code>ROW_NUMBER</code> .<br>Oracle does not support the following element of this feature: <ul style="list-style-type: none"><li>• <code>ROW_NUMBER</code> without <code>ORDER BY</code></li></ul>                                                                                                                                                                                                                               |
| T613, Sampling                                                                   | Oracle uses the keyword <code>SAMPLE</code> instead of the standard's keyword, <code>TABLESAMPLE</code> . Oracle uses the keyword <code>BLOCK</code> instead of the standard's keyword, <code>SYSTEM</code> . Oracle uses the absence of the keyword <code>BLOCK</code> to indicate a Bernoulli sampling of rows, indicated in the standard by the keyword <code>BERNOULLI</code> . Oracle does not support sampling of derived tables or views that are not key-preserving. Oracle does not permit sampling in a subquery of a <code>DELETE</code> , <code>UPDATE</code> or <code>MERGE</code> statement.                                                                                |
| T614, <code>NTILE</code> function                                                | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| T829, <code>JSON_QUERY</code> : array wrapper options                   | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| T832, SQL/JSON path language: item method                               | Oracle fully supports the following item methods: <ul style="list-style-type: none"> <li><code>abs</code></li> <li><code>ceiling</code></li> <li><code>double</code></li> <li><code>floor</code></li> </ul> Oracle provides the following comparable support: <ul style="list-style-type: none"> <li><code>date</code> and <code>timestamp</code> are comparable to the standard's <code>datetime</code></li> </ul> Oracle extends this feature by supporting the following item methods: <ul style="list-style-type: none"> <li><code>length</code></li> <li><code>lower</code></li> <li><code>number</code></li> <li><code>string</code></li> <li><code>upper</code></li> </ul> |
| T833, SQL/JSON path language: multiple subscripts                       | Oracle fully supports this feature, except that subscripts have to be specified in strictly monotonically increasing order.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| T834, SQL/JSON path language: wildcard member accessor                  | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| T835, SQL/JSON path language: filter expression                         | Oracle supports the filter expression as the last step of the SQL/JSON path expression in <code>JSON_EXISTS</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Table C-2 (Cont.) Oracle Support for Optional Features of SQL/Foundation**

| Feature ID, Feature                                         | Support                                                                                                            |
|-------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| T839, Formatted cast of datetimes to/from character strings | Oracle supports this feature with a minor syntactic difference: Oracle uses a comma instead of the keyword FORMAT. |

## Oracle Compliance with SQL/CLI

The Oracle ODBC driver conforms to SQL/CLI.

## Oracle Compliance with SQL/PSM

Oracle PL/SQL provides functionality equivalent to SQL/PSM, with minor syntactic differences, such as the spelling or arrangement of keywords.

## Oracle Compliance with SQL/MED

Oracle does not comply with SQL/MED.

## Oracle Compliance with SQL/OLB

Oracle SQLJ conforms to SQL/OLB:1999 and not yet to SQL/OLB:2016.

## Oracle Compliance with SQL/JRT

Oracle fully supports stored routines and SQL types implemented in Java(TM). Oracle provides equivalent support for the creation and maintenance of such types and procedures. Oracle's capabilities are in general a superset of the functionality defined by the standard.

## Oracle Compliance with SQL/XML

The XML data type in the standard is `XML`. The Oracle equivalent data type is `XMLType`. A feature of the standard is considered to be fully supported if the only difference between Oracle and the standard is the spelling of the data type name.

[Table C-3](#) describes Oracle's support for the features of SQL/XML.

**Table C-3 Oracle Support for Features of SQL/XML**

| Feature ID, Feature         | Support                                                                                             |
|-----------------------------|-----------------------------------------------------------------------------------------------------|
| X010, XML type              | Oracle fully supports this feature.                                                                 |
| X011, Arrays of XML types   | Oracle supports this feature using named array types                                                |
| X012, Multisets of XML type | The Oracle equivalent of a multiset of XML type is a nested table with a single column of XML type. |

**Table C-3 (Cont.) Oracle Support for Features of SQL/XML**

| Feature ID, Feature                    | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| X038, XMLText                          | The Oracle XMLCData function may be used to create a text node.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| X040, Basic table mapping              | Oracle table mappings are available through a Java interface and through a package. Oracle table mappings have been generalized to map queries and not just tables. To map only a table: SELECT * FROM <i>table_name</i> . This provides support for the following elements of this feature: <ul style="list-style-type: none"> <li>X041, Basic table mapping: null absent</li> <li>X042, Basic table mapping: null as nil</li> <li>X043, Basic table mapping: table as forest</li> <li>X044, Basic table mapping: table as element</li> <li>X045, Basic table mapping: with target namespace</li> <li>X046, Basic table mapping: data mapping</li> <li>X047, Basic table mapping: metadata mapping</li> <li>X049, Basic table mapping: hex encoding</li> </ul> Oracle does not support the following element of this feature: <ul style="list-style-type: none"> <li>X048, Basic table mapping: base64 encoding</li> </ul> |
| X041, Basic table mapping: null absent | See X040.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| X042, Basic table mapping: null as nil | See X040.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| X047, Basic table mapping: metadata mapping                            | See X040.                                                                                                                                                                                                                                                                                                                   |
| X049, Basic table mapping: hex encoding                                | See X040.                                                                                                                                                                                                                                                                                                                   |
| X060, XMLParse: Character string input and CONTENT option              | Oracle does not support the {PRESERVE   STRIP} WHITESPACE syntax. The behavior is always STRIP WHITESPACE.                                                                                                                                                                                                                  |
| X061, XMLParse: Character string input and DOCUMENT option             | Oracle does not support the {PRESERVE   STRIP} WHITESPACE syntax. The behavior is always STRIP WHITESPACE.                                                                                                                                                                                                                  |
| X069, XMLSERIALIZE: INDENT                                             | Oracle extends this feature with the ability to specify an indent size.                                                                                                                                                                                                                                                     |
| X070, XMLSerialize: Character string serialization and CONTENT option  | Oracle supports this feature, with this restriction: <ul style="list-style-type: none"><li>• In the standard, the choice of DOCUMENT or CONTENT is optional; in Oracle, you must specify one of these.</li></ul> Oracle extends this feature as follows: the standard requires a target data type; Oracle defaults to CLOB. |
| X071, XMLSerialize: Character string serialization and DOCUMENT option | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                         |
| X072, XMLSerialize: Character string serialization                     | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                         |
| X073, XMLSerialize: BLOB serialization and CONTENT option              | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                         |
| X074, XMLSerialize: BLOB serialization and DOCUMENT option             | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                         |
| X075, XMLSerialize: BLOB serialization                                 | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                         |
| X076, XMLSerialize: VERSION option                                     | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                         |
| X077, XMLSerialize: explicit ENCODING option                           | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                         |

**Table C-3 (Cont.) Oracle Support for Features of SQL/XML**

| Feature ID, Feature                                                                                     | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X080, Namespaces in XML publishing                                                                      | In the Oracle implementation of <code>XMLElement</code> , <code>XMLAttributes</code> are used to define namespaces ( <code>XMLNamespaces</code> is not implemented). However, <code>XMLAttributes</code> is not supported for <code>XMLForest</code> .                                                                                                                                                                                                                                                           |
| X086, XML namespace declarations in <code>XMLTable</code>                                               | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| X090, XML document predicate                                                                            | In Oracle, you can test whether an XML value is a document by using the <code>ISFRAGMENT</code> method.                                                                                                                                                                                                                                                                                                                                                                                                          |
| X096, <code>XMLExists</code>                                                                            | Oracle fully supports this feature, with this exception: Oracle only supports passing by value, so the keywords <code>BY VALUE</code> are optional at the beginning of the <code>PASSING</code> clause, and not supported on individual arguments.                                                                                                                                                                                                                                                               |
| X120, XML parameters in SQL routines                                                                    | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| X121, XML parameters in external routines                                                               | Oracle supports XML values passed to external routines using a non-standard interface.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| X141, <code>IS VALID</code> predicate: data drive case                                                  | The <code>XMLISVALID</code> method is equivalent to the <code>IS VALID</code> predicate, and supports the data-driven case.                                                                                                                                                                                                                                                                                                                                                                                      |
| X142, <code>IS VALID</code> predicate: <code>ACCORDING TO</code> clause                                 | The <code>XMLISVALID</code> method is equivalent to the <code>IS VALID</code> predicate, and includes the equivalent of the <code>ACCORDING TO</code> clause.                                                                                                                                                                                                                                                                                                                                                    |
| X143, <code>IS VALID</code> predicate: <code>ELEMENT</code> clause                                      | The <code>XMLISVALID</code> method is equivalent to the <code>IS VALID</code> predicate, and includes the equivalent of the <code>ELEMENT</code> clause.                                                                                                                                                                                                                                                                                                                                                         |
| X144, <code>IS VALID</code> predicate: schema location                                                  | The <code>XMLISVALID</code> method is equivalent to the <code>IS VALID</code> predicate, and supports the specification of a schema location for a registered XML Schema.                                                                                                                                                                                                                                                                                                                                        |
| X145, <code>IS VALID</code> predicate outside check constraints                                         | The <code>XMLISVALID</code> method is equivalent to the <code>IS VALID</code> predicate, and may be used outside check constraints.                                                                                                                                                                                                                                                                                                                                                                              |
| X151, <code>IS VALID</code> predicate with <code>DOCUMENT</code> option                                 | The <code>XMLISVALID</code> method is equivalent to the <code>IS VALID</code> predicate, and performs validation equivalent to the <code>DOCUMENT</code> clause. ( <code>XMLISVALID</code> does not support "content" validation.)                                                                                                                                                                                                                                                                               |
| X156, <code>IS VALID</code> predicate: optional <code>NAMESPACE</code> with <code>ELEMENT</code> clause | The <code>XMLISVALID</code> method is equivalent to the <code>IS VALID</code> predicate, and may be used to validate against an element in any namespace.                                                                                                                                                                                                                                                                                                                                                        |
| X157, <code>IS VALID</code> predicate: <code>NO NAMESPACE</code> with <code>ELEMENT</code> clause       | The <code>XMLISVALID</code> method is equivalent to the <code>IS VALID</code> predicate, and may be used to validate against an element in the "no name" namespace.                                                                                                                                                                                                                                                                                                                                              |
| X160, Basic Information Schema for registered XML Schemas                                               | The Oracle static data dictionary view <code>ALL_XML_SCHEMAS</code> provides a list of the registered XML schemas that are accessible to the current user. The <code>ALL_XML_SCHEMAS.SCHEMA_URL</code> column corresponds to the standard <code>XML_SCHEMAS.XML_SCHEMA_LOCATION</code> column. The target namespace of the registered XML Schemas can be learned by examining <code>ALL_XML_SCHEMAS.SCHEMA</code> . Oracle has no equivalents for the other columns of the standard's <code>XML_SCHEMAS</code> . |

**Table C-3 (Cont.) Oracle Support for Features of SQL/XML**

| Feature ID, Feature                                                     | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X161, Advanced Information Schema for registered XML Schemas            | Oracle does not have static data dictionary views corresponding to <code>XML_SCHEMA_NAMESPACES</code> and <code>XML_SCHEMA_ELEMENTS</code> in the standard. However, all the information about registered XML Schemas may be learned by examining the actual XML Schema, which is found in the <code>ALL_XML_SCHEMAS.SCHEMA</code> column. This may also be examined to learn whether a registered XML Schema is nondeterministic, and which of its namespaces and elements are nondeterministic. |
| X191, <code>XML(DOCUMENT(XMLSHEMA))</code> type                         | Oracle does not support this syntax. However, a column of a table can be constrained by a registered XML Schema, in which case all values of the column will be of <code>XML(DOCUMENT(XMLSHEMA))</code> type.                                                                                                                                                                                                                                                                                     |
| X200, XMLQuery                                                          | <p>Oracle fully supports the following elements of this feature:</p> <ul style="list-style-type: none"> <li>• X201, XMLQuery: RETURNING CONTENT</li> <li>• X203, XMLQuery: passing a context item</li> <li>• X204, XMLQuery: initializing an XQuery variable</li> <li>• X206, XMLQuery: NULL ON EMPTY option</li> </ul> <p>Oracle only supports passing by value, so the keywords BY VALUE are optional at the beginning of the PASSING clause, and not supported on individual arguments.</p>    |
| X201, XMLQuery: RETURNING CONTENT                                       | See X200.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| X204, XMLQuery: initializing an XQuery variable                         | See X200.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| X206, XMLQuery: NULL ON EMPTY option                                    | See X200.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| X221, XML passing mechanism BY VALUE                                    | Oracle supports the BY VALUE clause in XMLQuery, XMLTable and XMLExists. In these, BY VALUE is supported as optional syntax at the beginning of an argument list, but not as a modifier on an individual argument or column.                                                                                                                                                                                                                                                                      |
| X232, <code>XML(CONTENT(ANY))</code> type                               | Oracle does not support this syntax as a type modifier, but the Oracle XMLType supports this data type for transient values. Persistent values are of type <code>XML(DOCUMENT(ANY))</code> , which is a subset of <code>XML(CONTENT(ANY))</code> .                                                                                                                                                                                                                                                |
| X241, RETURNING CONTENT in XML publishing                               | Oracle does not support this syntax. In Oracle, the behavior of the publishing functions ( <code>XMLAgg</code> , <code>XMLComment</code> , <code>XMLConcat</code> , <code>XMLElement</code> , <code>XMLForest</code> , and <code>XMLPi</code> ) is always RETURNING CONTENT.                                                                                                                                                                                                                      |
| X251, Persistent XML values of <code>XML(DOCUMENT(UNTYPED))</code> type | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| X252, Persistent values of type <code>XML(DOCUMENT(ANY))</code>         | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table C-3 (Cont.) Oracle Support for Features of SQL/XML**

| Feature ID, Feature                                      | Support                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| X256, Persistent values of XML(DOCUMENT(XMLSCHEMA)) type | Oracle fully supports this feature.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| X260, XML type, ELEMENT clause                           | Oracle does not support this syntax. However, a column of a table may be constrained by a top-level element in a registered XML Schema.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| X263, XML type: NO NAMESPACE with ELEMENT clause         | Oracle does not support this syntax. However, a column of a table may be constrained by a top-level element in the "no name" namespace of a registered XML Schema.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| X264, XML type: schema location                          | Oracle does not support this syntax. However, a column of a table may be constrained by a registered XML Schema that is identified by a schema location.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| X271, XMLValidate: data driven case                      | The SCHEMVALIDATE method is equivalent to XMLValidate, and supports the data-driven case.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| X272, XMLValidate: ACCORDING TO clause                   | The SCHEMVALIDATE method is equivalent to XMLValidate, and may be used to specify a particular registered XML Schema.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| X273, XMLValidate: ELEMENT clause                        | The SCHEMVALIDATE method is equivalent to XMLValidate, and may be used to specify a particular element of a particular registered XML Schema.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| X274, XMLValidate: schema location                       | The SCHEMVALIDATE method is equivalent to XMLValidate, and may be used to specify a particular registered XML Schema by its schema location URL.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| X281, XMLValidate with DOCUMENT option                   | The SCHEMVALIDATE method is equivalent to XMLValidate. SCHEMVALIDATE performs validation only of XML documents (not content).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| X286, XMLValidate: NO NAMESPACE with ELEMENT clause      | The SCHEMVALIDATE method is equivalent to XMLValidate, and may be used to specify a particular element in the "no name" namespace of a particular registered XML Schema.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| X300, XMLTable                                           | Oracle does not support reverse axes in the column path expressions. Aside from that restriction, Oracle fully supports the following elements of this feature: <ul style="list-style-type: none"> <li>• X086, XML namespace declarations in XMLTable</li> <li>• X302, XMLTable with ordinality column</li> <li>• X303, XMLTable: column default option</li> <li>• X304, XMLTable: passing a context item</li> <li>• X305, XMLTable: initializing an XQuery variable</li> </ul> <p>Oracle only supports passing by value, so the keywords BY VALUE are optional at the beginning of the PASSING clause, and not supported on individual arguments.</p> |
| X302, XMLTable with ordinality column                    | See X300.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| X303, XMLTable: column default option                    | See X300.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| X304, XMLTable: passing a context item                   | See X300.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Table C-3 (Cont.) Oracle Support for Features of SQL/XML**

| Feature ID, Feature                             | Support   |
|-------------------------------------------------|-----------|
| X305, XMLTable: initializing an XQuery variable | See X300. |

## Oracle Compliance with FIPS 127-2

Oracle complied fully with last Federal Information Processing Standard (FIPS), which was FIPS PUB 127-2. That standard is no longer published. However, for users whose applications depend on information about the sizes of some database constructs that were defined in FIPS 127-2, the details of our compliance are listed in [Table C-4](#).

**Table C-4 Sizing for Database Constructs**

| Database Constructs                            | FIPS  | Oracle Database |
|------------------------------------------------|-------|-----------------|
| Length of an identifier (in bytes)             | 18    | 128             |
| Length of CHARACTER data type (in bytes)       | 240   | 2,000           |
| Decimal precision of NUMERIC data type         | 15    | 38              |
| Decimal precision of DECIMAL data type         | 15    | 38              |
| Decimal precision of INTEGER data type         | 9     | 38              |
| Decimal precision of SMALLINT data type        | 4     | 38              |
| Binary precision of FLOAT data type            | 20    | 126             |
| Binary precision of REAL data type             | 20    | 63              |
| Binary precision of DOUBLE PRECISION data type | 30    | 126             |
| Columns in a table                             | 100   | 1,000           |
| Values in an INSERT statement                  | 100   | 1,000           |
| SET clauses in an UPDATE statement (Note 1)    | 20    | 1,000           |
| Length of a row (Note2, Note 3)                | 2,000 | 2,000,000       |
| Columns in a UNIQUE constraint                 | 6     | 32              |
| Length of a UNIQUE constraint (Note 2)         | 120   | (Note 4)        |
| Length of foreign key column list (Note 2)     | 120   | (Note 4)        |
| Columns in a GROUP BY clause                   | 6     | 255 (Note 5)    |
| Length of GROUP BY column list                 | 120   | (Note 5)        |
| Sort specifications in ORDER BY clause         | 6     | 255 (Note 5)    |
| Length of ORDER BY column list                 | 120   | (Note 5)        |
| Columns in a referential integrity constraint  | 6     | 32              |
| Tables referenced in a SQL statement           | 15    | No limit        |
| Cursors simultaneously open                    | 10    | (Note 6)        |
| Items in a SELECT list                         | 100   | 1,000           |

**Note 1:** The number of `SET` clauses in an `UPDATE` statement refers to the number items separated by commas following the `SET` keyword.

**Note 2:** The FIPS PUB defines the length of a collection of columns to be the sum of: twice the number of columns, the length of each character column in bytes, decimal precision plus 1 of each exact numeric column, binary precision divided by 4 plus 1 of each approximate numeric column.

**Note 3:** The Oracle limit for the maximum row length is based on the maximum length of a row containing a `LONG` value of length 2 gigabytes and 999 `VARCHAR2` values, each of length 4000 bytes:  $2(254) + 231 + (999(4000))$ .

**Note 4:** The Oracle limit for a `UNIQUE` key is half the size of an Oracle data block (specified by the initialization parameter `DB_BLOCK_SIZE`) minus some overhead.

**Note 5:** Oracle places no limit on the number of columns in a `GROUP BY` clause or the number of sort specifications in an `ORDER BY` clause. However, the sum of the sizes of all the expressions in either a `GROUP BY` clause or an `ORDER BY` clause is limited to the size of an Oracle data block (specified by the initialization parameter `DB_BLOCK_SIZE`) minus some overhead.

**Note 6:** The Oracle limit for the number of cursors simultaneously opened is specified by the initialization parameter `OPEN_CURSORS`. The maximum value of this parameter depends on the memory available on your operating system and exceeds 100 in all cases.

## Oracle Extensions to Standard SQL

Oracle supports numerous features that extend beyond standard SQL. If you are concerned with the portability of your applications to other implementations of SQL, then use Oracle's FIPS Flagger to help identify the use of Oracle extensions to Entry SQL-92 in your embedded SQL programs. The FIPS Flagger is part of the Oracle precompilers and the SQL\*Module compiler. The FIPS Flagger can also be enabled in SQL\*Plus by using `ALTER SESSION SET FLAGGER = ENTRY`. While SQL-92 has been superseded by SQL:2016, there has been no conformance testing authority for any version of SQL since SQL-92; hence, Entry SQL-92 offers you the most assurance of portability.

 **See Also:**

*Pro\*COBOL Programmer's Guide* and *Pro\*C/C++ Programmer's Guide* for information on how to use the FIPS Flagger

## Oracle Compliance with Older Standards

This release of Oracle Database conforms to SQL:2016, the most recent edition of the SQL standard when this guide was published, as itemized in preceding sections of this appendix. Oracle does not formally claim that this release of the database conforms to SQL-92—and in particular, to SQL-92 Entry Level—or to SQL:1999, because those standards have been superseded by SQL:2016. Some, mostly minor, changes between editions of the SQL standard might affect applications. The SQL standard, or a reference discussing that standard, can be consulted to determine the details of any incompatibilities that have been introduced. One important source is Annex E of SQL/Foundation:1999, SQL/Foundation:2003, SQL/Foundation:2008, SQL/Foundation:2011, and SQL/Foundation:2016.

In some cases, this release of Oracle Database might continue to recognize constructs from older editions of SQL. Such recognition is often allowed as a valid vendor extension. It is the general policy of Oracle to keep incompatibilities between versions of the database as few as possible. This policy extends to retention of older forms when that is feasible. In any case, the differences between older SQL and SQL:2016 (as noted above) are relatively inconsequential.

## Character Set Support

Oracle supports most national, international, and vendor-specific encoded character set standards. A complete list of character sets supported by Oracle appears in *Oracle Database Globalization Support Guide*.

Unicode is a universal encoded character set that lets you store information from any language using a single character set. Unicode is required by modern standards such as XML, Java, JavaScript, and LDAP. Unicode is compliant with ISO/IEC standard 10646. For information on ISO standards, visit the Web site of the International Organization for Standardization:

<http://www.iso.ch>

Oracle Database 23c complies with version 15.0 of the Unicode Standard. For up-to-date information on the Unicode Standard, visit the Web site of the Unicode Consortium:

<http://www.unicode.org>

Oracle supports the UTF-8 encoding scheme of the Unicode Standard through the AL32UTF8 character set, the UTF-16BE encoding scheme through the AL16UTF16 character set, and the UTF-16LE encoding scheme through the AL16UTF16LE character set. AL32UTF8 is valid as the client and database character set on ASCII-based platforms. AL16UTF16 is valid as the national (`NCHAR`) character set on all platforms. AL16UTF16LE is not valid as the client, database, or national character set.

Oracle implements two deprecated Unicode compatibility encoding forms: CESU-8 through the UTF8 character set and UTF-EBCDIC through the UTFE character set. The UTF8 and UTFE character sets are not guaranteed to include updates to the Unicode standard beyond version 3.0. UTF8 is valid as the client and database character set on ASCII-based platforms and as the national (`NCHAR`) character set on all platforms. UTFE is valid as the database character set on EBCDIC-based platforms.

All mentioned Oracle character sets are supported in conversion functions.

Oracle recommends that databases on ASCII-based platforms are created with the AL32UTF8 character set and the AL16UTF16 national (`NCHAR`) character set. Oracle recommends that you avoid the use of the `NCHAR` data types and the associated national character set as they are not supported by some RDBMS components, such as Oracle Text and Oracle XDB.

## Oracle Regular Expression Support

Oracle's implementation of regular expressions conforms with the IEEE Portable Operating System Interface (POSIX) regular expression standard and to the Unicode Regular Expression Guidelines of the Unicode Consortium.

This appendix contains the following sections:

- [Multilingual Regular Expression Syntax](#)
- [Regular Expression Operator Multilingual Enhancements](#)
- [Perl-influenced Extensions in Oracle Regular Expressions](#)

### Multilingual Regular Expression Syntax

[Table D-1](#) lists the full set of operators defined in the POSIX standard Extended Regular Expression (ERE) syntax. Oracle follows the exact syntax and matching semantics for these operators as defined in the POSIX standard for matching ASCII (English language) data. For more complete descriptions of the operators, examples of their use, and Oracle multilingual enhancements of the operators, refer to *Oracle Database Development Guide*. Notes following the table provide more complete descriptions of the operators and their functions, as well as Oracle multilingual enhancements of the operators. [Table D-2](#) summarizes Oracle support for and multilingual enhancement of the POSIX operators.

**Table D-1 Regular Expression Operators and Metasymbols**

| Operator | Description                                                                                                                                                                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| \        | The backslash character can have four different meanings depending on the context. It can: <ul style="list-style-type: none"><li>• Stand for itself</li><li>• Quote the next character</li><li>• Introduce an operator</li><li>• Do nothing</li></ul> |
| *        | Matches zero or more occurrences                                                                                                                                                                                                                      |
| +        | Matches one or more occurrences                                                                                                                                                                                                                       |
| ?        | Matches zero or one occurrence                                                                                                                                                                                                                        |
|          | Alternation operator for specifying alternative matches                                                                                                                                                                                               |
| ^        | Matches the beginning of a string by default. In multiline mode, it matches the beginning of any line anywhere within the source string.                                                                                                              |
| \$       | Matches the end of a string by default. In multiline mode, it matches the end of any line anywhere within the source string.                                                                                                                          |
| .        | Matches any character in the supported character set except NULL                                                                                                                                                                                      |

**Table D-1 (Cont.) Regular Expression Operators and Metasymbols**

| Operator | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [ ]      | Bracket expression for specifying a matching list that should match any one of the expressions represented in the list. A non-matching list expression begins with a circumflex (^) and specifies a list that matches any character except for the expressions represented in the list.<br><br>To specify a right bracket (]) in the bracket expression, place it first in the list (after the initial circumflex (^), if any).<br><br>To specify a hyphen in the bracket expression, place it first in the list (after the initial circumflex (^), if any), last in the list, or as an ending range point in a range expression. |
| ( )      | Grouping expression, treated as a single subexpression                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| {m}      | Matches exactly m times                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| {m,}     | Matches at least m times                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| {m,n}    | Matches at least m times but no more than n times                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| \n       | The backreference expression (n is a digit between 1 and 9) matches the n <sup>th</sup> subexpression enclosed between '(' and ')' preceding the \n                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| [..]     | Specifies one collation element, and can be a multicharacter element (for example, [.ch.] in Spanish)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| [: :]    | Specifies character classes (for example, [:alpha:]). It matches any character within the character class.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| [==]     | Specifies equivalence classes. For example, [=a=] matches all characters having base letter 'a'.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Regular Expression Operator Multilingual Enhancements

When applied to multilingual data, Oracle's implementation of the POSIX operators extends beyond the matching capabilities specified in the POSIX standard. [Table D-2](#) shows the relationship of the operators in the context of the POSIX standard.

- The first column lists the supported operators.
- The second and third columns indicate whether the POSIX standard (Basic Regular Expression—BRE and Extended Regular Expression—ERE, respectively) defines the operator
- The fourth column indicates whether Oracle's implementation extends the operator's semantics for handling multilingual data.

Oracle lets you enter multibyte characters directly, if you have a direct input method, or you can use functions to compose the multibyte characters. You cannot use the Unicode hexadecimal encoding value of the form '\xxxx'. Oracle evaluates the characters based on the byte values used to encode the character, not the graphical representation of the character. All accented characters are considered word characters.

**Table D-2** POSIX and Multilingual Operator Relationships

| Operator | POSIX BRE syntax | POSIX ERE Syntax | Multilingual Enhancement |
|----------|------------------|------------------|--------------------------|
| \        | Yes              | Yes              | —                        |
| *        | Yes              | Yes              | —                        |

## Perl-influenced Extensions in Oracle Regular Expressions

Oracle Database regular expression functions and conditions accept a number of Perl-influenced operators that are in common use, although not part of the POSIX standard. [Table D-3](#) lists those operators. For more complete descriptions with examples, refer to *Oracle Database Development Guide*.

**Table D-3** Perl-influenced Operators in Oracle Regular Expressions

| Operator | Description                                                                                      |
|----------|--------------------------------------------------------------------------------------------------|
| \d       | A digit character.                                                                               |
| \D       | A nondigit character.                                                                            |
| \w       | A word character.                                                                                |
| \W       | A nonword character.                                                                             |
| \s       | A whitespace character.                                                                          |
| \S       | A non-whitespace character.                                                                      |
| \A       | Matches only at the beginning of a string, or before a newline character at the end of a string. |
| \Z       | Matches only at the end of a string.                                                             |
| *?       | Matches the preceding pattern element 0 or more times (nongreedy).                               |

**Table D-3 (Cont.) Perl-influenced Operators in Oracle Regular Expressions**

| Operator | Description                                                                                           |
|----------|-------------------------------------------------------------------------------------------------------|
| +?       | Matches the preceding pattern element 1 or more times (nongreedy).                                    |
| ??       | Matches the preceding pattern element 0 or 1 time (nongreedy).                                        |
| {n}?     | Matches the preceding pattern element exactly <i>n</i> times (nongreedy).                             |
| {n,m}?   | Matches the preceding pattern element at least <i>n</i> but not more than <i>m</i> times (nongreedy). |

## Oracle SQL Reserved Words and Keywords

This appendix contains the following sections:

- [Oracle SQL Reserved Words](#)
- [Oracle SQL Keywords](#)

### Oracle SQL Reserved Words

This section lists Oracle SQL reserved words. You cannot use Oracle SQL reserved words as nonquoted identifiers. Quoted identifiers can be reserved words, although this is not recommended.

 **Note:**

In addition to the following reserved words, Oracle uses system-generated names beginning with "SYS\_" for implicitly generated schema objects and subobjects. Oracle discourages you from using this prefix in the names you explicitly provide to your schema objects and subobjects to avoid possible conflict in name resolution.

The `V$RESERVED_WORDS` data dictionary view provides additional information on each reserved word, including whether it is always reserved or is reserved only for particular uses. Refer to *Oracle Database Reference* for more information.

Words followed by an asterisk (\*) are also ANSI reserved words.

**Note 1:** This keyword is only reserved for use as an attribute name.

**Note 2:** You cannot use the uppercase word ROWID, either quoted or nonquoted, as a column name. However, you can use the uppercase word as a quoted identifier that is not a column

name, and you can use the word with one or more lowercase letters (for example, "Rowid" or "rowid") as any quoted identifier, including a column name.

## Oracle SQL Keywords

Oracle SQL keywords are not reserved. However, Oracle uses them internally in specific ways. Therefore, if you use these words as names for objects and object parts, then your SQL statements may be more difficult to read and may lead to unpredictable results.

You can obtain a list of keywords by querying the `V$RESERVED_WORDS` data dictionary view. All keywords in the view that are not listed as always reserved or reserved for a specific use are Oracle SQL keywords. Refer to *Oracle Database Reference* for more information.

# Extended Examples

The body of the *SQL Language Reference* contains examples for almost every reference topic. This appendix contains lengthy examples that are not appropriate in the context of a single SQL statement. These examples are intended to provide uninterrupted the series of steps that you would use to take advantage of particular Oracle functionality. They do not replace the syntax diagrams and semantics found for each individual SQL statement in the body of the reference. Use the cross-references provided to access additional information, such as privileges required and restrictions, as well as syntax.

This appendix contains the following sections:

- [Using Extensible Indexing](#)
- [Using XML in SQL Statements](#)

## Using Extensible Indexing

This section provides examples of the steps entailed in a simple but realistic extensible indexing scenario.

Suppose you want to rank the salaries in the `HR.employees` table and then find those that rank between 10 and 20. You could use the `DENSE_RANK` function, as follows:

```
SELECT last_name, salary FROM
  (SELECT last_name, DENSE_RANK() OVER
    (ORDER BY salary DESC) rank_val, salary FROM employees)
 WHERE rank_val BETWEEN 10 AND 20;
```

 **See Also:**

[DENSE\\_RANK](#)

This nested query is somewhat complex, and it requires a full scan of the `employees` table as well as a sort. An alternative would be to use extensible indexing to achieve the same goal. The resulting query will be simpler. The query will require only an index scan and a table access by rowid, and will therefore perform much more efficiently.

The first step is to create the implementation type `position_im`, including method headers for index definition, maintenance, and creation. Most of the type body uses PL/SQL, which is shown in italics.

The type must created with the `AUTHID CURRENT_USER` clause because of the `EXECUTE IMMEDIATE` statement inside the function `ODCIINDEXCREATE()`. By default that function runs with the definer rights. When the function is called in the subsequent creation of the domain index, the invoker does not have the same rights.

 **See Also:**

- [CREATE TYPE](#) and [CREATE TYPE BODY](#)
- *Oracle Database Data Cartridge Developer's Guide* for complete information on the ODCI routines in this statement

```

The next step is to create the functional implementation function\_for\_position\_between for the operator that will be associated with the indextype. (The PL/SQL blocks are shown in parentheses.)

This function is for use with an index-based function evaluation. Therefore, it takes an index context and scan context as parameters.

### See Also:

- *Oracle Database Data Cartridge Developer's Guide* for information on creating index-based functional implementation
- [CREATE FUNCTION](#) and *Oracle Database PL/SQL Language Reference*

```

CREATE OR REPLACE FUNCTION function_for_position_between
  (col NUMBER, lower_pos NUMBER, upper_pos NUMBER,

                            'col_val FROM ' || storage_tab_name ||
                            ' WHERE col_val < ' || upper_bound || ' ORDER BY ' ||
                            'col_val DESC) WHERE rownum <= ' ||
                            (upper_pos - lower_pos);
        EXECUTE IMMEDIATE lower_bound_stmt INTO lower_bound;
      ELSE
        lower_bound := upper_bound;
      END IF;
      IF (lower_bound IS NULL) THEN
        lower_bound := upper_bound;
      END IF;
      /* Store the lower and upper bounds for future function invocations for
         the positions.
     */
      scanctx := position_im(0, 0, lower_bound, upper_bound);
    END IF;
    /* Fetch the column value corresponding to the rowid, and see if it falls
       within the determined range.
     */
    col_val_stmt := 'Select col_val FROM ' || storage_tab_name ||
                  ' WHERE base_rowid = ''' || indexctx.Rid || '''';
    EXECUTE IMMEDIATE col_val_stmt INTO column_value;
    IF (column_value <= scanctx.upper_bound AND
        column_value >= scanctx.lower_bound AND
        scanflg = ODCICONST.RegularCall) THEN
      RETURN 1;
    END IF;
  END IF;
END;
  
```

```
ELSE
    RETURN 0;
END IF;
ELSE
    RAISE_APPLICATION_ERROR(-20101, 'A column that has a domain index of' ||
                           'Position indextype must be the first argument');
END IF;
END;
/
```

Next, create the `position_between` operator, which uses the `function_for_position_between` function. The operator takes an indexed NUMBER column as the first argument, followed by a NUMBER lower and upper bound as the second and third arguments.

 **See Also:**

[CREATE OPERATOR](#)

```
CREATE OR REPLACE OPERATOR position_between
    BINDING (NUMBER, NUMBER, NUMBER) RETURN NUMBER
    WITH INDEX CONTEXT, SCAN CONTEXT position_im
    USING function_for_position_between;
```

In this CREATE OPERATOR statement, the WITH INDEX CONTEXT, SCAN CONTEXT `position_im` clause is included so that the index context and scan context are passed in to the functional evaluation, which is index based.

Now create the `position_indextype` indextype for the `position_operator`:

 **See Also:**

[CREATE INDEXTYPE](#)

```
CREATE INDEXTYPE position_indextype
    FOR position_between(NUMBER, NUMBER, NUMBER)
    USING position_im;
```

The operator `position_between` uses an index-based functional implementation. Therefore, a domain index must be defined on the referenced column so that the index information can be passed into the functional evaluation. So the final step is to create the domain index `salary_index` using the `position_indextype` indextype:

 **See Also:**

[CREATE INDEX](#)

```
CREATE INDEX salary_index ON employees(salary)
    INDEXTYPE IS position_indextype;
```

Now you can use the `position_between` operator function to rewrite the original query as follows:

```
SELECT last_name, salary FROM employees
    WHERE position_between(salary, 10, 20)=1
    ORDER BY salary DESC, last_name;
```

| LAST_NAME  | SALARY |
|------------|--------|
| Tucker     | 10000  |
| King       | 10000  |
| Baer       | 10000  |
| Bloom      | 10000  |
| Fox        | 9600   |

| Olsen      | 8000   |
| Smith      | 8000   |
| Kaufling   | 7900   |

## Using XML in SQL Statements

This section describes some of the ways you can use `XMLType` data in the database.

### XMLType Tables

The sample schema `oe` contains a table `warehouses`, which contains an `XMLType` column `warehouse_spec`. Suppose you want to create a separate table with the `warehouse_spec` information. The following example creates a very simple `XMLType` table with one `CLOB` column:

```
CREATE TABLE xwarehouses OF XMLTYPE
    XMLTYPE STORE AS CLOB;
```

You can insert into such a table using `XMLType` syntax, as shown in the next statement. (The data inserted in this example corresponds to the data in the `warehouse_spec` column of the sample table `oe.warehouses` where `warehouse_id = 1`.)

```
INSERT INTO xwarehouses VALUES
    (xmltype('<?xml version="1.0"?>
<Warehouse>
    <WarehouseId>1</WarehouseId>
    <WarehouseName>Southlake, Texas</WarehouseName>'))
```

```

<Building>Owned</Building>
<Area>25000</Area>
<Docks>2</Docks>
<DockType>Rear load</DockType>
<WaterAccess>true</WaterAccess>
<RailAccess>N</RailAccess>
<Parking>Street</Parking>
<VClearance>10</VClearance>
</Warehouse>'));
```

 **See Also:**

*Oracle XML DB Developer's Guide* for information on `XMLType` and its member methods

You can query this table with the following statement:

```
SELECT e.getClobVal() FROM xwarehouses e;
```

CLOB columns are subject to all of the restrictions on LOB columns. To avoid these restrictions, create an XMLSchema-based table. The XMLSchema maps the XML elements to their object-relational equivalents. The following example registers an XMLSchema locally. The XMLSchema (`xwarhouses.xsd`) reflects the same structure as the `xwarehouses` table. (XMLSchema declarations use PL/SQL and the `DBMS_XMLSHEMA` package, so the example is shown in italics.)

 **See Also:**

*Oracle XML DB Developer's Guide* for information on creating XMLSchemas

```

begin
  dbms_xmlschema.registerSchema(
    'http://www.example.com/xwarehouses.xsd',
    '<schema xmlns="http://www.w3.org/2001/XMLSchema"
      targetNamespace="http://www.example.com/xwarehouses.xsd"
      xmlns:who="http://www.example.com/xwarehouses.xsd"
      version="1.0">

      <simpleType name="RentalType">
        <restriction base="string">
          <enumeration value="Rented"/>
          <enumeration value="Owned"/>
        </restriction>
      </simpleType>

      <simpleType name="ParkingType">
        <restriction base="string">
          <enumeration value="Street"/>
          <enumeration value="Lot"/>
        </restriction>
      </simpleType>

      <element name = "Warehouse">
```

```

<complexType>
  <sequence>
    <element name = "WarehouseId" type = "positiveInteger"/>
    <element name = "WarehouseName" type = "string"/>
    <element name = "Building" type = "who:RentalType"/>
    <element name = "Area" type = "positiveInteger"/>
    <element name = "Docks" type = "positiveInteger"/>
    <element name = "DockType" type = "string"/>
    <element name = "WaterAccess" type = "boolean"/>
    <element name = "RailAccess" type = "boolean"/>
    <element name = "Parking" type = "who:ParkingType"/>
    <element name = "VClearance" type = "positiveInteger"/>
  </sequence>
</complexType>
</element>
</schema>',
  TRUE, TRUE, FALSE, FALSE);
end;
/

```

Now you can create an XMLSchema-based table, as shown in the following example:

```

CREATE TABLE xwarehouses OF XMLTYPE
  XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
  ELEMENT "Warehouse";

```

By default, Oracle stores this as an object-relational table. Therefore, you can insert into it as shown in the example that follows. (The data inserted in this example corresponds to the data in the `warehouse_spec` column of the sample table `oe.warehouses` where `warehouse_id = 1.`)

```

INSERT INTO xwarehouses VALUES(  xmltype.createxml('<?xml version="1.0"?>
<who:Warehouse xmlns:who="http://www.example.com/xwarehouses.xsd"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://www.example.com/xwarehouses.xsd
  http://www.example.com/xwarehouses.xsd">
  <WarehouseId>1</WarehouseId>
  <WarehouseName>Southlake, Texas</WarehouseName>
  <Building>Owned</Building>
  <Area>25000</Area>
  <Docks>2</Docks>
  <DockType>Rear load</DockType>
  <WaterAccess>true</WaterAccess>
  <RailAccess>false</RailAccess>
  <Parking>Street</Parking>
  <VClearance>10</VClearance>
  </who:Warehouse>'));
  ...

```

You can define constraints on an XMLSchema-based table. To do so, you use the `XMLDATA` pseudocolumn to refer to the appropriate attribute within the `Warehouse` XML element:

```

ALTER TABLE xwarehouses ADD (PRIMARY KEY(XMLDATA."WarehouseId"));

```

Because the data in `xwarehouses` is stored object relationally, Oracle rewrites queries to this `XMLType` table to go to the underlying storage when possible. Therefore the following queries would use the index created by the primary key constraint in the preceding example:

```

SELECT * FROM xwarehouses x
  WHERE EXISTSNODE(VALUE(x), '/Warehouse[WarehouseId="1"]',
    'xmlns:who="http://www.example.com/xwarehouses.xsd") = 1;

SELECT * FROM xwarehouses x
  WHERE EXTRACTVALUE(VALUE(x), '/Warehouse/WarehouseId',
    'xmlns:who="http://www.example.com/xwarehouses.xsd") = 1;
  
```

You can also explicitly create indexes on XMLSchema-based tables, which greatly enhance the performance of subsequent queries. You can create object-relational views on XMLType tables, and you can create XMLType views on object-relational tables.

## XMLType Columns

The sample table oe.warehouses was created with a warehouse\_spec column of type XMLType. The examples in this section create a shortened form of the oe.warehouses table, using two different types of storage.

The first example creates a table with an XMLType table stored as a CLOB. This table does not require an XMLSchema, so the content structure is not predetermined:

```

CREATE TABLE xwarehouses (
  warehouse_id      NUMBER,
  warehouse_spec    XMLTYPE)
  XMLTYPE warehouse_spec STORE AS CLOB
  (TABLESPACE example
  STORAGE (INITIAL 6144)
  CHUNK 4000
  NOCACHE LOGGING);
  
```

The following example creates a similar table, but stores the XMLType data in an object-relational XMLType column whose structure is determined by the specified XMLSchema:

```

CREATE TABLE xwarehouses (
  warehouse_id      NUMBER,
  warehouse_spec    XMLTYPE)
  XMLTYPE warehouse_spec STORE AS OBJECT RELATIONAL
  XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
  ELEMENT "Warehouse";
  
```
