- The signature of the current function matches the signature of the function when the index was created.
- The function is currently marked as `DETERMINISTIC`.

### Restrictions on Enabling Function-based Indexes

The `ENABLE` clause is subject to the following restrictions:

- You cannot specify any other clauses of `ALTER INDEX` in the same statement with `ENABLE`.
- You cannot specify this clause for an index on a temporary table. Instead, you must drop and recreate the index. You can retrieve the creation DDL for the index using the `DBMS_METADATA` package.

### DISABLE Clause

`DISABLE` applies only to a function-based index. This clause lets you disable the use of a function-based index. You might want to do so, for example, while working on the body of the

function. Afterward you can either rebuild the index or specify another `ALTER INDEX` statement with the `ENABLE` keyword.

### USABLE | UNUSABLE

Specify `UNUSABLE` to mark the index or index partition(s) or index subpartition(s) `UNUSABLE`. The space allocated for an index or index partition or subpartition is freed immediately when the object is marked `UNUSABLE`. An unusable index must be rebuilt, or dropped and re-created, before it can be used. While one partition is marked `UNUSABLE`, the other partitions of the index are still valid. You can execute statements that require the index if the statements do not access the unusable partition. You can also split or rename the unusable partition before rebuilding it. Refer to `CREATE INDEX ... USABLE | UNUSABLE` for more information.

### ONLINE

Specify `ONLINE` to indicate that DML operations on the table or partition will be allowed while marking the index `UNUSABLE`. If you specify this clause, then the database will not drop the index segments.

### Restrictions on Marking Indexes Unusable

The following restrictions apply to marking indexes unusable:

- You cannot specify `UNUSABLE` for an index on a temporary table.
- When a global index is marked `UNUSABLE` during a partition maintenance operation, the database does not drop the unusable index segments.

### VISIBLE | INVISIBLE

Use this clause to specify whether the index is visible or invisible to the optimizer. Refer to "`VISIBLE | INVISIBLE`" in `CREATE INDEX` for a full description of this clause.

### RENAME Clause

Use this clause to rename an index. The `new_index_name` is a single identifier and does not include the schema name.

### Restriction on Renaming Indexes

For a domain index, neither `index` nor any partitions of `index` should be in `IN_PROGRESS` or `FAILED` state.

#### See Also:

- *Building Domain Indexes* of the *Data Cartridge Developer's Guide*.
- *Extensible Indexing Interface* of the *Data Cartridge Developer's Guide*.
- [Renaming an Index: Example](#)

### COALESCE Clause

Specify `COALESCE` to instruct Oracle Database to merge the contents of index blocks where possible to free blocks for reuse.

## CLEANUP

Specify CLEANUP to remove orphaned index entries for records that were previously dropped or truncated by a table partition maintenance operation.

To determine whether an index contains orphaned index entries, you can query the ORPHANED\_ENTRIES column of the `USER_`, `DBA_`, `ALL_INDEXES` data dictionary views. Refer to *Oracle Database Reference* for more information.

## ONLY

Specify ONLY when you want to clean up the index without coalescing the index blocks.

### *parallel\_clause*

Use the *parallel\_clause* to specify whether to parallelize the coalesce operation.

For complete information on this clause, refer to [parallel\\_clause](#) in the documentation on CREATE TABLE.

## Restrictions on Coalescing Index Blocks

Coalescing of index blocks is subject to the following restrictions:

- You cannot specify this clause for an index on a temporary table.
- Do not specify this clause for the primary key index of an index-organized table. Instead use the COALESCE clause of ALTER TABLE.

### See Also:

- [Oracle Database Administrator's Guide](#) for more information on space management and coalescing indexes
- [COALESCE Clause](#) for information on coalescing the space of an index-organized table
- [shrink\\_clause](#) for an alternative method of compacting index segments

## MONITORING USAGE | NOMONITORING USAGE

Use this clause to determine whether Oracle Database should monitor index use.

- Specify MONITORING USAGE to begin monitoring the index. Oracle Database first clears existing information on index use, and then monitors the index for use until a subsequent ALTER INDEX ... NOMONITORING USAGE statement is executed.
- To terminate monitoring of the index, specify NOMONITORING USAGE.

To see whether the index has been used since this ALTER INDEX ... NOMONITORING USAGE statement was issued, query the USED column of the `USER_OBJECT_USAGE` data dictionary view.

 **See Also:**

*Oracle Database Reference* for information on the `USER_OBJECT_USAGE` data dictionary view

### UPDATE BLOCK REFERENCES Clause

The `UPDATE BLOCK REFERENCES` clause is valid only for normal and domain indexes on index-organized tables. Specify this clause to update all the stale guess data block addresses stored as part of the index row with the correct database address for the corresponding block identified by the primary key.

For a domain index, Oracle Database executes the `ODCIIndexAlter` routine with the `alter_option` parameter set to `AlterIndexUpdBlockRefs`. This routine enables the cartridge code to update the stale guess data block addresses in the index.

#### Restriction on UPDATE BLOCK REFERENCES

You cannot combine this clause with any other clause of `ALTER INDEX`.

#### *annotations\_clause*

For the full semantics of the annotations clause see [annotations\\_clause](#).

#### *alter\_index\_partitioning*

The partitioning clauses of the `ALTER INDEX` statement are valid only for partitioned indexes.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to *Oracle Database VLDB and Partitioning Guide* for a discussion of these restrictions.

#### Restrictions on Modifying Index Partitions

Modifying index partitions is subject to the following restrictions:

- You cannot specify any of these clauses for an index on a temporary table.
- You can combine several operations on the base index into one `ALTER INDEX` statement (except `RENAME` and `REBUILD`), but you cannot combine partition operations with other partition operations or with operations on the base index.

#### *modify\_index\_defaultAttrs*

Specify new values for the default attributes of a partitioned index.

#### Restriction on Modifying Partition Default Attributes

The only attribute you can specify for a hash-partitioned global index or for an index on a hash-partitioned table is `TABLESPACE`.

#### TABLESPACE

Specify the default tablespace for new partitions of an index or subpartitions of an index partition.

#### *logging\_clause*

Specify the default logging attribute of a partitioned index or an index partition.

Refer to [logging\\_clause](#) for a full description of this clause.

#### FOR PARTITION

Use the FOR PARTITION clause to specify the default attributes for the subpartitions of a partition of a local index on a composite-partitioned table.

#### Restriction on FOR PARTITION

You cannot specify FOR PARTITION for a list partition.

#### See Also:

"[Modifying Default Attributes: Example](#)"

#### *add\_hash\_index\_partition*

Use this clause to add a partition to a global hash-partitioned index. Oracle Database adds hash partitions and populates them with index entries rehashed from an existing hash partition of the index, as determined by the hash function. If you omit the partition name, then Oracle Database assigns a name of the form SYS\_Pn. If you omit the TABLESPACE clause, then Oracle Database places the partition in the tablespace specified for the index. If no tablespace is specified for the index, then Oracle Database places the partition in the default tablespace of the user, if one has been specified, or in the system default tablespace.

#### *modify\_index\_partition*

Use the *modify\_index\_partition* clause to modify the real physical attributes, logging attribute, or storage characteristics of index partition *partition* or its subpartitions. For a hash-partitioned global index, the only subclause of this clause you can specify is UNUSABLE.

#### COALESCE

Specify this clause to merge the contents of index partition blocks where possible to free blocks for reuse.

#### CLEANUP

Specify CLEANUP to remove orphaned index entries for records that were previously dropped or truncated by a table partition maintenance operation.

To determine whether an index partition contains orphaned index entries, you can query the ORPHANED\_ENTRIES column of the USER\_, DBA\_, ALL\_PART\_INDEXES data dictionary views. Refer to *Oracle Database Reference* for more information.

#### UPDATE BLOCK REFERENCES

The UPDATE BLOCK REFERENCES clause is valid only for normal indexes on index-organized tables. Use this clause to update all stale guess data block addresses stored in the secondary index partition.

#### Restrictions on UPDATE BLOCK REFERENCES

This clause is subject to the following restrictions:

- You cannot specify the *physical\_attributes\_clause* for an index on a hash-partitioned table.
- You cannot specify UPDATE BLOCK REFERENCES with any other clause in ALTER INDEX.

 **Note:**

If the index is a local index on a composite-partitioned table, then the changes you specify here will override any attributes specified earlier for the subpartitions of index, as well as establish default values of attributes for future subpartitions of that partition. To change the default attributes of the partition without overriding the attributes of subpartitions, use ALTER TABLE ... MODIFY DEFAULT ATTRIBUTES FOR PARTITION.

 **See Also:**

["Marking an Index Unusable: Examples"](#)

### **UNUSABLE Clause**

This clause has the same function for index partitions that it has for the index as a whole. Refer to "["USABLE | UNUSABLE"](#)".

#### ***index\_compression***

This clause is relevant for composite-partitioned indexes. Use this clause to change the compression attribute for the partition and every subpartition in that partition. Oracle Database marks each index subpartition in the partition **UNUSABLE** and you must then rebuild these subpartitions. Prefix compression must already have been specified for the index before you can specify the *prefix\_compression* clause for a partition, or advanced index compression must have already been specified for the index before you can specify the *advanced\_index\_compression* clause for a partition. You can specify this clause only at the partition level. You cannot change the compression attribute for an individual subpartition.

You can use this clause for noncomposite index partitions. However, it is more efficient to use the *rebuild\_clause* for noncomposite partitions, which lets you rebuild and set the compression attribute in one step.

#### ***rename\_index\_partition***

Use the *rename\_index\_partition* clauses to rename *index\_partition* or *subpartition* to *new\_name*.

### **Restrictions on Renaming Index Partitions**

Renaming index partitions is subject to the following restrictions:

- You cannot rename the subpartition of a list partition.

- For a partition of a domain index, *index* cannot be marked IN\_PROGRESS or FAILED, none of the partitions can be marked IN\_PROGRESS, and the partition you are renaming cannot be marked FAILED.

#### See Also:

["Renaming an Index Partition: Example"](#)

### *drop\_index\_partition*

Use the *drop\_index\_partition* clause to remove a partition and the data in it from a partitioned global index. When you drop a partition of a global index, Oracle Database marks the next index partition UNUSABLE. You cannot drop the highest partition of a global index.

#### See Also:

["Dropping an Index Partition: Example"](#)

### *split\_index\_partition*

Use the *split\_index\_partition* clause to split a partition of a global range-partitioned index into two partitions, adding a new partition to the index. This clause is not valid for hash-partitioned global indexes. Instead, use the *add\_hash\_index\_partition* clause.

Splitting a partition marked UNUSABLE results in two partitions, both marked UNUSABLE. You must rebuild the partitions before you can use them.

Splitting a partition marked USABLE results in two partitions populated with index data. Both new partitions are marked USABLE.

#### AT Clause

Specify the new noninclusive upper bound for *split\_partition\_1*. The *value\_list* must evaluate to less than the presplit partition bound for *partition\_name\_old* and greater than the partition bound for the next lowest partition (if there is one).

#### INTO Clause

Specify (optionally) the name and physical attributes of each of the two partitions resulting from the split.

#### See Also:

["Splitting a Partition: Example"](#)

### *coalesce\_index\_partition*

This clause is valid only for hash-partitioned global indexes. Oracle Database reduces by one the number of index partitions. Oracle Database selects the partition to coalesce based on

the requirements of the hash function. Use this clause if you want to distribute index entries of a selected partition into one of the remaining partitions and then remove the selected partition.

#### ***modify\_index\_subpartition***

Use the *modify\_index\_subpartition* clause to mark `UNUSABLE` or allocate or deallocate storage for a subpartition of a local index on a composite-partitioned table. All other attributes of such a subpartition are inherited from partition-level default attributes.

#### **Examples**

##### **Storing Index Blocks in Reverse Order: Example**

The following statement rebuilds index `ord_customer_ix` (created in "[Creating an Index: Example](#)") so that the bytes of the index block are stored in reverse order:

```
ALTER INDEX ord_customer_ix REBUILD REVERSE;
```

##### **Rebuilding an Index in Parallel: Example**

The following statement causes the index to be rebuilt from the existing index by using parallel execution processes to scan the old and to build the new index:

```
ALTER INDEX ord_customer_ix REBUILD PARALLEL;
```

##### **Modifying Real Index Attributes: Example**

The following statement alters the `oe.cust_lname_ix` index so that future data blocks within this index use 5 initial transaction entries:

```
ALTER INDEX oe.cust_lname_ix
    INITTRANS 5;
```

If the `oe.cust_lname_ix` index were partitioned, then this statement would also alter the default attributes of future partitions of the index. Partitions added in the future would then use 5 initial transaction entries and an incremental extent of 100K.

##### **Enabling Parallel Queries: Example**

The following statement sets the parallel attributes for index `upper_ix` (created in "[Creating a Function-Based Index: Example](#)") so that scans on the index will be parallelized:

```
ALTER INDEX upper_ix PARALLEL;
```

##### **Renaming an Index: Example**

The following statement renames an index:

```
ALTER INDEX upper_ix RENAME TO upper_name_ix;
```

##### **Marking an Index Unusable: Examples**

The following statements use the `cost_ix` index, which was created in "[Creating a Range-Partitioned Global Index: Example](#)". Partition `p1` of that index was dropped in "[Dropping an Index Partition: Example](#)". The first statement marks index partition `p2` as `UNUSABLE`:

```
ALTER INDEX cost_ix
    MODIFY PARTITION p2 UNUSABLE;
```

The next statement marks the entire index `cost_ix` as UNUSABLE:

```
ALTER INDEX cost_ix UNUSABLE;
```

### Rebuilding Unusable Index Partitions: Example

The following statements rebuild partitions `p2` and `p3` of the `cost_ix` index, making the index once more usable: The rebuilding of partition `p3` will not be logged:

```
ALTER INDEX cost_ix
    REBUILD PARTITION p2;
ALTER INDEX cost_ix
    REBUILD PARTITION p3 NOLOGGING;
```

### Changing MAXEXTENTS: Example

The following statement changes the maximum number of extents for partition `p3` and changes the logging attribute:

```
/* This example will fail if the tablespace in which partition p3
   resides is locally managed.
*/
ALTER INDEX cost_ix MODIFY PARTITION p3
    STORAGE (MAXEXTENTS 30) LOGGING;
```

### Renaming an Index Partition: Example

The following statement renames an index partition of the `cost_ix` index (created in "[Creating a Range-Partitioned Global Index: Example](#)"):

```
ALTER INDEX cost_ix
    RENAME PARTITION p3 TO p3_Q3;
```

### Splitting a Partition: Example

The following statement splits partition `p2` of index `cost_ix` (created in "[Creating a Range-Partitioned Global Index: Example](#)") into `p2a` and `p2b`:

```
ALTER INDEX cost_ix
    SPLIT PARTITION p2 AT (1500)
        INTO ( PARTITION p2a TABLESPACE tbs_01 LOGGING,
               PARTITION p2b TABLESPACE tbs_02);
```

### Dropping an Index Partition: Example

The following statement drops index partition `p1` from the `cost_ix` index:

```
ALTER INDEX cost_ix
    DROP PARTITION p1;
```

### Modifying Default Attributes: Example

The following statement alters the default attributes of local partitioned index `prod_idx`, which was created in "[Creating an Index on a Hash-Partitioned Table: Example](#)". Partitions added in the future will use 5 initial transaction entries:

```
ALTER INDEX prod_idx
    MODIFY DEFAULT ATTRIBUTES INITTRANS 5;
```

# ALTER INDEXTYPE

## Purpose

Use the `ALTER INDEXTYPE` statement to add or drop an operator of the indextype or to modify the implementation type or change the properties of the indextype.

## Prerequisites

The indextype must be in your own schema or you must have the `ALTER ANY INDEXTYPE` system privilege.

To add a new operator, you must have the `EXECUTE` object privilege on the operator.

To change the implementation type, you must have the `EXECUTE` object privilege on the new implementation type.

## Syntax

`alter_indextype ::=`

(`using_type_clause ::=, storage_table_clause`)

`using_type_clause ::=`

(`array_DML_clause`)

### *array\_DML\_clause*

### *storage\_table\_clause*

## Semantics

### **IF EXISTS**

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### ***schema***

Specify the name of the schema in which the indextype resides. If you omit `schema`, then Oracle Database assumes the indextype is in your own schema.

### ***indextype***

Specify the name of the indextype to be modified.

### **ADD | DROP**

Use the `ADD` or `DROP` clause to add or drop an operator.

No special privilege needed to drop.

- For `schema`, specify the schema containing the operator. If you omit `schema`, then Oracle assumes the operator is in your own schema.
- For `operator`, specify the name of the operator supported by the indextype.  
All the operators listed in this clause must be valid operators.
- For `parameter_type`, list the types of parameters to the operator.

***using\_type\_clause***

The `USING` clause lets you specify a new type to provide the implementation for the `indextype`.

***array\_DML\_clause***

Use this clause to modify the `indextype` to support the array interface for the `ODCIIndexInsert` method.

***type and varray\_type***

If the data type of the column to be indexed is a user-defined object type, then you must specify this clause to identify the varray `varray_type` that Oracle should use to hold column values of `type`. If the `indextype` supports a list of types, then you can specify a corresponding list of varray types. If you omit `schema` for either `type` or `varray_type`, then Oracle assumes the type is in your own schema.

If the data type of the column to be indexed is a built-in system type, then any varray type specified for the `indextype` takes precedence over the ODCI types defined by the system.

**COMPILE**

Use this clause to recompile the `indextype` explicitly. This clause is required only after some upgrade operations, because Oracle Database normally recompiles the `indextype` automatically.

***storage\_table\_clause***

This clause has the same behavior when altering an `indextype` that it has when you are creating an `indextype`. Refer to the `CREATE INDEXTYPE` *storage\_table\_clause* for more information.

**WITH LOCAL PARTITION**

This clause has the same behavior when altering an `indextype` that it has when you create an `indextype`. Refer to the `CREATE INDEXTYPE` clause **WITH LOCAL PARTITION** for more information.

**Examples****Altering an Indextype: Example**

The following example compiles the `position_indextype` `indextype` created in "Creating an Indextype: Example".

```
ALTER INDEXTYPE position_indextype COMPILE;
```

## ALTER INMEMORY JOIN GROUP

**Purpose**

Use the `ALTER INMEMORY JOIN GROUP` statement to add a table column to a join group or remove a table column from a join group.

**See Also:**

- [CREATE INMEMORY JOIN GROUP](#) and [DROP INMEMORY JOIN GROUP](#)
- *Oracle Database In-Memory Guide* for more information on join groups

**Prerequisites**

If the join group is not in your own schema, or if the column you want to add to or remove from the join group is in a table that is not in your own schema, then you must have the `ALTER ANY TABLE` system privilege.

**Syntax**

***alter\_inmemory\_join\_group::=***

**Semantics****IF EXISTS**

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

**schema**

Specify the schema containing the join group. If you omit `schema`, then the database assumes the join group is in your own schema.

**join\_group**

Specify the name of the join group to be modified.

You can view existing join groups by querying the `DBA_JOINGROUPS` or `USER_JOINGROUPS` data dictionary view. Refer to *Oracle Database Reference* for more information on these views.

**ADD**

Specify `ADD` to add a table column to the join group. A join group can contain a maximum of 255 columns.

**REMOVE**

Specify `REMOVE` to remove a table column from the join group. A join group must contain at least 2 columns.

***schema***

Specify the schema of the table that contains the column to be added to or removed from the join group. If you omit *schema*, then Oracle Database assumes the table is in your own schema.

***table***

Specify the name of the table that contains the column to be added to or removed from the join group.

***column***

Specify the name of the column to be added to or removed from the join group.

**Examples**

The following example adds a column to the `prod_id1` join group created in [Examples](#) in the documentation on `CREATE INMEMORY JOIN GROUP`:

```
ALTER INMEMORY JOIN GROUP prod_id1
  ADD(product_descriptions(product_id));
```

The following example removes a column from the `prod_id1` join group:

```
ALTER INMEMORY JOIN GROUP prod_id1
  REMOVE(product_descriptions(product_id));
```

## ALTER JAVA

**Purpose**

Use the `ALTER JAVA` statement to force the resolution of a Java class schema object or compilation of a Java source schema object. (You cannot call the methods of a Java class before all its external references to Java names are associated with other classes.)

**See Also:**

*Oracle Database Java Developer's Guide* for more information on resolving Java classes and compiling Java sources

**Prerequisites**

The Java source or class must be in your own schema, or you must have the `ALTER ANY PROCEDURE` system privilege. You must also have the `EXECUTE` object privilege on Java classes.

## Syntax

***alter\_java::=***

(*invoker\_rights\_clause::=*)

***invoker\_rights\_clause::=***

## Semantics

### IF EXISTS

Specify **IF EXISTS** to alter an existing table.

Specifying **IF NOT EXISTS** with **ALTER VIEW** results in ORA-11544: Incorrect **IF EXISTS** clause for **ALTER/DROP** statement.

### JAVA SOURCE

Use **ALTER JAVA SOURCE** to compile a Java source schema object.

### JAVA CLASS

Use **ALTER JAVA CLASS** to resolve a Java class schema object.

### *object\_name*

Specify a previously created Java class or source schema object. Use double quotation marks to preserve lower- or mixed-case names.

## RESOLVER

The `RESOLVER` clause lets you specify how schemas are searched for referenced fully specified Java names, using the mapping pairs specified when the Java class or source was created.

 **See Also:**

[CREATE JAVA](#) and "[Resolving a Java Class: Example](#)"

## RESOLVE | COMPILE

`RESOLVE` and `COMPILE` are synonymous keywords. They let you specify that Oracle Database should attempt to resolve the primary Java class schema object.

- When applied to a class, resolution of referenced names to other class schema objects occurs.
- When applied to a source, source compilation occurs.

### *invoker\_rights\_clause*

The `invoker_rights_clause` lets you specify whether the methods of the class execute with the privileges and in the schema of the user who defined it or with the privileges and in the schema of `CURRENT_USER`.

This clause also determines how Oracle Database resolves external names in queries, DML operations, and dynamic SQL statements in the member functions and procedures of the type.

### AUTHID CURRENT\_USER

Specify `CURRENT_USER` if you want the methods of the class to execute with the privileges of `CURRENT_USER`. This clause is the default and creates an **invoker-rights class**.

This clause also specifies that external names in queries, DML operations, and dynamic SQL statements resolve in the schema of `CURRENT_USER`. External names in all other statements resolve in the schema in which the methods reside.

### AUTHID DEFINER

Specify `DEFINER` if you want the methods of the class to execute with the privileges of the user who defined the class.

This clause also specifies that external names resolve in the schema where the methods reside.

 **See Also:**

*Oracle Database PL/SQL Language Reference* for information on how `CURRENT_USER` is determined

## Examples

### Resolving a Java Class: Example

The following statement forces the resolution of a Java class:

```
ALTER JAVA CLASS "Agent"
  RESOLVER (("/usr/bin/bfile_dir/*" pm) (* public))
  RESOLVE;
```

# SQL Statements: ALTER LIBRARY to ALTER SESSION

This chapter contains the following SQL statements:

- [ALTER LIBRARY](#)
- [ALTER LOCKDOWN PROFILE](#)
- [ALTER MATERIALIZED VIEW](#)
- [ALTER MATERIALIZED VIEW LOG](#)
- [ALTER MATERIALIZED ZONEMAP](#)
- [ALTER OPERATOR](#)
- [ALTER OUTLINE](#)
- [ALTER PACKAGE](#)
- [ALTER PLUGGABLE DATABASE](#)
- [ALTER PROCEDURE](#)
- [ALTER PROFILE](#)
- [ALTER RESOURCE COST](#)
- [ALTER ROLE](#)
- [ALTER ROLLBACK SEGMENT](#)
- [ALTER SEQUENCE](#)
- [ALTER SESSION](#)

## ALTER LIBRARY

### Purpose

The `ALTER LIBRARY` statement explicitly recompiles a library. Explicit recompilation eliminates the need for implicit run-time recompilation and prevents associated run-time compilation errors and performance overhead.

#### Note:

This statement does not change the declaration or definition of an existing library. To redeclare or redefine a library, use the "[CREATE LIBRARY](#)" with the `OR REPLACE` clause.

## Prerequisites

If the library is in the `SYS` schema, you must be connected as `SYSDBA`. Otherwise, the library must be in your own schema or you must have the `ALTER ANY LIBRARY` system privilege.

## Syntax

`alter_library ::=`

(*library\_compile\_clause*: See *Oracle Database PL/SQL Language Reference* for the syntax of this clause.)

## Semantics

### IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### *schema*

Specify the schema containing the library. If you omit `schema`, then Oracle Database assumes the procedure is in your own schema.

### *library\_name*

Specify the name of the library to be recompiled.

### *library\_compile\_clause*

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling libraries.

### **EDITIONABLE | NONEDITIONABLE**

Use these clauses to specify whether the library becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `LIBRARY` in `schema`. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

# ALTER LOCKDOWN PROFILE

## Purpose

Use the `ALTER LOCKDOWN PROFILE` statement to alter a PDB lockdown profile. You can use PDB lockdown profiles in a multitenant environment to restrict user operations in pluggable databases (PDBs).

Immediately after you create a lockdown profile with the `CREATE LOCKDOWN PROFILE` statement, all user operations are enabled for the profile. You can then use the `ALTER LOCKDOWN PROFILE` statement to disable certain user operations for the profile. When a lockdown profile is applied to a CDB, application container, or PDB, users cannot perform the operations that are disabled for the profile. If you later would like to reenable some of the disabled user operations, you can use the `ALTER LOCKDOWN PROFILE` statement to do so.

The `ALTER LOCKDOWN PROFILE` statement allows you to disable or enable:

- User operations associated with certain database features (using the `lockdown_features` clause)
- User operations associated with certain database options (using the `lockdown_options` clause)
- The issuance of certain SQL statements (using the `lockdown_statements` clause)

### See Also:

- [CREATE LOCKDOWN PROFILE](#) and [DROP LOCKDOWN PROFILE](#)
- [Oracle Database Security Guide](#) for more information on PDB lockdown profiles

## Prerequisites

- You must issue the `ALTER LOCKDOWN PROFILE` statement from the CDB Root or Application Root.
- You must have the `ALTER LOCKDOWN PROFILE` system privilege in the container in which you issue the statement.

## Syntax

`alter_lockdown_profile ::=`

*lockdown\_features ::=*

*lockdown\_options ::=*

*lockdown\_statements ::=*

*statement\_clauses ::=*

### *clause\_options*::=

*option\_values*::=

## Semantics

*profile name*

Specify the name of the PDB lockdown profile to be altered.

You can find the names of existing PDB lockdown profiles by querying the DBA\_LOCKDOWN\_PROFILES data dictionary view.

## *lockdown features*

This clause lets you disable or enable user operations associated with certain database features.

- Specify `DISABLE` to add a restriction for the specified features. Users will be restricted from performing these operations in any PDB to which the profile applies.
  - Specify `ENABLE` to remove a restriction for the specified features. Users will be allowed to perform these operations in any PDB to which the profile applies.
  - Use *feature* to specify the features whose operations you want to disable or enable. [Table 11-1](#) lists the features you can specify and describes the operations associated with each feature. The table also indicates a feature bundle for each feature. For *feature*, you can specify a feature bundle name to disable or enable user operations for all features in that bundle, or you can specify an individual feature name. You can specify feature bundle names and feature names in any combination of uppercase and lowercase letters.
  - Use `ALL` to specify all features listed in the table.

- Use ALL EXCEPT to specify all features listed in the table except the specified features.

If you omit this clause, then the default is ENABLE ALL.

 **Note:**

- The Oracle Text type FILE\_DATASTORE is deprecated. Oracle recommends that you replace FILE\_DATASTORE indexes with the DIRECTORY\_DATASTORE index type for greater security as it enables file access to be based on directory objects.
- The Oracle Text type URL\_DATASTORE is deprecated. Oracle recommends that you replace URL\_DATASTORE with NETWORK\_DATASTORE, which uses ACLs to control access to specific servers.

**Table 11-1 PDB Lockdown Profile Features**

Feature Bundle	Feature	Operations
AWR_ACCESS	AWR_ACCESS	The PDB taking manual and automatic Automatic Workload Repository (AWR) snapshots
COMMON_SCHEMA_ACCESS	COMMON_USER_LOCAL_SCHEMA_ACCESS	A common user invoking an invoker's rights code unit or accessing a BEQUEATH CURRENT_USER view owned by any local user in the PDB
COMMON_SCHEMA_ACCESS	LOCAL_USER_COMMON_SCHEMA_ACCESS	<ul style="list-style-type: none"> <li>• A local user with an ANY system privilege (for example, CREATE ANY TABLE) creating or accessing objects in a common user's schema for which the privilege applies. <b>Note:</b> Disabling the LOCAL_USER_COMMON_SCHEMA_ACCESS feature does not prevent a local user with the SYSDBA privilege or specific object privileges from creating or accessing objects in a common user's schema. Therefore, Oracle recommends against granting such privileges to local users.</li> <li>• A local user with the BECOME USER system privilege becoming a common user</li> <li>• A local user altering a common user by issuing an ALTER USER statement</li> <li>• A local user using a common user for proxy connections</li> </ul>

**Table 11-1 (Cont.) PDB Lockdown Profile Features**

Feature Bundle	Feature	Operations
COMMON_SCHEMA_ACCESS	SECURITY_POLICIES	<p>Creation of certain security policies by a local user on a common object, including:</p> <ul style="list-style-type: none"> <li>• Data Redaction</li> <li>• Fine Grained Auditing (FGA)</li> <li>• Real Application Security (RAS)</li> <li>• Virtual Private Database (VPD)</li> </ul>
CONNECTIONS	COMMON_USER_CONNECT	A common user connecting to the PDB directly. If this feature is disabled, then in order to connect to the PDB, a common user must first connect to the CDB root and then switch to the desired PDB using the <code>ALTER SESSION SET CONTAINER</code> statement.
CONNECTIONS	LOCAL_SYSOPER_RESTRICTED_MODE_CONNECT	A local user with the <code>SYSOPER</code> privilege connecting to a PDB that is open in RESTRICTED mode
CTX_LOGGING	CTX_LOGGING	Use logging in Oracle Text PL/SQL procedures such as <code>CTX_OUTPUT.START_LOG</code> and <code>CTX_OUTPUT.START_QUERY_LOG</code>
JAVA	JAVA	Java as a whole. If this feature is disabled, then all options and features of the database that depend on Java will be disabled.
JAVA_RUNTIME	JAVA_RUNTIME	Operations through Java that require <code>java.lang.RuntimePermission</code>
NETWORK_ACCESS	AQ_PROTOCOLS	Using HTTP, SMTP, and OCI notification features.

**Table 11-1 (Cont.) PDB Lockdown Profile Features**

Feature Bundle	Feature	Operations
NETWORK_ACCESS	CTX_PROTOCOLS	<ul style="list-style-type: none"> <li>Operations that access the Oracle Text datastore types DIRECTORY_DATASTORE and NETWORK_DATASTORE.</li> </ul> <p>The type DIRECTORY_DATASTORE has an attribute called DIRECTORY which is the directory object whose data is to be indexed. The default value of this attribute is null.</p> <p>The DIRECTORY_DATASTORE type replaces the FILE_DATASTORE type, which is deprecated.</p> <p>The NETWORK_DATASTORE type replaces the URL_DATASTORE type, which is deprecated.</p> <p>The type NETWORK_DATASTORE conforms to the standard database security model for providing URL access based on access control lists (ACLs), which support the HTTP and HTTPS protocols.</p> <p>The URL_DATASTORE type did not support HTTPS.</p> <ul style="list-style-type: none"> <li>Printing tokens as part of CTX logging with events EVENT_INDEX_PRINT_TOKEN and EVENT_OPT_PRINT_TOKEN</li> </ul>
NETWORK_ACCESS	DBMS_DEBUG_JDWP	Using the DBMS_DEBUG_JDWP PL/SQL package
NETWORK_ACCESS	UTL_HTTP	Using the UTL_HTTP PL/SQL package
NETWORK_ACCESS	UTL_INADDR	Using the UTL_INADDR PL/SQL package
NETWORK_ACCESS	UTL_SMTP	Using the UTL_SMTP PL/SQL package
NETWORK_ACCESS	UTL_TCP	Using the UTL_TCP PL/SQL package
NETWORK_ACCESS	XDB_PROTOCOLS	Using HTTP, FTP, and other network protocols through XDB
OS_ACCESS	DROP_TABLESPACE_KEEP_DATAFILES	Dropping a tablespace in the PDB without specifying the INCLUDING CONTENTS AND DATAFILES clause in DROP TABLESPACE statement
OS_ACCESS	EXTERNAL_FILE_ACCESS	Using external files or directory objects in the PDB when PATH_PREFIX is not set for the PDB
OS_ACCESS	EXTERNAL PROCEDURES	Using external procedure agent extproc in the PDB
OS_ACCESS	FILE_TRANSFER	Using the DBMS_FILE_TRANSFER package

**Table 11-1 (Cont.) PDB Lockdown Profile Features**

<b>Feature Bundle</b>	<b>Feature</b>	<b>Operations</b>
OS_ACCESS	JAVA_OS_ACCESS	Using java.io.FilePermission from Java
OS_ACCESS	LOB_FILE_ACCESS	Using BFILE and CFILE data types
OS_ACCESS	TRACE_VIEW_ACCESS	Using the following trace views: <ul style="list-style-type: none"> <li>• [G]V\$DIAG_OPT_TRACE_RECORDS</li> <li>• [G]V\$DIAG_SQL_TRACE_RECORDS</li> <li>• [G]V\$DIAG_TRACE_FILE_CONTENTS</li> <li>• V\$DIAG_SESS_OPT_TRACE_RECORDS</li> <li>• V\$DIAG_SESS_SQL_TRACE_RECORDS</li> </ul>
OS_ACCESS	UTL_FILE	Using UTL_FILE. If this feature is disabled, then the database blocks use of the UTL_FILE.FOPEN function.

***lockdown\_options***

This clause lets you disable or enable user operations associate with certain database options.

- Specify `DISABLE` to disable user operations for the specified options. Users will be restricted from performing these operations in any PDB to which the profile applies.
- Specify `ENABLE` to enable user operations for the specified options. Users will be allowed to perform these operations in any PDB to which the profile applies.
- For *option*, you can specify the following database options in any combination of uppercase and lowercase letters:
  - DATABASE QUEUING – Represents user operations associated with the Oracle Database Advanced Queuing option
  - PARTITIONING – Represents user operations associated with the Oracle Partitioning option
- Use `ALL` to specify all options in the preceding list.
- Use `ALL EXCEPT` to specify all options in the preceding list except the specified options.

If you omit this clause, then the default is `ENABLE OPTION ALL`.

***lockdown\_statements***

This clause lets you disable or enable the issuance of certain SQL statements.

- Specify `DISABLE` to disable the issuance of the specified SQL statements. Users will be restricted from issuing these statements in any PDB to which the profile applies.
- Specify `ENABLE` to enable the issuance of the specified SQL statements. Users will be allowed to issue these statements in any PDB to which the profile applies.
- For *SQL\_statement*, you can specify the following statements in any combination of uppercase and lowercase letters:
  - ADMINISTER KEY MANAGEMENT

- ALTER DATABASE
  - ALTER PLUGGABLE DATABASE
  - ALTER SESSION
  - ALTER SYSTEM
  - ALTER TABLE
  - ALTER INDEX
  - ALTER TABLESPACE
  - ALTER PROFILE
  - CREATE TABLE
  - CREATE INDEX
  - CREATE TABLESPACE
  - CREATE PROFILE
  - CREATE DATABASE LINK
  - DROP TABLE
  - DROP INDEX
  - DROP TABLESPACE
  - DROP PROFILE
- Use ALL to specify all statements in the preceding list.
  - Use ALL EXCEPT to specify all statements in the preceding list except the specified statements.

If you omit this clause, then the default is ENABLE STATEMENT ALL.

#### ***statement\_clauses***

This clause lets you disable or enable specific clauses of the specified SQL statement.

- Use *clause* to specify the SQL keywords that form the clause you want to disable or enable. You can specify a clause in any combination of uppercase and lowercase letters.
- Use ALL to specify all clauses for the SQL statement.
- Use ALL EXCEPT to specify all clauses for the SQL statement except the specified clauses.

For *clause*, you must specify at least enough keywords to unambiguously identify a single clause for the SQL statement. The following are some examples of how to specify *clause* for the ALTER SYSTEM statement:

- To specify the *archive\_log\_clause::=*, specify ARCHIVE. This is sufficient because no other ALTER SYSTEM clause begins with the keyword ARCHIVE. Alternatively, you can specify ARCHIVE LOG for semantic clarity, but the LOG keyword is unnecessary.
- To specify either of the *rolling\_migration\_clauses::=*, you must specify START ROLLING MIGRATION or STOP ROLLING MIGRATION in order to distinguish these clauses from the similarly named *rolling\_patch\_clauses::=* START ROLLING PATCH and STOP ROLLING PATCH.

- You cannot specify the single keyword FLUSH, because several ALTER SYSTEM clauses begin with this keyword. You must instead specify each clause separately, such as FLUSH SHARED\_POOL or FLUSH GLOBAL CONTEXT.

There is no need to specify optional keywords within a clause, because they have no effect. For example:

- The *archive\_log\_clause ::=* has an optional INSTANCE keyword. However, you cannot enable or disable only ARCHIVE LOG clauses that contain the INSTANCE keyword. Specifying ARCHIVE LOG INSTANCE is equivalent to specifying ARCHIVE or ARCHIVE LOG.

There is no need to specify parameter values within a clause, because they have no effect. For example:

- The *shutdown\_dispatcher\_clause ::=* requires you to specify a *dispatcher\_name*. However, you cannot enable or disable SHUTDOWN clauses that contain a specific dispatcher name. Specifying SHUTDOWN dispatcher1 is equivalent to specifying SHUTDOWN.

#### See Also:

[ALTER DATABASE](#), [ALTER PLUGGABLE DATABASE](#), [ALTER SESSION](#), and [ALTER SYSTEM](#) for complete information on the clauses for these statements

### *clause\_options*

This clause is valid only when you specify one of the following for *lockdown\_statements* and *statement\_clauses*:

```
{ DISABLE | ENABLE } STATEMENT = ('ALTER SESSION') CLAUSE = ('SET')
{ DISABLE | ENABLE } STATEMENT = ('ALTER SYSTEM') CLAUSE = ('SET')
```

This clause lets you disable or enable the setting or modification of specific options with the ALTER SESSION SET or ALTER SYSTEM SET statements.

- Use *clause\_option* to specify the option you want to disable or enable.
- Use *clause\_option\_pattern* to specify a pattern that matches multiple options. Within the pattern, specify a percent sign (%) to match zero or more characters in an option name. For example, specifying 'QUERY\_REWRITE %' is equivalent to specifying both the QUERY\_REWRITE\_ENABLED and QUERY\_REWRITE\_INTEGRITY options.
- You can specify *clause\_option* and *clause\_option\_pattern* in any combination of uppercase and lowercase letters.
- Use ALL to specify all options.
- Use ALL EXCEPT to specify all options except the specified options.

 **See Also:**

The [alter\\_session\\_set\\_clause](#) clause of ALTER SESSION and the [alter\\_system\\_set\\_clause](#) clause of ALTER SYSTEM for complete information on the options you can specify for these statements

### **option\_values**

This clause is valid only when you specify one of the following for *lockdown\_statements*, *statement\_clauses*, and *clause\_options*:

```
DISABLE STATEMENT = ('ALTER SESSION') CLAUSE = ('SET') OPTION =
clause_option
DISABLE STATEMENT = ('ALTER SYSTEM') CLAUSE = ('SET') OPTION =
clause_option
```

This clause lets you specify a default value for an option when disabling the setting of that option. For options that take numeric values, this clause also lets you restrict users from setting an option to certain values.

- The `VALUE` clause lets you specify a default *option\_value* for *clause\_option*, which will go into effect for any PDB to which the profile applies after you close and reopen the PDB. If *clause\_option* accepts multiple default values, then you can specify more than one *option\_value* in a comma-separated list. The purpose of using this clause is to simultaneously set a default value for an option and restrict users from setting or modifying the value.
- The `MINVALUE` clause lets you restricts users from setting the value of *clause\_option* to a value less than *option\_value*. You can specify this clause only for options that take a numeric value.
- The `MAXVALUE` clause lets you restricts users from setting the value of *clause\_option* to a value greater than *option\_value*. You can specify this clause only for options that take a numeric value.
- You can specify both the `MINVALUE` and `MAXVALUE` clauses together to restrict users from setting the value of *clause\_options* to any value less than `MINVALUE` or greater than `MAXVALUE`.
- `MINVALUE` and `MAXVALUE` settings take effect immediately when the lockdown profile is assigned to a PDB; you need not close and reopen the PDB.

 **See Also:**

[Oracle Database Reference](#) for complete information on the values allowed for the various options

### **USERS Clause**

As a CDB administrator or an Application administrator you can use the `USERS` clause to configure lockdown rules for a specific set of users.

The values for `USERS` in a `CDB$ROOT` lockdown profile are as follows:

- `USERS = ALL` means that the lockdown rule applies to all users in the PDB.
- `USERS = COMMON` means that the lockdown rule applies only to CDB `COMMON` users in the PDB.
- `USERS = LOCAL` means that the lockdown rule applies only to local users in the PDB.  
Application common users are considered local users at the CDB level.

The values for `USERS` in an Application `ROOT` lockdown profile are as follows:

- `USERS = ALL` means that the lockdown rule applies to all users in the PDB.
- `USERS = COMMON` means that the lockdown rule applies only to Application `COMMON` users in the PDB.
- `USERS = LOCAL` means that the lockdown rule applies only to local users in the PDB.

Note that the Application lockdown profile rules should not affect CDB common users.

- `ALL` users means Application common users and local users in the PDB.
- `COMMON` users means Application common users in the PDB.

## Examples

The following statement creates PDB lockdown profile `hr_prof`:

```
CREATE LOCKDOWN PROFILE hr_prof;
```

The remaining examples in this section alter `hr_prof`.

### Disabling Features for PDB Lockdown Profiles: Examples

The following statement disables all features in the feature bundle `NETWORK_ACCESS`:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE FEATURE = ('NETWORK_ACCESS');
```

The following statement disables the `LOB_FILE_ACCESS` and `TRACE_VIEW_ACCESS` features:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE FEATURE = ('LOB_FILE_ACCESS', 'TRACE_VIEW_ACCESS');
```

The following statement disables all features except the `COMMON_USER_LOCAL_SCHEMA_ACCESS` and `LOCAL_USER_COMMON_SCHEMA_ACCESS` features:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE FEATURE ALL EXCEPT = ('COMMON_USER_LOCAL_SCHEMA_ACCESS',
    'LOCAL_USER_COMMON_SCHEMA_ACCESS');
```

The following statement disables all features:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE FEATURE ALL;
```

### Enabling Features for PDB Lockdown Profiles: Examples

The following statement enables the UTL\_HTTP and UTL\_SMTP features, as well as all features in the feature bundle OS\_ACCESS:

```
ALTER LOCKDOWN PROFILE hr_prof
ENABLE FEATURE = ('UTL_HTTP', 'UTL_SMTP', 'OS_ACCESS');
```

The following statement enables all features except the AQ\_PROTOCOLS and CTX\_PROTOCOLS features:

```
ALTER LOCKDOWN PROFILE hr_prof
ENABLE FEATURE ALL EXCEPT = ('AQ_PROTOCOLS', 'CTX_PROTOCOLS');
```

The following statement enables all features:

```
ALTER LOCKDOWN PROFILE hr_prof
ENABLE FEATURE ALL;
```

### Disabling Options for PDB Lockdown Profiles: Examples

The following statement disables user operations associated with the Oracle Database Advanced Queuing option:

```
ALTER LOCKDOWN PROFILE hr_prof
DISABLE OPTION = ('DATABASE QUEUING');
```

The following statement disables user operations associated with the Oracle Partitioning option:

```
ALTER LOCKDOWN PROFILE hr_prof
DISABLE OPTION = ('PARTITIONING');
```

### Enabling Options for PDB Lockdown Profiles: Examples

The following statement enables user operations associated with the Oracle Database Advanced Queuing option:

```
ALTER LOCKDOWN PROFILE hr_prof
ENABLE OPTION = ('DATABASE QUEUING');
```

The following statement enables user operations associated both with the Oracle Database Advanced Queuing option and the Oracle Partitioning option:

```
ALTER LOCKDOWN PROFILE hr_prof
ENABLE OPTION ALL;
```

### Disabling SQL Statements for PBB Lockdown Profiles: Examples

The following statement disables the ALTER DATABASE statement:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER DATABASE');
```

The following statement disables the ALTER SYSTEM SUSPEND and ALTER SYSTEM RESUME statements:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER SYSTEM')
    CLAUSE = ('SUSPEND', 'RESUME');
```

The following statement disables all clauses of the ALTER PLUGGABLE DATABASE statement, except DEFAULT TABLESPACE and DEFAULT TEMPORARY TABLESPACE:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER PLUGGABLE DATABASE')
    CLAUSE ALL EXCEPT = ('DEFAULT TABLESPACE', 'DEFAULT TEMPORARY
  TABLESPACE');
```

The following statement disables using the ALTER SESSION statement to set or modify COMMIT\_WAIT or CURSOR\_SHARING:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER SESSION')
    CLAUSE = ('SET')
      OPTION = ('COMMIT_WAIT', 'CURSOR_SHARING');
```

The following statement disables using the ALTER SYSTEM statement to set or modify the value of PDB\_FILE\_NAME\_CONVERT. It also sets the default value for PDB\_FILE\_NAME\_CONVERT to 'cdb1\_pdb0', 'cdb1\_pdb1'. This default value will take effect the next time the PDB is closed and reopened.

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER SYSTEM')
    CLAUSE = ('SET')
      OPTION = ('PDB_FILE_NAME_CONVERT')
        VALUE = ('cdb1_pdb0', 'cdb1_pdb1');
```

The following statement disables using the ALTER SYSTEM statement to set or modify the value of CPU\_COUNT to a value less than 8:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER SYSTEM')
    CLAUSE = ('SET')
      OPTION = ('CPU_COUNT')
        MINVALUE = '8';
```

The following statement disables using the ALTER SYSTEM statement to set or modify the value of CPU\_COUNT to a value greater than 2:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER SYSTEM')
    CLAUSE = ('SET')
      OPTION = ('CPU_COUNT')
        MAXVALUE = '2';
```

The following statement disables using the ALTER SYSTEM statement to set or modify the value of CPU\_COUNT to a value less than 2 or greater than 6:

```
ALTER LOCKDOWN PROFILE hr_prof
  DISABLE STATEMENT = ('ALTER SYSTEM')
    CLAUSE = ('SET')
      OPTION = ('CPU_COUNT')
        MINVALUE = '2'
        MAXVALUE = '6';
```

### Enabling SQL Statements for PBB Lockdown Profiles: Examples

The following statement enables all statements except ALTER DATABASE:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE STATEMENT ALL EXCEPT = ('ALTER DATABASE');
```

The following statement enables the ALTER DATABASE MOUNT and ALTER DATABASE OPEN statements:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE STATEMENT = ('ALTER DATABASE')
    CLAUSE = ('MOUNT', 'OPEN');
```

The following statement enables all clauses of the ALTER PLUGGABLE DATABASE statement, except DEFAULT TABLESPACE and DEFAULT TEMPORARY TABLESPACE:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE STATEMENT = ('ALTER PLUGGABLE DATABASE')
    CLAUSE ALL EXCEPT = ('DEFAULT TABLESPACE', 'DEFAULT TEMPORARY
TABLESPACE');
```

The following statement enables using the ALTER SESSION statement to set or modify COMMIT\_WAIT or CURSOR\_SHARING:

```
ALTER LOCKDOWN PROFILE hr_prof
  ENABLE STATEMENT = ('ALTER SESSION')
    CLAUSE = ('SET')
      OPTION = ('COMMIT_WAIT', 'CURSOR_SHARING');
```

# ALTER MATERIALIZED VIEW

## Purpose

A materialized view is a database object that contains the results of a query. The `FROM` clause of the query can name tables, views, and other materialized views. Collectively these source objects are called **master tables** (a replication term) or **detail tables** (a data warehousing term). This reference uses the term master tables for consistency. The databases containing the master tables are called the **master databases**.

Use the `ALTER MATERIALIZED VIEW` statement to modify an existing materialized view in one or more of the following ways:

- To change its storage characteristics
- To change its refresh method, mode, or time
- To alter its structure so that it is a different type of materialized view
- To enable or disable query rewrite

### Note:

The keyword `SNAPSHOT` is supported in place of `MATERIALIZED VIEW` for backward compatibility.

### See Also:

- [CREATE MATERIALIZED VIEW](#) for more information on creating materialized views
- *Oracle Database Administrator's Guide* for information on materialized views in a replication environment
- *Oracle Database Data Warehousing Guide* for information on materialized views in a data warehousing environment

## Prerequisites

The materialized view must be in your own schema, or you must have the `ALTER ANY MATERIALIZED VIEW` system privilege.

To enable a materialized view for query rewrite:

- If all of the master tables in the materialized view are in your schema, then you must have the `QUERY REWRITE` privilege.
- If any of the master tables are in another schema, then you must have the `GLOBAL QUERY REWRITE` privilege.
- If the materialized view is in another user's schema, then both you and the owner of that schema must have the appropriate `QUERY REWRITE` privilege, as described in the

preceding two items. In addition, the owner of the materialized view must have SELECT access to any master tables that the materialized view owner does not own.

To specify an edition in the `evaluation_edition_clause` or the `unusable_editions_clause`, you must have the `USE` privilege on the edition.

## Syntax

***alter\_materialized\_view::=***

(physical\_attributes\_clause ::=, modify\_mv\_column\_clause ::=, table\_compression ::=, inmemory\_table\_clause ::=, LOB\_storage\_clause ::=, modify\_LOB\_storage\_clause ::=, alter\_table\_partitioning ::= (part of ALTER TABLE), parallel\_clause ::=, logging\_clause ::=, allocate\_extent\_clause ::=, deallocate\_unused\_clause ::=, shrink\_clause ::=, alter\_iot\_clauses ::=, scoped\_table\_ref\_constraint ::=, alter\_mv\_refresh ::=, evaluation\_edition\_clause ::=, alter\_query\_rewrite\_clause ::=, annotations\_clause)

**physical\_attributes\_clause ::=**

***alter\_query\_rewrite\_clause ::=***

**Note:**

You cannot specify only QUERY REWRITE. You must specify at least one of the following: ENABLE, DISABLE, or a subclause of the unusable\_editions\_clause.

***unusable\_editions\_clause::=***

## Semantics

### IF EXISTS

Specify `IF EXISTS` to alter an existing materialized view.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### *schema*

Specify the schema containing the materialized view. If you omit `schema`, then Oracle Database assumes the materialized view is in your own schema.

### *materialized\_view*

Specify the name of the materialized view to be altered.

### *physical\_attributes\_clause*

Specify new values for the `PCTFREE`, `PCTUSED`, and `INITRANS` parameters (or, when used in the `USING INDEX` clause, for the `INITRANS` parameter only) and the storage characteristics for the materialized view. Refer to [ALTER TABLE](#) for information on the `PCTFREE`, `PCTUSED`, and `INITRANS` parameters and to [storage\\_clause](#) for information about storage characteristics.

### *modify\_mv\_column\_clause*

Use this clause to encrypt or decrypt this column of the materialized view. Refer to the `CREATE TABLE` clause [encryption\\_spec](#) for information on this clause.

### *table\_compression*

Use the `table_compression` clause to instruct Oracle Database whether to compress data segments to reduce disk and memory use. Refer to the `table_compression` clause of `CREATE TABLE` for the full semantics of this clause.

### *inmemory\_table\_clause*

Use the `inmemory_table_clause` to enable or disable the materialized view or its columns for the In-Memory Column Store (IM column store), or to change the In-Memory attributes for the materialized view or its columns. This clause has the same semantics here as it has for the

ALTER TABLE statement. Refer to the [inmemory\\_table\\_clause](#) of ALTER TABLE for the full semantics of this clause.

#### ***LOB\_storage\_clause***

The *LOB\_storage\_clause* lets you specify the storage characteristics of a new LOB. LOB storage behaves for materialized views exactly as it does for tables. Refer to the [LOB\\_storage\\_clause](#) (in CREATE TABLE) for information on the LOB storage parameters.

#### ***modify\_LOB\_storage\_clause***

The *modify\_LOB\_storage\_clause* lets you modify the physical attributes of the LOB attribute *LOB\_item* or the LOB object attribute. Modification of LOB storage behaves for materialized views exactly as it does for tables.

#### **See Also:**

The [modify\\_LOB\\_storage\\_clause](#) of ALTER TABLE for information on the LOB storage parameters that can be modified

#### ***alter\_table\_partitioning***

The syntax and general functioning of the partitioning clauses for materialized views is the same as for partitioned tables. Refer to [alter\\_table\\_partitioning](#) in the documentation on ALTER TABLE.

#### **Restriction on Altering Materialized View Partitions**

You cannot specify the *LOB\_storage\_clause* or *modify\_LOB\_storage\_clause* within any of the *partitioning\_clauses*.

#### **Note:**

If you want to keep the contents of the materialized view synchronized with those of the master table, then Oracle recommends that you manually perform a complete refresh of all materialized views dependent on the table after dropping or truncating a table partition.

#### **MODIFY PARTITION UNUSABLE LOCAL INDEXES**

Use this clause to mark `UNUSABLE` all the local index partitions associated with *partition*.

#### **MODIFY PARTITION REBUILD UNUSABLE LOCAL INDEXES**

Use this clause to rebuild the unusable local index partitions associated with *partition*.

***parallel\_clause***

The *parallel\_clause* lets you change the default degree of parallelism for the materialized view.

For complete information on this clause, refer to [parallel\\_clause](#) in the documentation on CREATE TABLE.

***logging\_clause***

Specify or change the logging characteristics of the materialized view. Refer to the [logging\\_clause](#) for a full description of this clause.

***allocate\_extent\_clause***

The *allocate\_extent\_clause* lets you explicitly allocate a new extent for the materialized view. Refer to the [allocate\\_extent\\_clause](#) for a full description of this clause.

***deallocate\_unused\_clause***

Use the *deallocate\_unused\_clause* to explicitly deallocate unused space at the end of the materialized view and make the freed space available for other segments. Refer to the [deallocate\\_unused\\_clause](#) for a full description of this clause.

***shrink\_clause***

Use this clause to compact the materialized view segments. For complete information on this clause, refer to [shrink\\_clause](#) in the documentation on CREATE TABLE.

**CACHE | NOCACHE**

For data that will be accessed frequently, CACHE specifies that the blocks retrieved for this table are placed at the most recently used end of the LRU list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables. NOCACHE specifies that the blocks are placed at the least recently used end of the LRU list. Refer to "[CACHE | NOCACHE | CACHE READS](#)" in the documentation on CREATE TABLE for more information about this clause.

***annotations\_clause***

The *annotation\_name* is an identifier that can have up to 4000 characters. If the annotation name is a reserved word it must be provided in double quotes. When a double quoted identifier is used, the identifier can also contain whitespace characters. However, identifiers that contain only whitespace characters are not accepted.

You can only change annotations at the view level with the ALTER statement. To drop column-level annotations, you must drop and recreate the view.

For the full semantics of the annotations clause see [annotations\\_clause](#) of CREATE TABLE.

***alter\_iot\_clauses***

Use the *alter\_iot\_clauses* to change the characteristics of an index-organized materialized view. The keywords and parameters of the components of the *alter\_iot\_clauses* have the same semantics as in ALTER TABLE, with the restrictions that follow.

**Restrictions on Altering Index-Organized Materialized Views**

You cannot specify the `mapping_table_clause` or the `prefix_compression` clause of the `index_org_table_clause`.

 **See Also:**

[index\\_org\\_table\\_clause](#) of CREATE MATERIALIZED VIEW for information on creating an index-organized materialized view

### USING INDEX Clause

Use this clause to change the value of `INITRANS` and `STORAGE` parameters for the index Oracle Database uses to maintain the materialized view data.

#### Restriction on the USING INDEX clause

You cannot specify the `PCTUSED` or `PCTFREE` parameters in this clause.

### MODIFY scoped\_table\_ref\_constraint

Use the `MODIFY scoped_table_ref_constraint` clause to rescope a `REF` column or attribute to a new table or to an alias for a new column.

#### Restrictions on Rescoping REF Columns

You can rescope only one `REF` column or attribute in each `ALTER MATERIALIZED VIEW` statement, and this must be the only clause in this statement.

### `alter_mv_refresh`

Use the `alter_mv_refresh` clause to change the default method and mode and the default times for automatic refreshes. If the contents of the master tables of a materialized view are modified, then the data in the materialized view must be updated to make the materialized view accurately reflect the data currently in its master table(s). This clause lets you schedule the times and specify the method and mode for Oracle Database to refresh the materialized view.

 **See Also:**

- This clause only sets the default refresh options. For instructions on actually implementing the refresh, refer to *Oracle Database Administrator's Guide* and *Oracle Database Data Warehousing Guide*.
- *Oracle Database Data Warehousing Guide* to learn how to use refresh statistics to monitor the performance of materialized view refresh operations

### FAST Clause

Specify `FAST` for the fast refresh method, which performs the refresh according to the changes that have occurred to the master tables. The changes are stored either in the materialized view log associated with the master table (for conventional DML changes) or in the direct loader log (for direct-path `INSERT` operations).

For both conventional DML changes and for direct-path `INSERT` operations, other conditions may restrict the eligibility of a materialized view for fast refresh.

When you change the refresh method to `FAST` in an `ALTER MATERIALIZED VIEW` statement, Oracle Database does not perform this verification. If the materialized view is not eligible for fast refresh, then Oracle Database returns an error when you attempt to refresh this view.

#### See Also:

- *Oracle Database Administrator's Guide* for restrictions on fast refresh in replication environments
- *Oracle Database Data Warehousing Guide* for restrictions on fast refresh in data warehouse environments
- "[Automatic Refresh: Examples](#)"

#### **COMPLETE Clause**

Specify `COMPLETE` for the complete refresh method, which is implemented by executing the defining query of the materialized view. If you specify a complete refresh, then Oracle Database performs a complete refresh even if a fast refresh is possible.

#### See Also:

- "[Complete Refresh: Example](#)"

#### **FORCE Clause**

Specify `FORCE` if, when a refresh occurs, you want Oracle Database to perform a fast refresh if one is possible or a complete refresh otherwise.

#### **ON COMMIT Clause**

Specify `ON COMMIT` if you want a refresh to occur whenever Oracle Database commits a transaction that operates on a master table of the materialized view.

You cannot specify both `ON COMMIT` and `ON DEMAND`. If you specify `ON COMMIT`, then you cannot also specify `START WITH` or `NEXT`.

#### **Restriction on ON COMMIT**

This clause is supported only for materialized join views and single-table materialized aggregate views.

#### **ON DEMAND Clause**

Specify `ON DEMAND` if you want the materialized view to be refreshed on demand by calling one of the three `DBMS_MVIEW` refresh procedures. If you omit both `ON COMMIT` and `ON DEMAND`, then `ON DEMAND` is the default.

You cannot specify both ON COMMIT and ON DEMAND. START WITH and NEXT take precedence over ON DEMAND. Therefore, in most circumstances it is not meaningful to specify ON DEMAND when you have specified START WITH or NEXT.

#### See Also:

- *Oracle Database PL/SQL Packages and Types Reference* for information on these procedures
- *Oracle Database Data Warehousing Guide* on the types of materialized views you can create by specifying REFRESH ON DEMAND

### **START WITH Clause**

Specify START WITH *date* to indicate a date for the first automatic refresh time.

### **NEXT Clause**

Specify NEXT to indicate a date expression for calculating the interval between automatic refreshes.

Both the START WITH and NEXT values must evaluate to a time in the future. If you omit the START WITH value, then Oracle Database determines the first automatic refresh time by evaluating the NEXT expression with respect to the creation time of the materialized view. If you specify a START WITH value but omit the NEXT value, then Oracle Database refreshes the materialized view only once. If you omit both the START WITH and NEXT values, or if you omit the *alter\_mv\_refresh* entirely, then Oracle Database does not automatically refresh the materialized view.

### **WITH PRIMARY KEY Clause**

Specify WITH PRIMARY KEY to change a rowid materialized view to a primary key materialized view. Primary key materialized views allow materialized view master tables to be reorganized without affecting the ability of the materialized view to continue to fast refresh.

For you to specify this clause, the master table must contain an enabled primary key constraint and must have defined on it a materialized view log that logs primary key information.

#### See Also:

- *Oracle Database Administrator's Guide* for detailed information about primary key materialized views
- "[Primary Key Materialized View: Example](#)"

### **USING ROLLBACK SEGMENT Clause**

This clause is not valid if your database is in automatic undo mode, because in that mode Oracle Database uses undo tablespaces instead of rollback segments. Oracle strongly recommends that you use automatic undo mode. This clause is supported for

backward compatibility with replication environments containing older versions of Oracle Database that still use rollback segments.

For complete information on this clause, refer to [CREATE MATERIALIZED VIEW ... "USING ROLLBACK SEGMENT Clause"](#).

### USING ... CONSTRAINTS Clause

This clause has the same semantics in [CREATE MATERIALIZED VIEW](#) and [ALTER MATERIALIZED VIEW](#) statements. For complete information, refer to "[USING ... CONSTRAINTS Clause](#)" in the documentation on [CREATE MATERIALIZED VIEW](#).

#### *evaluation\_edition\_clause*

Use this clause to change the evaluation edition for the materialized view. This clause has the same semantics in [CREATE MATERIALIZED VIEW](#) and [ALTER MATERIALIZED VIEW](#) statements. For complete information on this clause, refer to [evaluation\\_edition\\_clause](#) in the documentation on [CREATE MATERIALIZED VIEW](#).

#### Notes on Changing the Evaluation Edition of a Materialized View

The following notes apply when changing the evaluation edition of a materialized view:

- If you change the evaluation edition of a refresh-on-commit materialized view, then Oracle Database performs a complete refresh of the materialized view unless you specify `CONSIDER FRESH`.
- If you change the evaluation edition of a refresh-on-demand materialized view, then Oracle Database sets the staleness state of the materialized view to `STALE` unless you specify `CONSIDER FRESH`.
- For both refresh-on-commit and refresh-on-demand materialized views: If you change the evaluation edition and specify `CONSIDER FRESH`, then Oracle Database does not update the staleness state of the materialized view and does not rebuild the materialized view. Therefore, you can specify `CONSIDER FRESH` to indicate that, although the evaluation edition has changed, there is no difference in the results that `subquery` will produce. If the materialized view is stale and in need of either a fast refresh or a complete refresh before this statement is issued, then the state will not be changed and the materialized view may contain bad data.

#### { ENABLE | DISABLE } ON QUERY COMPUTATION

This clause lets you control whether the materialized view is a real-time materialized view or a regular materialized view.

- Specify `ENABLE ON QUERY COMPUTATION` to convert a regular materialized view into a real-time materialized view by enabling on-query computation.
- Specify `DISABLE ON QUERY COMPUTATION` to convert a real-time materialized view into a regular materialized view by disabling on-query computation.

This clause has the same semantics in [CREATE MATERIALIZED VIEW](#) and [ALTER MATERIALIZED VIEW](#) statements. For complete information on this clause, refer to [{ ENABLE | DISABLE } ON QUERY COMPUTATION](#) in the documentation on [CREATE MATERIALIZED VIEW](#).

#### *alter\_query\_rewrite\_clause*

Use this clause to specify whether the materialized view is eligible to be used for query rewrite.

## ENABLE Clause

Specify `ENABLE` to enable the materialized view for query rewrite. If you currently specify, or previously specified, the `unusable_editions_clause` for the materialized view, then it is not enabled for query rewrite in the unusable editions.

### See Also:

- "[Enabling Query Rewrite: Example](#)"
- *Oracle Database Data Warehousing Guide* to learn how to use refresh statistics to monitor the performance of materialized view refresh operations

## Restrictions on Enabling Materialized Views

Enabling materialized views is subject to the following restrictions:

- If the materialized view is in an invalid or unusable state, then it is not eligible for query rewrite in spite of the `ENABLE` mode.
- You cannot enable query rewrite if the materialized view was created totally or in part from a view.
- You can enable query rewrite only if all user-defined functions in the materialized view are `DETERMINISTIC`.

### See Also:

#### [CREATE FUNCTION](#)

- You can enable query rewrite only if expressions in the statement are repeatable. For example, you cannot include `CURRENT_TIME` or `USER`.

### See Also:

*Oracle Database Data Warehousing Guide* for more information on query rewrite

## DISABLE Clause

Specify `DISABLE` if you do not want the materialized view to be eligible for use by query rewrite. If a materialized view is in the invalid state, then it is not eligible for use by query rewrite, whether or not it is disabled. However, a disabled materialized view can be refreshed.

### *unusable\_editions\_clause*

Use this clause to specify the editions in which the materialized view is not eligible for query rewrite. This clause has the same semantics in `CREATE MATERIALIZED VIEW` and

ALTER MATERIALIZED VIEW statements. For complete information on this clause, refer to [unusable\\_editions\\_clause](#) in the documentation on CREATE MATERIALIZED VIEW.

Cursors that use the materialized view for query rewrite and were compiled in an edition that is made unusable will be invalidated.

#### ENABLE | DISABLE CONCURRENT REFRESH

Enable concurrent refresh to refresh the same on-commit atomic materialized view across multiple sessions. Multiple sessions which have DML on a base table can refresh the MV concurrently. There are no limitations on how many materialized views can be refreshed.

Concurrent refresh is disabled by default. You must explicitly enable it on the materialized view. Note that you can enable it only on on-commit materialized views.

#### See Also:

*Refreshing Materialized Views of the Oracle Database Data Warehousing Guide.*

#### COMPILE

Specify COMPILE to explicitly revalidate a materialized view. If an object upon which the materialized view depends is dropped or altered, then the materialized view remains accessible, but it is invalid for query rewrite. You can use this clause to explicitly revalidate the materialized view to make it eligible for query rewrite.

If the materialized view fails to revalidate, then it cannot be refreshed or used for query rewrite.

#### See Also:

["Compiling a Materialized View: Example"](#)

#### CONSIDER FRESH

This clause lets you manage the staleness state of a materialized view after changes have been made to its master tables. CONSIDER FRESH directs Oracle Database to consider the materialized view fresh and therefore eligible for query rewrite in the TRUSTED or STALE\_TOLERATED modes.

#### Caution:

The CONSIDER FRESH clause also directs Oracle Database to no longer apply any rows in a materialized view log or Partition Change Tracking changes to the materialized view prior to the issuance of the CONSIDER FRESH clause. In other words, the pending changes will be ignored and deleted, not applied to the materialized view. This may result in the materialized view containing more or less data than the base table.

Because Oracle Database cannot guarantee the freshness of the materialized view, query rewrite in ENFORCED mode is not supported. This clause also sets the staleness state of the materialized view to UNKNOWN. The staleness state is displayed in the STALENESS column of the ALL\_MVIEWS, DBA\_MVIEWS, and USER\_MVIEWS data dictionary views.

A materialized view is stale if changes have been made to the contents of any of its master tables. This clause directs Oracle Database to assume that the materialized view is fresh and that no such changes have been made. Therefore, actual updates to those tables pending refresh are purged with respect to the materialized view.

### See Also:

- *Oracle Database Data Warehousing Guide* for more information on query rewrite and the implications of performing partition maintenance operations on master tables
- "[CONSIDER FRESH: Example](#)"

## Examples

### Automatic Refresh: Examples

The following statement changes the default refresh method for the sales\_by\_month\_by\_state materialized view (created in "[Creating Materialized Aggregate Views: Example](#)") to FAST:

```
ALTER MATERIALIZED VIEW sales_by_month_by_state
    REFRESH FAST;
```

The next automatic refresh of the materialized view will be a fast refresh provided it is a simple materialized view and its master table has a materialized view log that was created before the materialized view was created or last refreshed.

Because the REFRESH clause does not specify START WITH or NEXT values, Oracle Database will use the refresh intervals established by the REFRESH clause when the sales\_by\_month\_by\_state materialized view was created or last altered.

The following statement establishes a new interval between automatic refreshes for the sales\_by\_month\_by\_state materialized view:

```
ALTER MATERIALIZED VIEW sales_by_month_by_state
    REFRESH NEXT SYSDATE+7;
```

Because the REFRESH clause does not specify a START WITH value, the next automatic refresh occurs at the time established by the START WITH and NEXT values specified when the sales\_by\_month\_by\_state materialized view was created or last altered.

At the time of the next automatic refresh, Oracle Database refreshes the materialized view, evaluates the NEXT expression SYSDATE+7 to determine the next automatic refresh time, and continues to refresh the materialized view automatically once a week. Because the REFRESH clause does not explicitly specify a refresh method, Oracle Database continues to use the refresh method specified by the REFRESH clause of the CREATE MATERIALIZED VIEW or most recent ALTER MATERIALIZED VIEW statement.

### CONSIDER FRESH: Example

The following statement instructs Oracle Database that materialized view `sales_by_month_by_state` should be considered fresh. This statement allows `sales_by_month_by_state` to be eligible for query rewrite in TRUSTED mode even after you have performed partition maintenance operations on the master tables of `sales_by_month_by_state`:

```
ALTER MATERIALIZED VIEW sales_by_month_by_state CONSIDER FRESH;
```

As a result of the preceding statement, any partition maintenance operations that were done to the base table since the last refresh of the materialized view will not be applied to the materialized view. For example, the add, drop, or change of data in a partition in the base table will not be reflected in the materialized view if `CONSIDER FRESH` is used before the next refresh of the materialized view. Refer to [CONSIDER FRESH](#) for more information.

 **See Also:**

["Splitting Table Partitions: Examples"](#) for a partitioning maintenance example that would require this `ALTER MATERIALIZED VIEW` example

### Complete Refresh: Example

The following statement specifies a new refresh method, a new `NEXT` refresh time, and a new interval between automatic refreshes of the `emp_data` materialized view (created in ["Periodic Refresh of Materialized Views: Example"](#)):

```
ALTER MATERIALIZED VIEW emp_data
  REFRESH COMPLETE
  START WITH TRUNC(SYSDATE+1) + 9/24
  NEXT SYSDATE+7;
```

The `START WITH` value establishes the next automatic refresh for the materialized view to be 9:00 a.m. tomorrow. At that point, Oracle Database performs a complete refresh of the materialized view, evaluates the `NEXT` expression, and subsequently refreshes the materialized view every week.

### Enabling Query Rewrite: Example

The following statement enables query rewrite on the materialized view `emp_data` and implicitly revalidates it:

```
ALTER MATERIALIZED VIEW emp_data
  ENABLE QUERY REWRITE;
```

### Primary Key Materialized View: Example

The following statement changes the rowid materialized view `order_data` (created in ["Creating Rowid Materialized Views: Example"](#)) to a primary key materialized view. This example requires that you have already defined a materialized view log with a primary key on `order_data`.

```
ALTER MATERIALIZED VIEW order_data
  REFRESH WITH PRIMARY KEY;
```

### Compiling a Materialized View: Example

The following statement revalidates the materialized view `store_mv`:

```
ALTER MATERIALIZED VIEW order_data COMPILE;
```

#### Drop Annotation from View: Example

The following example drops annotation `Snapshot` from view `MView1`:

```
ALTER MATERIALIZED VIEW MView1 ANNOTATIONS (DROP Snapshot);
```

## ALTER MATERIALIZED VIEW LOG

### Purpose

A **materialized view log** is a table associated with the master table of a materialized view. Use the `ALTER MATERIALIZED VIEW LOG` statement to alter the storage characteristics or type of an existing materialized view log.

#### Note:

The keyword `SNAPSHOT` is supported in place of `MATERIALIZED VIEW` for backward compatibility.

#### See Also:

- [CREATE MATERIALIZED VIEW LOG](#) for information on creating a materialized view log
- [ALTER MATERIALIZED VIEW](#) for more information on materialized views, including refreshing them
- [CREATE MATERIALIZED VIEW](#) for a description of the various types of materialized views

### Prerequisites

You must be the owner of the master table, or you must have the `READ` or `SELECT` privilege on the master table and the `ALTER` privilege on the materialized view log.

#### See Also:

[Oracle Database Administrator's Guide](#) for detailed information about the prerequisites for `ALTER MATERIALIZED VIEW LOG`

## Syntax

***alter\_materialized\_view\_log ::=***

(*physical\_attributes\_clause ::=, add\_mv\_log\_column\_clause ::=, alter\_table\_partitioning ::=* (in ALTER TABLE), *parallel\_clause ::=, logging\_clause ::=, allocate\_extent\_clause ::=, shrink\_clause ::=, move\_mv\_log\_clause ::=, mv\_log\_augmentation ::=, mv\_log\_purge\_clause ::=, for\_refresh\_clause ::=*)

***physical\_attributes\_clause ::=***

***storage\_clause ::=***

***add\_mv\_log\_column\_clause ::=***

**allocate\_extent\_clause ::=**

**(size\_clause ::=)**

**shrink\_clause ::=**

**move\_mv\_log\_clause ::=**

**parallel\_clause ::=**

**mv\_log\_augmentation ::=**

(*new\_values\_clause*::=

*new\_values\_clause*::=

*mv\_log\_purge\_clause*::=

*for\_refresh\_clause*::=

## Semantics

### IF EXISTS

Specify **IF EXISTS** to alter an existing table.

Specifying **IF NOT EXISTS** with **ALTER VIEW** results in ORA-11544: Incorrect **IF EXISTS** clause for **ALTER/DROP** statement.

### FORCE

If you specify **FORCE** and any items specified with the **ADD** clause have already been specified for the materialized view log, then Oracle Database does not return an error, but silently ignores the existing elements and adds to the materialized view log any items that do not already exist in the log. Likewise, if you specify **INCLUDING NEW VALUES** and that attribute has already been specified for the materialized view log, Oracle Database ignores the redundancy and does not return an error.

### schema

Specify the schema containing the master table. If you omit *schema*, then Oracle Database assumes the materialized view log is in your own schema.

***table***

Specify the name of the master table associated with the materialized view log to be altered.

***physical\_attributes\_clause***

The *physical\_attributes\_clause* lets you change the value of the PCTFREE, PCTUSED, and INITTRANS parameters and the storage characteristics for the materialized view log, the partition, the overflow data segment, or the default characteristics of a partitioned materialized view log.

**Restriction on Materialized View Log Physical Attributes**

You cannot use the *storage\_clause* to modify extent parameters if the materialized view log resides in a locally managed tablespace. Refer to [CREATE TABLE](#) for a description of these parameters.

***add\_mv\_log\_column\_clause***

When you add a column to the master table of the materialized view log, the database does not automatically add a column to the materialized view log. Therefore, use this clause to add a column to the materialized view log. Oracle Database will encrypt the newly added column if the corresponding column of the master table is encrypted.

***alter\_table\_partitioning***

The syntax and general functioning of the partitioning clauses is the same as described for the [ALTER TABLE](#) statement. Refer to [alter\\_table\\_partitioning](#) in the documentation on [ALTER TABLE](#).

**Restrictions on Altering Materialized View Log Partitions**

Altering materialized view log partitions is subject to the following restrictions:

- You cannot use the *LOB\_storage\_clause* or *modify\_LOB\_storage\_clause* when modifying partitions of a materialized view log.
- If you attempt to drop, truncate, or exchange a materialized view log partition, then Oracle Database raises an error.

***parallel\_clause***

The *parallel\_clause* lets you specify whether parallel operations will be supported for the materialized view log.

For complete information on this clause, refer to [parallel\\_clause](#) in the documentation on [CREATE TABLE](#).

***logging\_clause***

Specify the logging attribute of the materialized view log. Refer to the [logging\\_clause](#) for a full description of this clause.

***allocate\_extent\_clause***

Use the *allocate\_extent\_clause* to explicitly allocate a new extent for the materialized view log. Refer to [allocate\\_extent\\_clause](#) for a full description of this clause.

***shrink\_clause***

Use this clause to compact the materialized view log segments. For complete information on this clause, refer to [shrink\\_clause](#) in the documentation on CREATE TABLE.

***move\_mv\_log\_clause***

Use the MOVE clause to move the materialized view log table to a different tablespace, to change other segment or storage attributes of the materialized view log, or to change the parallelism of the materialized view log.

**Restriction on Moving Materialized View Logs**

The ENCRYPT clause of the *storage\_clause* of *segment\_attributes* is not valid for materialized view logs.

**CACHE | NOCACHE Clause**

For data that will be accessed frequently, CACHE specifies that the blocks retrieved for this log are placed at the most recently used end of the LRU list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables. NOCACHE specifies that the blocks are placed at the least recently used end of the LRU list. Refer to "[CACHE | NOCACHE | CACHE READS](#)" in the documentation on CREATE TABLE for more information about this clause.

***mv\_log\_augmentation***

Use the ADD clause to augment the materialized view log so that it records the primary key values, rowid values, object ID values, or a sequence when rows in the materialized view master table are changed. This clause can also be used to record additional columns.

To stop recording any of this information, you must first drop the materialized view log and then re-create it. Dropping the materialized view log and then re-creating it forces a complete refresh for each of the existing materialized views that depend on the master table on its next refresh.

**Restriction on Augmenting Materialized View Logs**

You can specify only one PRIMARY KEY, one ROWID, one OBJECT ID, one SEQUENCE, and each column in the column list once for each materialized view log. You can specify only a single occurrence of PRIMARY KEY, ROWID, OBJECT ID, SEQUENCE, and column list within this ALTER statement. Also, if any of these values was specified at create time (either implicitly or explicitly), you cannot specify that value in this ALTER statement unless you use the FORCE option.

**OBJECT ID**

Specify OBJECT ID if you want the appropriate object identifier of all rows that are changed to be recorded in the materialized view log.

**Restriction on the OBJECT ID clause**

You can specify OBJECT ID only for logs on object tables, and you cannot specify it for storage tables.

### PRIMARY KEY

Specify PRIMARY KEY if you want the primary key values of all rows that are changed to be recorded in the materialized view log.

### ROWID

Specify ROWID if you want the rowid values of all rows that are changed to be recorded in the materialized view log.

### SEQUENCE

Specify SEQUENCE to indicate that a sequence value providing additional ordering information should be recorded in the materialized view log.

#### *column*

Specify the additional columns whose values you want to be recorded in the materialized view log for all rows that are changed. Typically these columns are filter columns (non-primary-key columns referenced by subquery materialized views) and join columns (non-primary-key columns that define a join in the WHERE clause of the subquery).

#### See Also:

- [CREATE MATERIALIZED VIEW](#) for details on explicit and implicit inclusion of materialized view log values
- *Oracle Database Administrator's Guide* for more information about filter columns and join columns
- ["Rowid Materialized View Log: Example"](#)

### NEW VALUES Clause

The NEW VALUES clause lets you specify whether Oracle Database saves both old and new values for update DML operations in the materialized view log. The value you set in this clause applies to all columns in the log, not only to columns you may have added in this ALTER MATERIALIZED VIEW LOG statement.

### INCLUDING

Specify INCLUDING to save both new and old values in the log. If this log is for a table on which you have a single-table materialized aggregate view, and if you want the materialized view to be eligible for fast refresh, then you must specify INCLUDING.

### EXCLUDING

Specify EXCLUDING to disable the recording of new values in the log. You can use this clause to avoid the overhead of recording new values.

If you have a fast-refreshable single-table materialized aggregate view defined on this table, then do not specify EXCLUDING NEW VALUES unless you first change the refresh mode of the materialized view to something other than FAST.

 See Also:

["Materialized View Log EXCLUDING NEW VALUES: Example"](#)

***mv\_log\_purge\_clause***

Use this clause alter the purge attributes of the materialized view log in the following ways:

- Change the purge from IMMEDIATE SYNCHRONOUS to IMMEDIATE ASYNCHRONOUS or from IMMEDIATE ASYNCHRONOUS to IMMEDIATE SYNCHRONOUS
- Change the purge from IMMEDIATE to scheduled or from scheduled to IMMEDIATE
- Specify a new start time and a new next time and interval

If you are altering purge from scheduled to IMMEDIATE, then the scheduled purged job associated with that materialized view log is dropped. If you are altering purge from IMMEDIATE to scheduled, then a purge job is created with the attributes provided. If you are altering scheduled purge attributes, then only those attributes specified will be changed in the scheduler purge job.

You must specify FORCE if you are altering log purge to its current state (that is, you are not making any change), unless you are changing scheduled purge attributes.

To learn whether the purge time or interval has already been set for this materialized view log, query the \*<sub>MVIEW\_LOGS</sub> data dictionary views. See the CREATE MATERIALIZED VIEW LOG clause [mv\\_log\\_purge\\_clause](#) for the full semantics of this clause.

***for\_refresh\_clause***

Use this clause to change the refresh method for which the materialized view log will be used.

**FOR SYNCHRONOUS REFRESH**

Specify this clause to change from fast refresh to synchronous refresh, or complete refresh to synchronous refresh. A staging log will be created.

If you are changing from fast refresh, then ensure that the following conditions are satisfied before using this clause:

- All changes in the materialized view log have been consumed.
- Any refresh-on-demand materialized views associated with the master table have been refreshed.
- Any refresh-on-commit materialized views associated with the master table have been converted to refresh-on-demand materialized views.

After you use this clause, you cannot perform DML operations directly on the master table. You must use the procedures in the DBMS\_SYNC\_REFRESH package to prepare and execute change data operations.

**FOR FAST REFRESH**

Specify this clause to change from synchronous refresh to fast refresh, or complete refresh to fast refresh. A materialized view log will be created.

If you are changing from synchronous refresh to fast refresh, then ensure that all changes in the staging log have been consumed before using this clause.

After you use this clause, you can perform DML operations directly on the master table.

See the CREATE MATERIALIZED VIEW LOG clause [for\\_refresh\\_clause](#) for the full semantics of this clause.

### Examples

#### Rowid Materialized View Log: Example

The following statement alters an existing primary key materialized view log to also record rowid information:

```
ALTER MATERIALIZED VIEW LOG ON order_items ADD ROWID;
```

#### Materialized View Log EXCLUDING NEW VALUES: Example

The following statement alters the materialized view log on `hr.employees` by adding a filter column and excluding new values. Any materialized aggregate views that use this log will no longer be fast refreshable. However, if fast refresh is no longer needed, this action avoids the overhead of recording new values:

```
ALTER MATERIALIZED VIEW LOG ON employees
  ADD (commission_pct)
  EXCLUDING NEW VALUES;
```

## ALTER MATERIALIZED ZONEMAP

### Purpose

Use the ALTER MATERIALIZED ZONEMAP statement to modify an existing zone map in one of the following ways:

- To change its attributes
- To change its default refresh method and mode
- To enable or disable its use for pruning
- To compile it, rebuild it, or make it unusable

#### See Also:

- [CREATE MATERIALIZED ZONEMAP](#) for information on creating zone maps
- *Oracle Database Data Warehousing Guide* for more information on zone maps

### Prerequisites

The zone map must be in your own schema or you must have the ALTER ANY MATERIALIZED VIEW system privilege.

The user who owns the schema containing the zone map must have access to any base tables of the zone map that reside outside of that schema, either through a READ or SELECT object privilege on each of the tables, or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

### Syntax

***alter\_materialized\_zonemap::=***

***alter\_zonemap\_attributes::=***

***zonemap\_refresh\_clause::=***

**Note:**

When specifying the *zonemap\_refresh\_clause*, you must specify at least one clause after the `REFRESH` keyword.

## Semantics

### IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### *schema*

Specify the schema containing the zone map. If you omit `schema`, then Oracle Database assumes the zone map is in your own schema.

### `zonemap_name`

Specify the name of the zone map to be altered.

### `alter_zonemap_attributes`

Use this clause to modify the following attributes for the zone map: `PCTFREE`, `PCTUSED`, and `CACHE` or `NOCACHE`. These attributes have the same semantics for `ALTER MATERIALIZED ZONEMAP` and `CREATE MATERIALIZED ZONEMAP`. For complete information on these attributes, refer to [PCTFREE](#), [PCTUSED](#), and [CACHE | NOCACHE](#) in the documentation on `CREATE MATERIALIZED ZONEMAP`.

### `zonemap_refresh_clause`

Use this clause to modify the default refresh method and mode for the zone map. This clause has the same semantics for `ALTER MATERIALIZED ZONEMAP` and `CREATE MATERIALIZED ZONEMAP`. For complete information on this clause, refer to [zonemap\\_refresh\\_clause](#) in the documentation on `CREATE MATERIALIZED ZONEMAP`.

### `ENABLE | DISABLE PRUNING`

Use this clause to enable or disable use of the zone map for pruning. This clause has the same semantics for `ALTER MATERIALIZED ZONEMAP` and `CREATE MATERIALIZED ZONEMAP`. For complete information on this clause, refer to [ENABLE | DISABLE PRUNING](#) in the documentation on `CREATE MATERIALIZED ZONEMAP`.

### `COMPILE`

This clause lets you explicitly compile the zone map. This operation validates the zone map after a DDL operation changes the structure of one or more of its base tables. It is usually not necessary to issue this clause because Oracle database automatically compiles a zone map that requires compilation before using it. However, if you would like to explicitly compile a zone map, then you can use this clause to do so.

The result of compiling a zone map depends on whether a base table is changed in a way that affects the zone map. For example, if a column is added to a base table, then the zone map will be valid after compilation because the change does not affect the zone map. However, if a column that is included in the defining subquery of the zone map is dropped from a base table, then the zone map will be invalid after compilation.

You can determine if a zone map requires compilation by querying the `COMPILE_STATE` column of the `ALL_`, `DBA_`, and `USER_ZONEMAPS` data dictionary views. If the value of the column is `NEEDS_COMPILE`, then the zone map requires compilation.

## REBUILD

This clause lets you explicitly rebuild the zone map. This operation refreshes the data in the zone map. This clause is useful in the following situations:

- You can use this clause to refresh the data for a refresh-on-demand zone map. Refer to the `ON DEMAND` clause in the documentation on `CREATE MATERIALIZED ZONEMAP` for more information.
- You must issue this clause after an `EXCHANGE PARTITION` operation on one of the base tables of a zone map, regardless of the default refresh mode of the zone map.
- If a zone map is marked unusable, then you must issue this clause to mark it usable. You can determine if a zone map is marked unusable by querying the `UNUSABLE` column of the `ALL_`, `DBA_`, and `USER_ZONEMAPS` data dictionary views.

## UNUSABLE

Specify this clause to make the zone map unusable. Subsequent queries will not use the zone map and the database will no longer maintain the zone map. You can make the zone map usable again by issuing an `ALTER MATERIALIZED ZONEMAP ... REBUILD` statement.

## Examples

### Modifying Zone Map Attributes: Example

The following statement modifies the `PCTFREE` and `PCTUSED` attributes of zone map `sales_zmap`, and modifies the zone map so that it does not use caching:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  PCTFREE 20 PCTUSED 50 NOCACHE;
```

### Modifying the Default Refresh Method and Mode for a Zone Map: Example

The following statement changes the default refresh method to `FAST` and the default refresh mode to `ON COMMIT` for zone map `sales_zmap`:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  REFRESH FAST ON COMMIT;
```

### Disabling Use of a Zone Map for Pruning: Example

The following statement disables use of zone map `sales_zmap` for pruning:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  DISABLE PRUNING;
```

### Compiling a Zone Map: Example

The following statement compiles zone map `sales_zmap`:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
  COMPILE;
```

### Rebuilding a Zone Map: Example

The following statement rebuilds zone map `sales_zmap`:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
    REBUILD;
```

### Making a Zone Map Unusable: Example

The following statement makes zone map `sales_zmap` unusable:

```
ALTER MATERIALIZED ZONEMAP sales_zmap
    UNUSABLE;
```

## ALTER MLE ENV

### Purpose

Use `ALTER MLE ENV` to alter an existing MLE environment. You can add, remove, and alter mappings for import names and set language options.

### Prerequisites

You must have the `ALTER ANY MLE` privilege to alter an environment in schemas other than your own. No privilege is needed to alter an environment in your own schema.

### Syntax

### Semantics

#### IF EXISTS

The `ALTER MLE MODULE` statement raises an `ORA-04103` error if the module does not exist, or an `ORA-00922` error if an invalid attribute is specified.

#### *schema*

Specify the schema containing the MLE module. If you do not specify the schema, then Oracle Database assumes that the module is in your own schema.

#### ADD IMPORTS Clause

Use `ADD IMPORTS` to add new mappings from import names to MLE module schema objects. Mappings to be added are specified as a comma-separated list enclosed in

parentheses. Each element in the list is of the form: *import-name MODULE [schema]. mle-module-name*.

The following cases produce errors:

- If the environment already contains one or more of the import names, an ORA-04109 error is thrown.
- If one or more of the MLE modules does not reside in the same schema as the environment, an ORA-01031 error is thrown.

### DROP IMPORTS Clause

Use `DROP IMPORTS` to remove import names from the environment.

If the environment does not contain one or more of the specified import names, an ORA-04110 error is thrown.

### ALTER IMPORTS Clause

Use `ALTER IMPORTS` to update import mappings for each of the specified import names.

The following cases produce errors:

- If the environment does not contain one or more of the import names, an ORA-04110 error is thrown.
- If one or more of the new MLE modules does not reside in the same schema as the environment, an ORA-01031 error is thrown.

### SET LANGUAGE OPTIONS Clause

Use `LANGUAGE OPTIONS` to specify language options for all execution contexts created with this environment. Language options are specified as a string literal consisting of comma-separated key-value pairs. Language options are only parsed at runtime when an execution context is created using the MLE environment.

If at context creation the language options string turns out to be invalid (invalid format, unsupported options), an ORA-04152 error is thrown.

#### Example

The following example modifies an existing environment `myenv` by enabling JavaScript in strict mode:

```
ALTER MLE ENV scott."myenv" SET LANGUAGE OPTIONS 'js.strict=true';
```

### COMPILE Clause

Use `COMPILE` to explicitly recompile an MLE environment. You can use this clause to revalidate an environment that has become invalid and thereby catch errors before run time.

#### See Also:

- *MLE JavaScript Modules and Environments*

- CREATE MLE ENV
- DROP MLE ENV

# ALTER MLE MODULE

## Purpose

Use `ALTER MLE MODULE` to add metadata to existing MLE modules in the database.

## Prerequisites

To alter MLE modules in another schema you need the `ALTER ANY MLE` system privilege. No privileges are required to alter MLE modules in your own schema.

## Syntax

## Semantics

### IF EXISTS

The `ALTER MLE MODULE` statement raises an `ORA-04103` error if the module does not exist, or an `ORA-00922` error if an invalid attribute is specified.

### *schema*

Specify the schema containing the MLE module. If you do not specify the schema, then Oracle Database assumes that the module is in your own schema.

### *module\_name*

*module\_name* refers to the name of the MLE module.

### CLOB

`CLOB` refers to the text you can attach to an MLE module. You can use it to refer to a commit in a version control system or as a part of a Software Bill of Materials. The `CLOB` contents are freeform metadata that can be attached to the MLE module. The metadata does not impact module functionality in any way. Oracle recommends that the metadata be used to record version information for the MLE module, e.g., the commit in a version control system that corresponds to the deployed version of the module, or a Software Bill of Materials for the module, for example the contents of `package-lock.json` for a bundled JavaScript module.

## Examples

The following example attaches metadata as `JSON` to MLE module `myMLEModule`:

```
ALTER MLE MODULE myMLEModule
SET METADATA USING CLOB (
SELECT JSON(
  '{
    "name": "value",
    "version": "1.2.0",
    "commitHash": "23fas4h",
    "projectName": "Database Backend"
  }')
)
```

 **See Also:**

- [MLE JavaScript Modules and Environments](#)
- [CREATE MLE MODULE](#)
- [DROP MLE MODULE](#)

## ALTER OPERATOR

### Purpose

Use the ALTER OPERATOR statement to add bindings to, drop bindings from, or compile an existing operator.

 **See Also:**

- [CREATE OPERATOR](#)

### Prerequisites

The operator must already have been created by a previous CREATE OPERATOR statement. The operator must be in your own schema or you must have the ALTER ANY OPERATOR system privilege. You must have the EXECUTE object privilege on the operators and functions referenced in the ALTER OPERATOR statement.

### Syntax

***alter\_operator::=***

([\*add\\_binding\\_clause::=\*](#), [\*drop\\_binding\\_clause::=\*](#))

***add\_binding\_clause ::=***

(*implementation\_clause ::=*, *using\_function\_clause ::=*)

***implementation\_clause ::=***

(*context\_clause ::=*)

***context\_clause ::=***

***using\_function\_clause ::=***

***drop\_binding\_clause ::=***

## Semantics

### IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### *schema*

Specify the schema containing the operator. If you omit this clause, then Oracle Database assumes the operator is in your own schema.

### *operator*

Specify the name of the operator to be altered.

### *add\_binding\_clause*

Use this clause to add an operator binding and specify its parameter data types and return type. The signature must be different from the signature of any existing binding for this operator.

If a binding of an operator is associated with an indextype and you add another binding to the operator, then Oracle Database does not automatically associate the new binding with the indextype. If you want to make such an association, then you must issue an explicit `ALTER INDEXTYPE ... ADD OPERATOR` statement.

### *implementation\_clause*

This clause has the same semantics in `CREATE OPERATOR` and `ALTER OPERATOR` statements. For full information, refer to [implementation\\_clause](#) in the documentation on `CREATE OPERATOR`.

### *context\_clause*

This clause has the same semantics in `CREATE OPERATOR` and `ALTER OPERATOR` statements. For full information, refer to [context\\_clause](#) in the documentation on `CREATE OPERATOR`.

### *using\_function\_clause*

This clause has the same semantics in `CREATE OPERATOR` and `ALTER OPERATOR` statements. For full information, refer to [using\\_function\\_clause](#) in the documentation on `CREATE OPERATOR`.

### *drop\_binding\_clause*

Use this clause to specify the list of parameter data types of the binding you want to drop from the operator. You must specify `FORCE` if the binding has any dependent objects, such as an indextype or an ancillary operator binding. If you specify `FORCE`, then Oracle Database marks `INVALID` all objects that are dependent on the binding. The dependent objects are revalidated the next time they are referenced in a DDL or DML statement or a query.

You cannot use this clause to drop the only binding associated with this operator. Instead you must use the `DROP OPERATOR` statement. Refer to [DROP OPERATOR](#) for more information.

## COMPILE

Specify COMPILE to cause Oracle Database to recompile the operator.

### Examples

#### Compiling a User-defined Operator: Example

The following example compiles the operator `eq_op` (which was created in "[Creating User-Defined Operators: Example](#)"):

```
ALTER OPERATOR eq_op COMPILE;
```

# ALTER OUTLINE

### Purpose

#### Note:

Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. SQL plan management creates SQL plan baselines, which offer superior SQL performance stability compared with stored outlines.

You can migrate existing stored outlines to SQL plan baselines by using the `MIGRATE_STORED_OUTLINE` function of the `DBMS_SPM` package or Enterprise Manager Cloud Control. When the migration is complete, the stored outlines are marked as migrated and can be removed. You can drop all migrated stored outlines on your system by using the `DROP_MIGRATED_STORED_OUTLINE` function of the `DBMS_SPM` package.

See Also: *Oracle Database SQL Tuning Guide* for more information about SQL plan management and *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_SPM` package

Use the `ALTER OUTLINE` statement to rename a stored outline, reassign it to a different category, or regenerate it by compiling the outline's SQL statement and replacing the old outline data with the outline created under current conditions.

#### See Also:

[CREATE OUTLINE](#) for information on creating an outline

### Prerequisites

To modify an outline, you must have the `ALTER ANY OUTLINE` system privilege.

## Syntax

***alter\_outline ::=***

## Semantics

### PUBLIC | PRIVATE

Specify PUBLIC if you want to modify the public version of this outline. This is the default.

Specify PRIVATE if you want to modify an outline that is private to the current session and whose data is stored in the current parsing schema.

### *outline*

Specify the name of the outline to be modified.

### REBUILD

Specify REBUILD to regenerate the execution plan for *outline* using current conditions.

#### See Also:

["Rebuilding an Outline: Example"](#)

### RENAME TO Clause

Use the RENAME TO clause to specify an outline name to replace *outline*.

### CHANGE CATEGORY TO Clause

Use the CHANGE CATEGORY TO clause to specify the name of the category into which the *outline* will be moved.

### ENABLE | DISABLE

Use this clause to selectively enable or disable this outline. Outlines are enabled by default. The DISABLE keyword lets you disable one outline without affecting the use of other outlines.

## Examples

### [Rebuilding an Outline: Example](#)

The following statement regenerates a stored outline called `salaries` by compiling the text of the outline and replacing the old outline data with the outline created under current conditions.

```
ALTER OUTLINE salaries REBUILD;
```

## ALTER PACKAGE

### Purpose

Packages are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `ALTER PACKAGE` statement to explicitly recompile a package specification, body, or both. Explicit recompilation eliminates the need for implicit run-time recompilation and prevents associated run-time compilation errors and performance overhead.

Because all objects in a package are stored as a unit, the `ALTER PACKAGE` statement recompiles all package objects together. You cannot use the `ALTER PROCEDURE` statement or `ALTER FUNCTION` statement to recompile individually a procedure or function that is part of a package.

#### Note:

This statement does not change the declaration or definition of an existing package. To redeclare or redefine a package, use the `CREATE PACKAGE` or the `CREATE PACKAGE BODY` statement with the `OR REPLACE` clause.

### Prerequisites

For you to modify a package, the package must be in your own schema or you must have `ALTER ANY PROCEDURE` system privilege.

### Syntax

`alter_package ::=`

(`package_compile_clause`: See *Oracle Database PL/SQL Language Reference* for the syntax of this clause.)

### Semantics

#### IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying IF NOT EXISTS with ALTER VIEW results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

#### ***schema***

Specify the schema containing the package. If you omit *schema*, then Oracle Database assumes the package is in your own schema.

#### ***package\_name***

Specify the name of the package to be recompiled.

#### ***package\_compile\_clause***

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling packages.

#### **EDITIONABLE | NONEDITIONABLE**

Use these clauses to specify whether the package becomes an editioned or noneditioned object if editioning is later enabled for the schema object type PACKAGE in *schema*. The default is EDITIONABLE. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

## ALTER PLUGGABLE DATABASE

### Purpose

Use the ALTER PLUGGABLE DATABASE statement to modify a pluggable database (PDB). The PDB can be a traditional PDB, an application container, or an application PDB.

This statement enables you to perform the following tasks:

- Unplug a PDB from a multitenant container database (CDB) (using the *pdb\_unplug\_clause*)
- Modify the settings of a PDB (using the *pdb\_settings\_clauses*)
- Bring PDB data files online or take them offline (using the *pdb\_datafile\_clause*)
- Back up and recover a PDB (using the *pdb\_recovery\_clauses*)
- Modify the state of a PDB (using the *pdb\_change\_state\_clause*)
- Modify the state of multiple PDBs within a CDB (using the *pdb\_change\_state\_from\_root\_clause*)
- Perform operations on applications in an application container (using the *application\_clauses*)
- Create and manage PDB snapshots using the *snapshot\_clauses*

 **Note:**

You can perform all ALTER PLUGGABLE DATABASE tasks by connecting to a PDB and running the corresponding ALTER DATABASE statement. This functionality is provided to maintain backward compatibility for applications that have been migrated to a CDB environment. The exception is modifying PDB storage limits, for which you must use the *pdb\_storage\_clause* of ALTER PLUGGABLE DATABASE.

 **See Also:**

[CREATE PLUGGABLE DATABASE](#) for information on creating PDBs

### Prerequisites

You must be connected to a CDB.

To specify the *pdb\_unplug\_clause*, the current container must be the root or the application root, you must be authenticated AS SYSDBA or AS SYSOPER, and the SYSDBA or SYSOPER privilege must be either granted to you commonly, or granted to you locally in the root and locally in the PDB you want to unplug.

To specify the *pdb\_settings\_clauses*, the current container must be the PDB whose settings you want to modify and you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the PDB. To specify the *pdb\_logging\_clauses* or the RENAME GLOBAL\_NAME clause, you must also have the RESTRICTED SESSION privilege, either granted commonly or granted locally in the PDB being renamed, and the PDB must be in READ WRITE RESTRICTED mode.

To specify the *pdb\_datafile\_clause*, the current container must be the PDB whose datafiles you want to bring online or take offline and you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the PDB.

To specify the *pdb\_recovery\_clauses*, the current container must be the PDB you want to back up or recover and you must have the ALTER DATABASE privilege, either granted commonly or granted locally in the PDB.

To specify the *pdb\_change\_state* clause, the current container must be the PDB whose state you want to change and you must be authenticated AS SYSBACKUP, AS SYSDBA, AS SYSDG, or AS SYSOPER.

To specify the *pdb\_change\_state\_from\_root* clause, the current container must be the root or the application root, you must be authenticated AS SYSBACKUP, AS SYSDBA, AS SYSDG, or AS SYSOPER, and the SYSBACKUP, SYSDBA, SYSDG, or SYSOPER privilege must be either granted to you commonly, or granted to you locally in the root or application root, and locally in the PDB(s) whose state(s) you want to change.

To specify the *application\_clauses*, the current container must be an application container, you must be authenticated AS SYSBACKUP or AS SYSDBA, and the SYSBACKUP or SYSDBA privilege must be either granted to you commonly, or granted to you locally

in the application root and locally in the application PDB(s) in which you want to perform application operations.

### Syntax

***alter\_pluggable\_database ::=***

(*pdb\_unplug\_clause ::=, pdb\_settings\_clauses ::=, pdb\_datafile\_clause ::=,  
pdb\_recovery\_clauses, pdb\_change\_state ::=, pdb\_change\_state\_from\_root ::=,  
application\_clauses ::=*)

***database\_clause ::=***

***pdb\_unplug\_clause ::=***

***pdb\_unplug\_encrypt ::=***

*create\_snapshot\_clause ::=*

*drop\_snapshot\_clause ::=*

*set\_max\_pdb\_snapshots ::=*

*prepare\_clause ::=*

*drop\_mirror\_copy ::=*

*lost\_write\_protection ::=*

The usage for the `lost_write_protection` clause with the `ALTER PLUGGABLE DATABASE` statement is identical to the `ALTER DATABASE` statement. Look here [ALTER DATABASE](#) for syntax details.

***pdb\_managed\_recovery ::=***

### Semantics

#### ***database\_clause***

Specify the `PLUGGABLE DATABASE` option for a container database.

#### ***pdb\_name***

Specify the name of the database to be altered. If you omit `db_name`, then Oracle Database alters the database identified by the value of the initialization parameter `DB_NAME`. You can alter only the database whose control files are specified by the initialization parameter `CONTROL_FILES`. The database identifier is not related to the Oracle Net database specification.

#### ***pdb\_unplug\_clause***

This clause lets you unplug a PDB from a CDB. When you unplug a PDB, Oracle stores information about the PDB in a file on your operating system. You can subsequently use this file to plug the PDB into a CDB.

For `pdb_name`, specify the name of the PDB you want to unplug. The PDB must be closed—that is, the open mode must be `MOUNTED`. In an Oracle Real Application Clusters (Oracle RAC) environment, the PDB must be closed in all Oracle RAC instances

For `filename`, specify the full path name of the operating system file in which to store information about the PDB. The file name that you specify determines the type of information stored and how it is stored.

- If you specify a file name that ends with the extension `.xml`, then Oracle creates an XML file containing metadata about the PDB. You can then copy the XML file and the PDB's data files to a new location and specify the XML file name when plugging the PDB into a CDB. In this case, you must copy the PDB's data files separately.
- If you specify a file name that ends with the extension `.pdb`, then Oracle creates a `.pdb` archive file. This is a compressed file that includes an XML file containing metadata about the PDB, as well as the PDB's data files. You can then copy this single archive file to a new location and specify the archive file name when plugging the PDB into a CDB. This eliminates having to copy the PDB's data files separately. When you use a `.pdb` archive file when plugging in a PDB, this file is extracted when you plug in the PDB, and the PDB's files are placed in the same directory as the `.pdb` archive file.

After a PDB is unplugged, it remains in the CDB with an open mode of `MOUNTED` and a status of `UNPLUGGED`. The only operation you can perform on an unplugged PDB is `DROP PLUGGABLE DATABASE`, which will remove it from the CDB. You must drop the PDB before you can plug it into the same CDB or another CDB.

 **See Also:**

- *Oracle Database Administrator's Guide* for more information on unplugging a PDB
- The [create\\_pdb\\_from\\_xml](#) clause of CREATE PLUGGABLE DATABASE for information on plugging a PDB into a CDB

### ***pdb\_unplug\_encrypt***

You must have the SYSKM privilege to execute this command.

#### **United PDBs**

- ENCRYPT USING transport\_secret is optional.
- If TDE is in use, you must specify this clause. If TDE is not in use, the statement throws the following error ORA-46680:master keys of the container database must be exported.
- The wallet must be open in ROOT if TDE is in use.
- Keys are encrypted using the provided transport secret and exported into the .XML or archive file

#### **Unplugging a PDB Into an XML Metadata File: Example**

```
ALTER PLUGGABLE DATABASE CDB1_PDB2 UNPLUG INTO '/tmp/cdb1_pdb2.xml' ENCRYPT  
USING transport_secret
```

#### **Unplugging a PDB Into an Archive File: Example**

```
ALTER PLUGGABLE DATABASE CDB1_PDB1_1 UNPLUG INTO '/tmp/CDB1_PDB1_1.pdb' ENCRYPT  
USING transport_secret
```

For PDBs in **isolated** mode, you need not specify ENCRYPT USING transport\_secret. This is not required because the wallet file of the PDB is copied during the creation of the pluggable database from an XML file. If you are unplugging a PDB as an archive file, the wallet file of the PDB is added to the zipped archive with the .pdb extension.

If the ewallet.p12 file already exists at the destination, a backup is automatically initiated. The backup file has the following format:

ewallet\_PLGDB\_2017090517455564.p12.

### ***pdb\_settings\_clauses***

These clauses lets you modify various settings for a PDB.

#### ***pdb\_name***

You can optionally use *pdb\_name* to specify the name of the PDB whose settings you want to modify.

#### DEFAULT EDITION Clause

Use this clause to designate the specified edition as the default edition for the PDB. For the full semantics of this clause, refer to "[DEFAULT EDITION Clause](#)" in the `ALTER DATABASE` documentation.

#### SET DEFAULT TABLESPACE Clause

Use this clause to specify or change the default type of tablespaces subsequently created in the PDB. For the full semantics of this clause, refer to "[SET DEFAULT TABLESPACE Clause](#)" in the `ALTER DATABASE` documentation.

#### DEFAULT TABLESPACE Clause

Use this clause to establish or change the default permanent tablespace of the PDB. For the full semantics of this clause, refer to "[DEFAULT TABLESPACE Clause](#)" in the `ALTER DATABASE` documentation.

#### DEFAULT TEMPORARY TABLESPACE Clause

Use this clause to change the default temporary tablespace of the PDB to a new tablespace or tablespace group. For the full semantics of this clause, refer to "[DEFAULT \[LOCAL\] TEMPORARY TABLESPACE Clause](#)" in the `ALTER DATABASE` documentation.

#### RENAME GLOBAL\_NAME TO Clause

Use this clause to change the global name of the PDB. The new global name must be unique within the CDB. For an Oracle Real Application Clusters (Oracle RAC) database, the PDB must be open in `READ WRITE RESTRICTED` mode on the current instance only. The PDB must be closed on all other instances. For the full semantics of this clause, refer to "[RENAME GLOBAL\\_NAME Clause](#)" in the `ALTER DATABASE` documentation.

 **Note:**

When you change the global name of a PDB, be sure to change the `PLUGGABLE DATABASE` property for database services that are used to connect to the PDB.

#### `set_time_zone_clause`

Use this clause to modify the time zone setting for the PDB. For the full semantics of this clause, refer to [`set\_time\_zone\_clause`](#) in the `ALTER DATABASE` documentation.

#### `database_file_clauses`

Use this clause to modify data files and temp files for the PDB. For the full semantics of this clause, refer to [`database\_file\_clauses`](#) in the `ALTER DATABASE` documentation.

#### `supplemental_db_logging`

Use these clauses to instruct Oracle Database to add or stop adding supplemental data into the log stream for the PDB.

- Specify the `ADD SUPPLEMENTAL LOG` clause to add supplemental data into the log stream for the PDB. In order to issue this clause, supplemental logging must have been enabled

for the CDB root with the `ALTER DATABASE ... ADD SUPPLEMENTAL LOG ...` statement. The level of supplemental logging that you specify for the PDB does not need to match that of the CDB root. That is, you can specify any of the clauses `DATA`, `supplemental_id_key_clause`, or `supplemental_plsql_clause` for the PDB, regardless of which clause was specified when enabling supplemental logging for the CDB root.

- Specify the `DROP SUPPLEMENTAL LOG` clause to stop adding supplemental data into the log stream for the PDB.

**ADD SUPPLEMENTAL LOG DATA SUBSET DATABASE REPLICATION**, of `ALTER PLUGGABLE DATABASE` enables low impact minimal supplemental logging on the PDB.

- You can only execute this DDL on a pluggable database.
- You can execute this DDL only when the `enable_goldengate_replication` parameter is TRUE, and database compatible is 19.0 or higher.
- You must enable minimal supplemental logging in `CDB$ROOT` to run this command.
- After you execute this DDL, minimal supplemental logging will become low impact for the pluggable database. `SYS.PROPS` will be updated to indicate that low impact minimal supplemental logging is enabled at the PDB level for this pluggable database.

**DROP SUPPLEMENTAL LOG DATA SUBSET DATABASE REPLICATION**, of `ALTER PLUGGABLE DATABASE` disables low impact minimal supplemental logging on the PDB.

- You can only execute this DDL on a pluggable database.
- You can execute this DDL only when the `enable_goldengate_replication` parameter is TRUE, and database compatible is 19.0 or higher.
- You must enable minimal supplemental logging in `CDB$ROOT` to run this command.
- `SYS.PROPS` will be updated to indicate that supplemental logging for subset database replication is disabled at the PDB level for this pluggable database. If supplemental logging for subset database replication is also disabled at `CDB$ROOT` (CDB level), then low impact minimal supplemental logging will be disabled for this pluggable database.

For the full semantics of this clause, refer to [supplemental\\_db\\_logging](#) in the `ALTER DATABASE` documentation.

#### *pdb\_storage\_clause*

Use this clause to modify the storage limits for a PDB.

This clause has the same semantics as the [\*pdb\\_storage\\_clause\*](#) in the `CREATE PLUGGABLE DATABASE` documentation, with the following additions:

- If you specify `MAXSIZE size_clause`, then the value you specify for `size_clause` must be greater than or equal to the combined size of the existing tablespaces belonging to the PDB. Otherwise, an error occurs.
- If you specify `MAX_AUDIT_SIZE size_clause`, then the value you specify for `size_clause` must be greater than or equal to the amount of storage used by the existing unified audit OS spillover (.bin format) files in the PDB. Otherwise, an error occurs.

- If you specify `MAX_DIAG_SIZE size_clause`, then the value you specify for `size_clause` must be greater than or equal to the amount of storage for diagnostics in the Automatic Diagnostic Repository (ADR) that is currently used by the PDB. Otherwise an error occurs.

### ***pdb\_logging\_clauses***

Use these clauses to set or change the logging characteristics of the PDB.

#### ***logging\_clause***

Use this clause to change the default logging attribute for tablespaces subsequently created within the PDB. This clause has the same semantics as the [logging\\_clause](#) in the `CREATE PLUGGABLE DATABASE` documentation.

#### ***pdb\_force\_logging\_clause***

Use this clause to place a PDB into, or take it out of, one of four logging modes.

Force logging mode instructs the database to log all changes in the PDB, except changes in temporary tablespaces and temporary segments. Force nologging mode instructs the database to not log any changes in the PDB.

Standby nologging instructs the database to not log operations that qualify to be done without logging. The database sends the data blocks that were created by the operation to each qualifying standby database in the Data Guard configuration, typically resulting in those standbys not having invalid blocks.

CDB-wide force logging mode takes precedence over any other setting. PDB-level force logging mode and force nologging mode take precedence over and are independent of any `LOGGING`, `NOLOGGING`, or `FORCE LOGGING` settings you specify for individual tablespaces in the PDB and any `LOGGING` or `NOLOGGING` settings you specify for individual database objects in the PDB.

- Specify `ENABLE FORCE LOGGING` to place the PDB in force logging mode. If the PDB is currently in force nologging mode, then specifying this clause results in an error. You must first specify `DISABLE FORCE NOLOGGING`.
- Specify `DISABLE FORCE LOGGING` to take the PDB out of force logging mode. If the PDB is not currently in force logging mode, then specifying this clause results in an error.
- Specify `ENABLE FORCE NOLOGGING` to place the PDB in force nologging mode. If the PDB is currently in force logging mode, then specifying this clause results in an error. You must first specify `DISABLE FORCE LOGGING`. The nonlogged operations will use classic invalidation redo, even if the CDB has a standby nologging mode set.
- Specify `DISABLE FORCE NOLOGGING` to take the PDB out of force nologging mode. If the PDB is not currently in force nologging mode, then specifying this clause results in an error.
- Specify `SET STANDBY NOLOGGING FOR LOAD PERFORMANCE` to put the PDB into standby nologging for load performance mode. In this mode the data loaded as part of the nonlogged task is sent to the qualifying standbys via a private network connection, provided that doing so will not slow down the load process. If a slow down occurs, then the data is not sent but fetched automatically from the primary as each standby encounters the invalidation redo and will be retried until the data blocks are eventually received.

- Specify SET STANDBY NOLOGGING FOR DATA AVAILABILITY to put the PDB into standby nologging for data availability mode. In this mode the data loaded as part of the nonlogged task is sent to the qualifying standbys either via a network connection to them, or if that fails, via block images in the redo. That is to say, in this mode the load will switch to be done in a logged fashion if the network connection or related processes prevent the sending of the data over the private network connection.

For the standby nologging modes a qualifying standby is one that is open for read, running managed recovery, and receiving redo into standby redo logs.

This clause does not change the default LOGGING or NOLOGGING mode of the PDB specified by the [logging\\_clause](#).

#### ***pdb\_refresh\_mode\_clause***

Use this clause to change the refresh mode of a PDB. You can specify this clause only for a refreshable PDB, that is, a PDB whose current refresh mode is MANUAL or EVERY *refresh\_interval* MINUTES or HOURS. You can switch a PDB from manual refresh to automatic refresh, or from automatic refresh to manual refresh. You can also use this clause to change the number of minutes between automatic refreshes. You can switch a PDB from manual or automatic refresh to no refresh, but you cannot enable manual or automatic refresh for a PDB that is not refreshable. For the complete semantics of this clause, refer to the [pdb\\_refresh\\_mode\\_clause](#) in the documentation on CREATE PLUGGABLE DATABASE.

#### **REFRESH**

Specify this clause to perform a manual refresh of a refreshable PDB, that is, a PDB whose current refresh mode is MANUAL or EVERY *number* MINUTES. The PDB must be closed. For more information on refreshable PDBs, refer to the [pdb\\_refresh\\_mode\\_clause](#) in the documentation on CREATE PLUGGABLE DATABASE.

#### ***pdb\_refresh\_switchover\_clause***

Use this clause to reverse roles between a refreshable clone PDB and a primary PDB. This clause makes the refreshable clone PDB into a primary PDB, which can be opened in read write mode. The former primary PDB becomes the refreshable clone..

- This command must be executed from the primary PDB .
- REFRESH MODE NONE may not be specified when issuing this statement.
- The *dblink* should point to the Root of the CDB where the refreshable clone PDB currently resides.
- After this operation, the current PDB will become the refreshable clone and can only be opened in READ ONLY mode.
- The database link user must exist in the primary PDB, if the refreshable clone exists in a different CDB.

#### **PRIORITY**

You can control the order of operations on PDBs by assigning a PRIORITY to the PDB. The priority *value* should be a whole number greater than 0 and less than 4099. A value outside this range throws an error.

The following ordering rules apply to manage different kinds of PDBs:

- PDBs are processed in an ascending order of priority. A PDB with a lower priority value will be processed before a PDB with a higher priority value.
- PDBs with the same priority may be processed in any order. However, if App PDBs and the App Root have the same priority or have no priority, App PDBs will still be opened after the App Root.
- PDBs have no priority are considered to be the lowest priority.
- PDB priority for a given PDB is applicable to all RAC instances, i.e priority is NOT specific to a given RAC instance.
- Priority will not be copied from source PDB to target PDB by plug, unplug or refreshable clone.
- App PDBs cannot have a higher priority than App Root.
- App Root clones have the same priority as App Roots, and cannot be explicitly given a PDB priority.
- The priority of `CDB$ROOT` and `PDB$SEED` is determined internally by Oracle RDBMS and is not subject to PDB priority .

### SET CONTAINER\_MAP

Use this clause to specify the `CONTAINER_MAP` database property for an application container. The current container must be the application root. The `map_object` is of the form `[schema.]table`. For `schema`, specify the schema containing `table`. If you omit `schema`, then the database assumed that the table is in your own schema. For `table`, specify a range-, list-, or hash-partitioned table.

### CONTAINERS DEFAULT TARGET

Use this clause to specify the default container for DML statements in an application container. You must be connect to the application root.

- For `container_name`, specify the name of the default container. The default container can be any container in the application container, including the application root or an application PDB. You can specify only one default container.
- If you specify `NONE`, then the default container is the CDB root. This is the default.

When a DML statement is issued in the application root without specifying containers in the `WHERE` clause, the DML statement affects the default container for the application container.

### CONTAINERS HOST and PORT

Use the `HOST` and `PORT` clauses if you want to create a PDB that you plan to reference from a proxy PDB. This type of PDB is called a referenced PDB.

The following statements can be executed within a PDB:

```
ALTER PLUGGABLE DATABASE CONTAINERS HOST='myhost.example.com';
```

```
ALTER PLUGGABLE DATABASE CONTAINERS PORT=1599;
```

The following statements can be executed within CDB Root, Application Root, or within a PDB :

```
ALTER PLUGGABLE DATABASE <pdbname> CONTAINERS HOST='myhost.example.com';
```

```
ALTER PLUGGABLE DATABASE <pdbname> CONTAINERS PORT=1599;
```

*pdbname* must meet the following criteria:

- If the statement is executed in Application Root, then *pdbname* has to match the name of Application Root or the name of one of its Application PDBs.
- If the statement is executed in CDB Root, then *pdbname* has to match the name of one of the PDBs in the CDB.
- If the statement is executed in a PDB, then *pdbname* has to match the name of the current PDB.

 **See Also:**

[HOST and PORT](#) of CREATE PLUGGABLE DATABASE for the full semantics of HOST and PORT

#### ***pdb\_datafile\_clause***

This clause lets you bring data files associated with a PDB online or take them offline. The PDB must be closed when you issue this clause.

- For *pdb\_name*, specify the name of the PDB. If the current container is the PDB, then you can omit *pdb\_name*.
- The DATAFILE clauses let you specify the data files you want to bring online or take offline. Use *filename* or *filenumber* to identify specific data files by name or by number. You can view data file names and numbers by querying the NAME and FILE# columns of the V\$DATAFILE dynamic performance view. Use ALL to specify all datafiles associated with the PDB.
- Specify ONLINE to bring the data files online or OFFLINE to take the data files offline.

#### ***pdb\_recovery\_clauses***

Use the *pdb\_recovery\_clauses* to back up and recover a PDB.

#### ***pdb\_name***

You can optionally use *pdb\_name* to specify the name of the PDB you want to back up or recover.

#### ***pdb\_general\_recovery***

This clause lets you control media recovery for the PDB or standby database or for specified tablespaces or files. The *pdb\_general\_recovery* clause has the same semantics as the *general\_recovery* clause of ALTER DATABASE. Refer to the [general\\_recovery](#) clause of ALTER DATABASE for more information.

#### **BACKUP Clauses**

Use these clauses to move all of the data files in the PDB into or out of online backup mode (also called hot backup mode). These clauses have the same semantics in ALTER PLUGGABLE DATABASE and ALTER DATABASE. Refer to the "BACKUP Clauses" of ALTER DATABASE for more information.

#### **RECOVERY Clauses**

Use these clauses to enable or disable a PDB for recovery. The PDB must be closed—that is, the open mode must be MOUNTED.

- Specify `ENABLE RECOVERY` to bring all data files that belong to a PDB online and enable the PDB for recovery.
- Specify `DISABLE RECOVERY` to take all data files that belong to a PDB offline and disable the PDB for recovery.

 **See Also:**

*Oracle Data Guard Concepts and Administration* for more information on the RECOVERY clauses

#### ***pdb\_change\_state***

This clause enables you to change the state, or open mode, of a PDB. [Table 11-2](#) lists the open modes of a PDB.

- Specify the `pdb_open` clause to change the open mode to READ WRITE, READ ONLY, or MIGRATE.
- Specify the `pdb_close` clause to change the open mode to MOUNTED.

**Table 11-2 PDB Open Modes**

Open Mode	Description
READ WRITE	A PDB in open read/write mode allows queries and user transactions to proceed and allows users to generate redo logs.
READ ONLY	A PDB in open read-only mode allows queries but does not allow user changes.
MIGRATE	When a PDB is in open migrate mode, you can run database upgrade scripts on the PDB.
MOUNTED	When a PDB is in mounted mode, it behaves like a non-CDB in mounted mode. It does not allow changes to any objects, and it is accessible only to database administrators. It cannot read from or write to data files. Information about the PDB is removed from memory caches. Cold backups of the PDB are possible.

You can view the open mode of a PDB by querying the `OPEN_MODE` column of the `V$PDBS` view.

 **See Also:**

*Oracle Database Administrator's Guide* for a complete description of PDB open modes

#### ***pdb\_name***

You can optionally use `pdb_name` to specify the name of the PDB whose open mode you want to change.

### ***pdb\_open***

This clause lets you change the open mode of a PDB to READ WRITE, READ ONLY, or MIGRATE. When you specify this clause, the PDB must be in MOUNTED mode unless you specify the FORCE keyword.

If you do not specify READ WRITE or READ ONLY, then the default is READ WRITE. The exception is when the PDB belongs to a CDB that is used as a physical standby database, in which case the default is READ ONLY.

#### **READ WRITE**

Specify this clause to change the open mode to READ WRITE.

#### **READ ONLY**

Specify this clause to change the open mode to READ ONLY.

#### **HYBRID READ ONLY**

Specify this clause to open a PDB in READ ONLY and READ WRITE mode depending on the type of user that connects to it. When a local user connects to the PDB, the PDB operates in READ ONLY mode. The PDB operates in READ WRITE mode for common users.

#### **[READ WRITE] UPGRADE**

Specify this clause to change the open mode to MIGRATE. The READ WRITE keywords are optional and are provided for semantic clarity.

#### **RESTRICTED**

If you specify the optional RESTRICTED keyword, then the PDB is accessible only to users with the RESTRICTED SESSION privilege in the PDB.

If the PDB is in READ WRITE or READ ONLY mode, and you specify the RESTRICTED and FORCE keywords while changing the open mode, then all sessions connected to the PDB that do not have the RESTRICTED SESSION privilege in the PDB are terminated, and their transactions are rolled back.

#### **FORCE**

Specify this keyword to change the open mode of a PDB from READ WRITE to READ ONLY, or from READ ONLY to READ WRITE. The FORCE keyword allows users to remain connected to the PDB while the open mode is changed.

When you specify FORCE to change the open mode of a PDB from READ WRITE to READ ONLY, any READ WRITE transaction that is open when you change the open mode will not be allowed to perform any more DML operations or to COMMIT.

#### **Restriction on FORCE**

You cannot specify the FORCE keyword if the PDB is currently in MIGRATE mode, and you cannot specify the FORCE keyword to change a currently open PDB to MIGRATE mode.

#### **RESETLOGS**

Specify this clause to create a new PDB incarnation and open the PDB in READ WRITE mode after point-in-time recovery of the PDB.

 **See Also:**

*Oracle Database Backup and Recovery User's Guide* for more information on performing point-in-time recovery of CDBs and PDBs

#### ***instances\_clause***

In an Oracle Real Application Clusters environment, use this clause to modify the state of the PDB in the specified Oracle RAC instances. If you omit this clause, then the state of the PDB is modified only in the current instance.

- Use *instance\_name* to specify one or more instance names, in a comma-separated list enclosed in parenthesis. This modifies the state of the PDB only in those instances.
- Specify **ALL** to modify the state of the PDB in all instances.
- Specify **ALL EXCEPT** to modify the state of the PDB in all instances except the specified instances.

If the PDB is already open in one or more instances, then you can open it in additional instances, but it must be opened in the same mode as in the instances in which it is already open.

#### ***services\_clause***

- Use *service\_name* to specify one or more services, in a comma-separated list enclosed in parenthesis.
- Specify **ALL** to specify all services on the PDB.
- Specify **ALL EXCEPT** to specify all services except the services specified.

#### ***pdb\_close***

This clause lets you change the open mode of a PDB to **MOUNTED**. When you specify this clause, the PDB must be in **READ WRITE**, **READ ONLY**, or **MIGRATE** mode. This clause is the PDB equivalent of the SQL\*Plus **SHUTDOWN** command.

#### **IMMEDIATE**

If you specify the optional **IMMEDIATE** keyword, then this clause is the PDB equivalent of the SQL\*Plus **SHUTDOWN** command with the immediate mode. Otherwise, the PDB is shut down with the normal mode.

 **See Also:**

*SQL\*Plus User's Guide and Reference* for more information on the SQL\*Plus **SHUTDOWN** command

#### **ABORT**

Specify **ABORT** to forcibly shut down the PDB.

#### ***instances\_clause***

In an Oracle Real Application Clusters environment, use this clause to modify the state of the PDB in the specified Oracle RAC instances. You can close a PDB in some instances and leave it open in others. Refer to the [instances\\_clause](#) for the full semantics of this clause.

#### ***relocate\_clause***

In an Oracle Real Application Clusters environment, use this clause to instruct the database to reopen the PDB on a different Oracle RAC instance.

- Specify `RELOCATE` to reopen the PDB on a different instance that is selected by Oracle Database.
- Specify `RELOCATE TO 'instance_name'` to reopen the PDB in the specified instance.
- Specify `NORELOCATE` to close the PDB in the current instance. This is the default.

#### ***pdb\_save\_or\_discard\_state***

Use this clause to instruct the database to save or discard the open mode of the PDB when the CDB restarts.

- If you specify `SAVE`, then the PDB's open mode after the CDB restarts will be identical to its open mode just before the CDB restarted.
- If you specify `DISCARD`, then the PDB's open mode after the CDB restarts will be `MOUNTED`. This is the default.

#### ***instances\_clause***

In an Oracle Real Application Clusters environment, use this clause to instruct the database to save or discard the open mode of the PDB in the specified Oracle RAC instances. If you omit this clause, then the database applies the `SAVE` or `DISCARD` setting only to the PDB in the current instance.

- Use `instance_name` to specify one or more instance names, in a comma-separated list enclosed in parenthesis. This applies the `SAVE` or `DISCARD` setting to the PDB only in those instances.
- Specify `ALL` to apply the `SAVE` or `DISCARD` setting to the PDB in all instances.
- Specify `ALL EXCEPT` to apply the `SAVE` or `DISCARD` setting to the PDB in all instances except the specified instances.

#### ***pdb\_change\_state\_from\_root***

This clause enables you to modify the state of one or more PDBs.

- Specify the `pdb_name` for one or more PDBs whose state you want to modify.
- Specify `ALL` to modify the state of all PDBs in the CDB.
- Specify `ALL EXCEPT` to modify the state of all PDBs in the CDB except those specified by using `pdb_name`.

If a PDB is already in the specified state, then the PDB's state is unchanged and no error is returned. If the state of a PDB cannot be changed, then an error occurs only for that PDB.

### ***application\_clauses***

Use the `APPLICATION` clauses to:

- Install, patch, upgrade, and uninstall applications
- Register application versions and patch numbers
- Sync operations on applications

 **See Also:**

*Oracle Database Administrator's Guide* for more information on administering application containers

### **Specifying Application Names**

Most of the `application_clauses` require you to specify an application name. The maximum length of an application name is 30 bytes. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)". The application name must be unique within an application container.

### **Specifying Application Versions**

Several of the `application_clauses` require you to specify an application version. The application version can be up to 30 bytes in length and can contain alphanumeric characters, punctuations marks, and spaces. The application version is case-sensitive and must be enclosed in single quotation marks.

### **Specifying Comments**

Several of the `application_clauses` allow you to specify a comment to associate with an application install, patch, or upgrade operation. For `comment`, enter a character string enclosed in single quotation marks.

### **INSTALL Clauses**

Use the `INSTALL` clauses when installing an application in an application container. The current container must be the application root, not an application PDB.

- Specify the `BEGIN INSTALL` clause before you start installing the application.
  - Use `app_name` to assign a name to the application.
  - Use `app_version` to assign a version to the application.
  - The optional `COMMENT` clause allows you to enter a comment to be associated with the application version created by this installation.
- Specify the `END INSTALL` clause after you have finished installing the application.
  - You must specify the same `app_name` that you specified for the corresponding `BEGIN INSTALL` clause.
  - You need not specify `app_version`, but if you do, then you must specify the same version that you specified for the corresponding `BEGIN INSTALL` clause.

### **PATCH Clauses**

Use the PATCH clauses when patching an application in an application container. The current container must be the application root, not an application PDB.

- Specify the BEGIN PATCH clause before you start patching the application.
  - For *app\_name*, specify the name of the application you want to patch.
  - For *number*, specify the patch number.
  - The optional MINIMUM VERSION clause allows you to specify the minimum version at which the application must be before the patch can be applied. For *app\_version*, specify the minimum application version. If the current application version is lower than the minimum application version, then an error occurs. If you omit this clause, then the minimum version is the current application version.
  - The optional COMMENT clause allows you to enter a comment to be associated with the patch.
- Specify the END PATCH clause after you finish patching the application.
  - You must specify the same *app\_name* that you specified for the corresponding BEGIN PATCH clause.
  - You need not specify *number*, but if you do, then you must specify the same value that you specified for the corresponding BEGIN PATCH clause.

### UPGRADE Clauses

Use the UPGRADE clauses when upgrading an application in an application container. The current container must be the application root, not an application PDB.

If the application root is using TDE, then you must configure an external store before upgrading the application.

- Specify the BEGIN UPGRADE clause before you start upgrading the application.
  - For *app\_name*, specify the name of the application you want to upgrade.
  - For *start\_app\_version*, specify the version from which you are upgrading the application. If this version does not match the current application version, then an error occurs.
  - For *end\_app\_version*, specify the version to which you are upgrading the application.
  - The optional COMMENT clause allows you to enter a comment to be associated with the upgrade.
- Specify the END UPGRADE clause after you finish upgrading the application.
  - You must specify the same *app\_name* that you specified for the corresponding BEGIN UPGRADE clause.
  - You need not specify TO *end\_app\_version*, but if you do, then you must specify the same version that you specified for the corresponding BEGIN UPGRADE clause.

### UNINSTALL Clauses

Use the UNINSTALL clauses when uninstalling an application from an application container. The current container must be the application root, not an application PDB.

- Specify the BEGIN UNINSTALL clause before you start uninstalling the application.
  - For *app\_name*, specify the name of the application you want to uninstall.
- Specify the END UNINSTALL clause after you have finished uninstalling the application.
  - You must specify the same *app\_name* that you specified for the corresponding BEGIN UNINSTALL clause.

### SET PATCH

Use the SET PATCH clause to register the patch number of an application that is already installed in an application container. This clause allows you to assign a patch number to an application that was not patched using the PATCH clauses. This is useful if the application was migrated from a PDB in an earlier Oracle Database release, when the PATCH clauses were not available. The current container can be the application root or an application PDB.

- For *app\_name*, specify the name of an existing application.
- Use *number* to assign a patch number to the existing application.

### SET VERSION

Use the SET VERSION clause to register the version of an application that is already installed in an application container. This clause allows you to assign a name and a version to an application that was not installed using the INSTALL clauses. This is useful if the application was migrated from a PDB in an earlier Oracle Database release, when the INSTALL clauses were not available. The current container can be the application root or an application PDB.

- Use *app\_name* to assign a name to the existing application.
- Use *app\_version* to assign a version to the existing application.

### SET COMPATIBILITY VERSION

Use the SET COMPATIBILITY VERSION clause to set the compatibility version for an application.

The compatibility version of an application is the earliest version of the application possible for the application PDBs that belong to the application container. The current container must be the application root, not an application PDB.

#### Note:

You cannot plug in an application PDB that uses an application version earlier than the compatibility setting of the application container.

- Use *app\_name* to specify the name of the application.
- Use *app\_version* to specify the compatibility version for the application.
- If you specify CURRENT, then the compatibility version is set to the version of the application in the application root.

The compatibility version is enforced when the compatibility version is set and when an application PDB is created. If there are application root clones that resulted from application upgrades, then all application root clones that correspond to versions earlier than the compatibility version are implicitly dropped.

## SYNC TO

You can synchronize an application to a particular version or a patch number. There are two variations:

1. SYNC TO *version\_string*
2. SYNC TO PATCH *patch\_number*

### Example

Assume that you perform the following operations on application salesapp :

1. Install version 1.0
2. Patch 101
3. Upgrade to version 2.0
4. Patch 102
5. Upgrade to 3.0

ALTER PLUGGABLE DATABASE APPLICATION salesapp SYNC TO 2.0 replays all statements up to and including 'Upgrade to version 2.0'.

ALTER PLUGGABLE DATABASE APPLICATION salesapp SYNC TO PATCH 102 replays all statements up to and including 'Patch 102'.

### Restrictions on SYNC TO

You can use SYNC TO only with an individual application.

You cannot use SYNC TO with the ALL SYNC clause.

You cannot use SYNC TO with the SYNC clause, in the case when you are synchronizing multiple applications in a single statement.

## SYNC

Use the SYNC clause to synchronize an application in an application PDB to the version and patch level of the same application in the application root. The current container must be an application PDB.

*app\_name* specifies the name of an application that exists in the application root. The application may or may not exist in the application PDB.

Starting with Oracle Database Release 21c you can synchronize multiple applications in one statement with SYNC . This is necessary to preserve functional correctness for applications that depend on one another.

### Example

```
ALTER PLUGGABLE DATABASE APPLICATION hrapp payrollapp employeesapp SYNC
```

### Restrictions on Synchronizing Multiple Applications Using SYNC

- You cannot use the SYNC TO *version\_string* clause while synchronizing multiple applications with SYNC.
- You cannot use the SYNC TO PATCH *patch\_number* clause while synchronizing multiple applications with SYNC.

## ALL SYNC

Use the ALL SYNC clause to sync all applications in an application PDB with all applications in the application root. This clause is useful, if you have recently added the application PDB to the CDB and would like to sync its applications with the CDB. The current container must be an application PDB.

With Release 21c you can use EXCEPT to exclude applications from ALL SYNC.

### Example

```
ALTER PLUGGABLE DATABASE APPLICATION ALL EXCEPT hrapp payrollapp SYNC
```

### Restrictions on Excluding Multiple Applications Using ALL SYNC

- You cannot use the SYNC TO *version\_string* clause while excluding multiple applications with ALL EXCEPT SYNC.
- You cannot use the SYNC TO PATCH *patch\_number* clause while excluding multiple applications with ALL EXCEPT SYNC.

### *snapshot\_clauses*

The snapshot clauses allow you to create and manage snapshots of the PDB for the lifetime of the PDB.

#### *pdb\_snapshot\_clause*

Specify this clause to enable the creation of PDB snapshots. You can also specify this clause in the CREATE PLUGGABLE DATABASE statement.

- NONE is the default and means that no snapshots of the PDB can be created.
- MANUAL means that a snapshot of the PDB can be created only manually.
- If *snapshot\_interval* is specified, PDB snapshots will be created automatically at the interval specified. In addition, a user will also be able to create PDB snapshots manually.
- If expressed in minutes, the *snapshot\_interval* must be less than 3000.
- If expressed in hours, the *snapshot\_interval* must be less than 2000.

#### *materialize\_clause*

Use this clause to convert a snapshot PDB into a full PDB clone. You can delete and purge a PDB snapshot using the clause in this way.

- This clause can only be specified for PDBs created as a snapshot.
- All blocks in all datafiles belonging to the PDB will be copied.

#### *create\_snapshot\_clause*

Use this clause to manually create a PDB snapshot after connecting to the PDB.

- This statement may be issued even if the PDB was set to have PDB snapshots created automatically.
- If a PDB Snapshot with the specified name already exists, an error will be reported.
- A PDB Snapshot with specified name will be created.

#### ***drop\_snapshot\_clause***

Use this clause to manually drop a PDB snapshot after connecting to the PDB.

- If this snapshot is being used by some PDB, an error will be reported.

#### ***set\_max\_pdb\_snapshots***

Use this clause to increase or decrease the maximum number of snapshots for a given PDB. You must first connect to the PDB.

- If the PDB is not open in read/write mode when issuing the statement, an error is raised.
- You can drop all PDB snapshots by setting the max number to 0.
- The maximum number of snapshots that you can set per PDB is 8.

#### ***prepare\_clause***

- Use this clause to prepare mirror copies of the database. You must provide a *mirror\_name* to identify the filegroup that is created. The created filegroup contains all the prepared files.
- Specify the number of copies to be prepared by the REDUNDANCY options: EXTERNAL, NORMAL, or HIGH.
- If you do not specify the redundancy of the mirror, the redundancy of the source database is used.
- Use the FOR DATABASE clause to specify the new name of the CDB. This name should be unique. It will be used in the *create\_pdb\_from\_mirror\_copy* clause of the CREATE PLUGGABLE DATABASE statement.

#### **Prepare a Pluggable Database By Name: Example**

If you specify the name (*pdb\_name*) of the pluggable database, it checks if *pdb\_name* matches with the current PDB. If it matches, it runs.

```
ALTER PLUGGABLE DATABASE pdb_name PREPARE MIRROR COPY mirror_name WITH HIGH  
REDUNDANCY
```

#### **Prepare a Pluggable Database Without a Name: Example**

If you do not specify the name (*pdb\_name*) of the pluggable database, the statement runs on the current PDB.

```
ALTER PLUGGABLE DATABASE PREPARE MIRROR COPY mirror_name WITH HIGH REDUNDANCY
```

#### ***drop\_mirror\_copy***

Use this clause to discard mirror copies of data and metadata created by the prepare statement. You must specify the same mirror name that you used for the prepare operation.

You cannot use this clause to drop a database that has already been split by the CREATE DATABASE or CREATE PLUGGABLE DATABASE statement.

#### ***lost\_write\_protection***

#### **Turn on Lost Write for a Pluggable Database : Example**

```
ALTER PLUGGABLE DATABASE
    ENABLE LOST WRITE PROTECTION
```

### Turn off Lost Write for a Pluggable Database : Example

```
ALTER PLUGGABLE DATABASE
    DISABLE LOST WRITE PROTECTION
```

Note that disabling lost write for the database does not deallocate the lost write storage. You must use the `DROP TABLESPACE` statement to deallocate lost write storage.

### *pdb\_managed\_recovery*

Specify this clause to recover a PDB in instances where the PDB is within a physical standby CDB.

### Examples

#### Unplugging a PDB from a CDB: Example

The following statement unplugs PDB `pdb1` and stores metadata for the PDB into XML file / `oracle/data/pdb1.xml`:

```
ALTER PLUGGABLE DATABASE pdb1
    UNPLUG INTO '/oracle/data/pdb1.xml';
```

#### Modifying the Settings of a PDB: Example

The following statement changes the limit for the amount of storage used by all tablespaces in PDB `pdb2` to 500M:

```
ALTER PLUGGABLE DATABASE pdb2
    STORAGE (MAXSIZE 500M);
```

#### Taking the Data Files of a PDB Offline: Example

The following statement takes the data files associated with PDB `pdb3` offline:

```
ALTER PLUGGABLE DATABASE pdb3
    DATAFILE ALL OFFLINE;
```

#### Changing the State of a PDB: Examples

Assume that PDB `pdb4` is closed—that is, its open mode is MOUNTED. The following statement opens `pdb4` with open mode READ ONLY:

```
ALTER PLUGGABLE DATABASE pdb4
    OPEN READ ONLY;
```

The following statement uses the FORCE keyword to change the open mode of `pdb4` from READ ONLY to READ WRITE:

```
ALTER PLUGGABLE DATABASE pdb4
    OPEN READ WRITE FORCE;
```

The following statement closes PDB `pdb4`:

```
ALTER PLUGGABLE DATABASE pdb4
    CLOSE;
```

The following statement opens PDB pdb4 with open mode READ ONLY. Because the RESTRICTED keyword is specified, the PDB is accessible only to users with the RESTRICTED SESSION privilege in the PDB.

```
ALTER PLUGGABLE DATABASE pdb4
  OPEN READ ONLY RESTRICTED;
```

Assume that PDB pdb5 is closed—that is, its open mode is MOUNTED. In an Oracle Real Application Clusters environment, the following statement opens PDB pdb5 with open mode READ WRITE in instances ORCLDB\_1 and ORCLDB\_2:

```
ALTER PLUGGABLE DATABASE pdb5
  OPEN READ WRITE INSTANCES = ('ORCLDB_1', 'ORCLDB_2');
```

In an Oracle Real Application Clusters environment, the following statement closes PDB pdb6 in the current instance and instructs the database to reopen pdb6 in instance ORCLDB\_3:

```
ALTER PLUGGABLE DATABASE pdb6
  CLOSE RELOCATE TO 'ORCLDB_3';
```

### Changing the State of All PDBs in a CDB: Example

Assume that the current container is the root. The following statement opens all PDBs in the CDB with open mode READ ONLY:

```
ALTER PLUGGABLE DATABASE ALL
  OPEN READ ONLY;
```

## ALTER PMEM FILESTORE

### Purpose

Use this command to change the attributes of a PMEM file store.

### Prerequisites

You cannot change the block size of a PMEM file store.

### Syntax

***alter\_pmem\_filestore***

## Semantics

### MOUNT

Use this command to mount a PMEM file store. If you have already specified the mount point and backing file paths in the `init.ora` file you can issue the command like this:

```
ALTER PMEM FILESTORE 'filestore_name' MOUNT
```

You can also specify the mount point and backing file paths in the command line. In this case, you must ensure that there is no mismatch between the values in the `init.ora` file and the values you specify in the command line. The command fails when a mismatch occurs, unless you specify `FORCE` to override the values in the `init.ora` file. The paths on the command line become the new paths for the PMEM file store.

If you use a `spfile`, then the parameters are automatically updated with the new paths specified on the command line.

Use the `mount PMEM file store` command in cases when the PMEM file store was not already automatically mounted during database startup.

Specify the mount point path or the backing file path on the command line when:

- You have not specified either the mount point path or the backing file path in the `init.ora` file
- You want to specify new values for either the mount point path or the backing file path

Before you can change the mount point and the backing file, you must first dismount the file store.

### DISMOUNT

Use this command to dismount a PMEM file store. You must ensure that the database instance is in `NOMOUNT` mode.

### Examples

#### **Example 1: Resize File Store Named `cloud_db_1`**

```
ALTER PMEM FILESTORE cloud_db_1 RESIZE 5T
```

#### **Example 2: Mount File Store Named `cloud_db_1`**

```
ALTER PMEM FILESTORE cloud_db_1 MOUNT MOUNTPOINT '/corp/db/cloud_db_1'  
BACKINGFILE '/var/pmem/foo_1'
```

#### **Example 3: Dismount File Store Named `cloud_db_1`**

```
ALTER PMEM FILESTORE cloud_db_1 DISMOUNT
```

# ALTER PROCEDURE

## Purpose

Packages are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `ALTER PROCEDURE` statement to explicitly recompile a standalone stored procedure. Explicit recompilation eliminates the need for implicit run-time recompilation and prevents associated run-time compilation errors and performance overhead.

To recompile a procedure that is part of a package, recompile the entire package using the `ALTER PACKAGE` statement (see [ALTER PACKAGE](#) ).

### Note:

This statement does not change the declaration or definition of an existing procedure. To redeclare or redefine a procedure, use the `CREATE PROCEDURE` statement with the `OR REPLACE` clause (see [CREATE PROCEDURE](#) ).

The `ALTER PROCEDURE` statement is quite similar to the `ALTER FUNCTION` statement. Refer to [ALTER FUNCTION](#) for more information.

## Prerequisites

The procedure must be in your own schema or you must have `ALTER ANY PROCEDURE` system privilege.

## Syntax

`alter_procedure ::=`

(`procedure_compile_clause`: See *Oracle Database PL/SQL Language Reference* for the syntax of this clause.)

## Semantics

### IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

***schema***

Specify the schema containing the procedure. If you omit *schema*, then Oracle Database assumes the procedure is in your own schema.

***procedure\_name***

Specify the name of the procedure to be recompiled.

***procedure\_compile\_clause***

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling procedures.

**EDITIONABLE | NONEDITIONABLE**

Use these clauses to specify whether the procedure becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `PROCEDURE` in *schema*. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

## ALTER PROFILE

**Purpose**

Use the `ALTER PROFILE` statement to add, modify, or remove a resource limit or password management parameter in a profile.

Changes made to a profile with an `ALTER PROFILE` statement affect users only in their subsequent sessions, not in their current sessions.

 **See Also:**

[CREATE PROFILE](#) for information on creating a profile

**Prerequisites**

You must have the `ALTER PROFILE` system privilege.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root. To specify `CONTAINER = CURRENT`, the current container must be a pluggable database (PDB).

**Syntax**

***alter\_profile::=***

(*resource\_parameters ::=, password\_parameters ::=*)

*resource\_parameters ::=*

(*size\_clause ::=*)

*password\_parameters ::=*

## Semantics

The keywords, parameters, and clauses common to ALTER PROFILE and CREATE PROFILE have the same meaning. For full semantics of these keywords, parameters, and clauses refer to [CREATE PROFILE](#).

Only common users who have been commonly granted the ALTER PROFILE system privilege can alter or drop the mandatory profile, and only from the CDB root.

You cannot remove a limit from the DEFAULT profile.

## Examples

### Making a Password Unavailable: Example

The following statement makes the password of the new\_profile profile (created in "[Creating a Profile: Example](#)") unavailable for reuse for 90 days:

```
ALTER PROFILE new_profile
  LIMIT PASSWORD_REUSE_TIME 90
    PASSWORD_REUSE_MAX UNLIMITED;
```

### Setting Default Password Values: Example

The following statement defaults the PASSWORD\_REUSE\_TIME value of the app\_user profile (created in "[Setting Profile Resource Limits: Example](#)") to its defined value in the DEFAULT profile:

```
ALTER PROFILE app_user
  LIMIT PASSWORD_REUSE_TIME DEFAULT
    PASSWORD_REUSE_MAX UNLIMITED;
```

### Limiting Login Attempts and Password Lock Time: Example

The following statement alters profile app\_user with FAILED\_LOGIN\_ATTEMPTS set to 5 and PASSWORD\_LOCK\_TIME set to 1:

```
ALTER PROFILE app_user LIMIT
  FAILED_LOGIN_ATTEMPTS 5
    PASSWORD_LOCK_TIME 1;
```

This statement causes any user account to which the app\_user profile is assigned to become locked for one day after five consecutive unsuccessful login attempts.

### Changing Password Lifetime and Grace Period: Example

The following statement modifies the profile app\_user2 PASSWORD\_LIFE\_TIME to 90 days and PASSWORD\_GRACE\_TIME to 5 days:

```
ALTER PROFILE app_user2 LIMIT
  PASSWORD_LIFE_TIME 90
    PASSWORD_GRACE_TIME 5;
```

### Limiting Account Inactivity: Example

The following statement modifies the profile app\_user2 INACTIVE\_ACCOUNT\_TIME to 30 consecutive days:

```
ALTER PROFILE app_user2 LIMIT
  INACTIVE_ACCOUNT_TIME 30;
```

If the account has already been inactive for a certain number of days, then those days count toward the new 30 day limit.

### **Limiting Concurrent Sessions: Example**

This statement defines a new limit of 5 concurrent sessions for the `app_user` profile:

```
ALTER PROFILE app_user LIMIT SESSIONS_PER_USER 5;
```

If the `app_user` profile does not currently define a limit for `SESSIONS_PER_USER`, then the preceding statement adds the limit of 5 to the profile. If the profile already defines a limit, then the preceding statement redefines it to 5. Any user assigned the `app_user` profile is subsequently limited to 5 concurrent sessions.

### **Removing Profile Limits: Example**

This statement removes the `IDLE_TIME` limit from the `app_user` profile:

```
ALTER PROFILE app_user LIMIT IDLE_TIME DEFAULT;
```

Any user assigned the `app_user` profile is subject in their subsequent sessions to the `IDLE_TIME` limit defined in the `DEFAULT` profile.

### **Limiting Profile Idle Time: Example**

This statement defines a limit of 2 minutes of idle time for the `DEFAULT` profile:

```
ALTER PROFILE default LIMIT IDLE_TIME 2;
```

This `IDLE_TIME` limit applies to these users:

- Users who are not explicitly assigned any profile
- Users who are explicitly assigned a profile that does not define an `IDLE_TIME` limit

This statement defines unlimited idle time for the `app_user2` profile:

```
ALTER PROFILE app_user2 LIMIT IDLE_TIME UNLIMITED;
```

Any user assigned the `app_user2` profile is subsequently permitted unlimited idle time.

### **Enable Gradual Password Rollover: Example**

This statement sets the password rollover time to 2 days in the profile `usr_prof`:

```
ALTER PROFILE usr_prof LIMIT PASSWORD_ROLLOVER_TIME 2 ;
```

## **ALTER PROPERTY GRAPH**

### **Purpose**

Changes to the underlying objects of the property graph may cause the property graph to be in an invalid state. You can revalidate a graph with `ALTER PROPERTY GRAPH COMPILE`.

### **Prerequisites**

To alter a property graph in any schema except `SYS` and `AUDSYS`, you must have the `ALTER ANY PROPERTY GRAPH` privilege.

## Syntax

***alter\_property\_graph::=***

## Semantics

### IF EXISTS

Specify **IF EXISTS** to alter an existing property graph.

If you specify **IF NOT EXISTS** with **ALTER**, the command fails with the error message:  
Incorrect IF EXISTS clause for ALTER/DROP statement.

### COMPILE

Use **ALTER PROPERTY GRAPH COMPILE** to revalidate a graph that reports an invalid state even though it is actually valid. This happens because the dependencies of the graph to its underlying objects may be too coarse. In such cases, it may be enough to use **ALTER PROPERTY GRAPH COMPILE** to revalidate the property graph.

### Example: How a Valid Graph May Falsely Report an Invalid State

```
SQL> create table tbl1(c1 number primary key, c2 number, c3 number, c4 as (c2/c3), c5 as (1 / (c2+c3)));
```

Table created.

```
SQL> create property graph g vertex tables(tbl1 properties(c2, c3, c5));
```

Property graph created.

```
SQL> select object_name, object_type, status from user_objects where object_type in ('PROPERTY GRAPH', 'TABLE');
```

OBJECT_NAME	OBJECT_TYPE	STATUS
G	PROPERTY GRAPH	VALID
TBL1	TABLE	VALID

```
SQL> alter table tbl1 drop column c4;
```

Table altered.

```
SQL> select object_name, object_type, status from user_objects where object_type in ('PROPERTY GRAPH', 'TABLE');
```

OBJECT_NAME	OBJECT_TYPE	STATUS
G	PROPERTY GRAPH	INVALID
TBL1	TABLE	VALID

```
SQL> alter property graph g compile;  
  
Property graph altered.  
  
SQL> select object_name, object_type, status from user_objects where  
object_type in ('PROPERTY GRAPH', 'TABLE');  
  
OBJECT_NAME OBJECT_TYPE STATUS  
-----  
G PROPERTY GRAPH VALID  
TBL1 TABLE VALID  
  
SQL>
```

If ALTER PROPERTY GRAPH COMPILE fails to revalidate the graph, then the graph enters the error state. You must then redefine the graph with CREATE OR REPLACE PROPERTY GRAPH .

## ALTER RESOURCE COST

### Purpose

Use the ALTER RESOURCE COST statement to specify or change the formula by which Oracle Database calculates the total resource cost used in a session.

Although Oracle Database monitors the use of other resources, only the four resources shown in the syntax can contribute to the total resource cost for a session.

This statement lets you apply weights to the four resources. Oracle Database then applies the weights to the value of these resources that were specified for a profile to establish a formula for calculating total resource cost. You can limit this cost for a session with the COMPOSITE\_LIMIT parameter of the CREATE PROFILE statement. If the resource cost of a session exceeds the limit, then Oracle Database aborts the session and returns an error. If you use the ALTER RESOURCE COST statement to change the weight assigned to each resource, then Oracle Database uses these new weights to calculate the total resource cost for all current and subsequent sessions.

#### See Also:

[CREATE PROFILE](#) for information on all resources and on establishing resource limits

### Prerequisites

You must have the ALTER RESOURCE COST system privilege.

**Syntax**

```
alter_resource_cost::=
```

**Semantics**

Oracle Database calculates the total resource cost by first multiplying the amount of each resource used in the session by the weight of the resource, and then summing the products for all four resources. For any session, this cost is limited by the value of the `COMPOSITE_LIMIT` parameter in the user's profile. Both the products and the total cost are expressed in units called **service units**.

**CPU\_PER\_SESSION**

Use this keyword to apply a weight to the `CPU_PER_SESSION` resource.

**CONNECT\_TIME**

Use this keyword to apply a weight to the `CONNECT_TIME` resource.

**LOGICAL\_READS\_PER\_SESSION**

Use this clause to apply a weight to the `LOGICAL_READS_PER_SESSION` resource. Logical reads include blocks read from both memory and disk.

**PRIVATE\_SGA**

Use this clause to apply a weight to the `PRIVATE_SGA` resource. This limit applies only if you are using shared server architecture and allocating private space in the SGA for your session.

**integer**

Specify the weight of each resource. The weight that you assign to each resource determines how much the use of that resource contributes to the total resource cost. If you do not assign a weight to a resource, then the weight defaults to 0, and use of the resource subsequently does not contribute to the cost. The weights you assign apply to all subsequent sessions in the database.

**Examples****Altering Resource Costs: Examples**

The following statement assigns weights to the resources `CPU_PER_SESSION` and `CONNECT_TIME`:

```
ALTER RESOURCE COST
  CPU_PER_SESSION 100
  CONNECT_TIME    1;
```

The weights establish this cost formula for a session:

```
cost = (100 * CPU_PER_SESSION) + (1 * CONNECT_TIME)
```

In this example, the values of `CPU_PER_SESSION` and `CONNECT_TIME` are either values in the `DEFAULT` profile or in the profile of the user of the session.

Because the preceding statement assigns no weight to the resources `LOGICAL_READS_PER_SESSION` and `PRIVATE_SGA`, these resources do not appear in the formula.

If a user is assigned a profile with a `COMPOSITE_LIMIT` value of 500, then a session exceeds this limit whenever `cost` exceeds 500. For example, a session using 0.04 seconds of CPU time and 101 minutes of elapsed time exceeds the limit. A session using 0.0301 seconds of CPU time and 200 minutes of elapsed time also exceeds the limit.

You can subsequently change the weights with another `ALTER RESOURCE` statement:

```
ALTER RESOURCE COST
  LOGICAL_READS_PER_SESSION 2
  CONNECT_TIME 0;
```

These new weights establish a new cost formula:

```
cost = (100 * CPU_PER_SESSION) + (2 * LOGICAL_READ_PER_SECOND)
```

where the values of `CPU_PER_SESSION` and `LOGICAL_READS_PER_SECOND` are either the values in the `DEFAULT` profile or in the profile of the user of this session.

This `ALTER RESOURCE COST` statement changes the formula in these ways:

- The statement omits a weight for the `CPU_PER_SESSION` resource. That resource was already assigned a weight, so the resource remains in the formula with its original weight.
- The statement assigns a weight to the `LOGICAL_READS_PER_SESSION` resource, so this resource now appears in the formula.
- The statement assigns a weight of 0 to the `CONNECT_TIME` resource, so this resource no longer appears in the formula.
- The statement omits a weight for the `PRIVATE_SGA` resource. That resource was not already assigned a weight, so the resource still does not appear in the formula.

## ALTER ROLE

### Purpose

Use the `ALTER ROLE` statement to change the authorization needed to enable a role.

**See Also:**

- [CREATE ROLE](#) for information on creating a role
- [SET ROLE](#) for information on enabling or disabling a role for your session

**Prerequisites**

You must either have been granted the role with the `ADMIN OPTION` or have `ALTER ANY ROLE` system privilege.

Before you alter a role to `IDENTIFIED GLOBALLY`, you must:

- Revoke all grants of roles identified externally to the role and
- Revoke the grant of the role from all users, roles, and `PUBLIC`.

The one exception to this rule is that you should not revoke the role from the user who is currently altering the role.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root. To specify `CONTAINER = CURRENT`, the current container must be a pluggable database (PDB).

**Syntax**

***alter\_role ::=***

**Semantics**

The keywords, parameters, and clauses in the `ALTER ROLE` statement all have the same meaning as in the `CREATE ROLE` statement.

Specify `GLOBALLY` with `AS` to map a directory group to a global role when using centrally managed users. The directory group is identified by its domain name.

**Restriction on Altering a Role**

You cannot alter a NOT IDENTIFIED role to any of the IDENTIFIED types if it is granted to another role.

#### Notes on Altering a Role:

- User sessions in which the role is already enabled are not affected.
- If you change a role identified by password to an application role (with the USING package clause), then password information associated with the role is lost. Oracle Database will use the new authentication mechanism the next time the role is to be enabled.
- If you have the ALTER ANY ROLE system privilege and you change a role that is IDENTIFIED GLOBALLY to IDENTIFIED BY password, IDENTIFIED EXTERNALLY, or NOT IDENTIFIED, then Oracle Database grants you the altered role with the ADMIN OPTION, as it would have if you had created the role identified nonglobally.

For more information, refer to [CREATE ROLE](#) and to the examples that follow.

#### Examples

##### Changing Role Identification: Example

The following statement changes the role `warehouse_user` (created in "[Creating a Role: Example](#)") to NOT IDENTIFIED:

```
ALTER ROLE warehouse_user NOT IDENTIFIED;
```

##### Changing a Role Password: Example

This statement changes the password on the `dw_manager` role (created in "[Creating a Role: Example](#)") to `data`:

```
ALTER ROLE dw_manager
  IDENTIFIED BY data;
```

Users granted the `dw_manager` role must subsequently use the new password `data` to enable the role.

##### Application Roles: Example

The following example changes the `dw_manager` role to an application role using the `hr.admin` package:

```
ALTER ROLE dw_manager IDENTIFIED USING hr.admin;
```

## ALTER ROLLBACK SEGMENT

### Note:

Oracle strongly recommends that you run your database in automatic undo management mode instead of using rollback segments. Do not use rollback segments unless you must do so for compatibility with earlier versions of Oracle Database. Refer to *Oracle Database Administrator's Guide* for information on automatic undo management.

## Purpose

Use the ALTER ROLLBACK SEGMENT statement to bring a rollback segment online or offline, change its storage characteristics, or shrink it to an optimal or specified size.

This section assumes that your database is running in rollback undo mode (the UNDO\_MANAGEMENT initialization parameter is set to MANUAL or not set at all). If your database is running in automatic undo mode (the UNDO\_MANAGEMENT initialization parameter is set to AUTO, which is the default), then user-created rollback segments are irrelevant.

### See Also:

- [CREATE ROLLBACK SEGMENT](#) for information on creating a rollback segment
- *Oracle Database Reference* for information on the UNDO\_MANAGEMENT parameter

## Prerequisites

You must have the ALTER ROLLBACK SEGMENT system privilege.

## Syntax

***alter\_rollback\_segment::=***

**(*storage\_clause* , *size\_clause*::=)**

## Semantics

### ***rollback\_segment***

Specify the name of an existing rollback segment.

### **ONLINE**

Specify ONLINE to bring the rollback segment online. When you create a rollback segment, it is initially offline and not available for transactions. This clause brings the rollback segment online, making it available for transactions by your instance. You can also bring a rollback segment online when you start your instance with the initialization parameter ROLLBACK\_SEGMENTS.

 **See Also:**

"[Bringing a Rollback Segment Online: Example](#)"

## OFFLINE

Specify `OFFLINE` to take the rollback segment offline.

- If the rollback segment does not contain any information needed to roll back an active transaction, then Oracle Database takes it offline immediately.
- If the rollback segment does contain information for active transactions, then the database makes the rollback segment unavailable for future transactions and takes it offline after all the active transactions are committed or rolled back.

When the rollback segment is offline, it can be brought online by any instance.

To see whether a rollback segment is online or offline, query `STATUS` column of the data dictionary view `DBA_ROLLBACK_SEGS`. Online rollback segments have a value of `IN_USE`. Offline rollback segments have a value of `AVAILABLE`.

### Restriction on Taking Rollback Segments Offline

You cannot take the `SYSTEM` rollback segment offline.

#### *storage\_clause*

Use the `storage_clause` to change the storage characteristics of the rollback segment.

### Restrictions on Rollback Segment Storage

You cannot change the value of `INITIAL` parameter. If the rollback segment is in a locally managed tablespace, then the only storage parameter you can change is `OPTIMAL`. If the rollback segment is in a dictionary-managed tablespace, then the only storage parameters you can change are `NEXT`, `MINEXTENTS`, `MAXEXTENTS` and `OPTIMAL`.

 **See Also:**

`storage_clause` for syntax and additional information

## SHRINK Clause

Specify `SHRINK` if you want Oracle Database to attempt to shrink the rollback segment to an optimal or specified size. The success and amount of shrinkage depend on the available free space in the rollback segment and how active transactions are holding space in the rollback segment.

If you do not specify `TO size_clause`, then the size defaults to the `OPTIMAL` value of the `storage_clause` of the `CREATE ROLLBACK SEGMENT` statement that created the rollback segment. If `OPTIMAL` was not specified, then the size defaults to the `MINEXTENTS` value of the `storage_clause` of the `CREATE ROLLBACK SEGMENT` statement.

Regardless of whether you specify `TO size_clause`:

- The value to which Oracle Database shrinks the rollback segment is valid for the execution of the statement. Thereafter, the size reverts to the OPTIMAL value of the CREATE ROLLBACK SEGMENT statement.
- The rollback segment cannot shrink to less than two extents.

To determine the actual size of a rollback segment after attempting to shrink it, query the BYTES, BLOCKS, and EXTENTS columns of the DBA\_SEGMENTS view.

### Restriction on Shrinking Rollback Segments

In an Oracle Real Application Clusters environment, you can shrink only rollback segments that are online to your instance.

#### See Also:

[size\\_clause](#) for information on that clause, and "Resizing a Rollback Segment: Example"

## Examples

The following examples use the rbs\_one rollback segment, which was created in "Creating a Rollback Segment: Example".

### Bringing a Rollback Segment Online: Example

This statement brings the rollback segment rbs\_one online:

```
ALTER ROLLBACK SEGMENT rbs_one ONLINE;
```

### Resizing a Rollback Segment: Example

This statement shrinks the rollback segment rbs\_one:

```
ALTER ROLLBACK SEGMENT rbs_one
    SHRINK TO 100M;
```

# ALTER SEQUENCE

## Purpose

Use the ALTER SEQUENCE statement to change the increment, minimum and maximum values, cached numbers, and behavior of an existing sequence. This statement affects only future sequence numbers.

#### See Also:

[CREATE SEQUENCE](#) for additional information on sequences

## Prerequisites

The sequence must be in your own schema, or you must have the ALTER object privilege on the sequence, or you must have the ALTER ANY SEQUENCE system privilege.

## Syntax

**alter\_sequence ::=**

## Semantics

The keywords and parameters in this statement serve the same purposes they serve when you create a sequence.

- If you change the `INCREMENT BY` value before the first invocation of `NEXTVAL`, then some sequence numbers will be skipped. Therefore, if you want to retain the original `START WITH` value, you must drop the sequence and re-create it with the original `START WITH` value and the new `INCREMENT BY` value.
- Specify `RESTART` to reset `NEXTVAL` to `MINVALUE` for an ascending sequence. For a descending sequence `RESTART` resets `NEXTVAL` to `MAXVALUE`.

- To restart the sequence at a different number, specify `RESTART` with the `START WITH` clause to set the value at which the sequence restarts.
- If you alter the sequence by specifying the `KEEP` or `NOKEEP` clause between runtime and failover of a request, then the original value of `NEXTVAL` is not retained during replay for Application Continuity for that request.
- Oracle Database performs some validations. For example, a new `MAXVALUE` cannot be imposed that is less than the current sequence number.

#### See Also:

[CREATE SEQUENCE](#) for information on creating a sequence and [DROP SEQUENCE](#) for information on dropping and re-creating a sequence

### IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### SCALE

Use `SCALE` to enable sequence scalability. When `SCALE` is specified, a numeric offset is affixed to the beginning of the sequence which removes all duplicates in generated values.

### EXTEND

If you specify `EXTEND` with `SCALE` the generated sequence values are all of length  $(x+y)$ , where  $x$  is the length of the scalable offset (default value is 6), and  $y$  is the maximum number of digits in the sequence (`maxvalue/minvalue`).

When you use `SCALE` it is highly recommended that you not use `ORDER` simultaneously on the sequence.

### NOEXTEND

`NOEXTEND` is the default setting for the `SCALE` clause. With the `NOEXTEND` setting, the generated sequence values are at most as wide as the maximum number of digits in the sequence (`maxvalue/minvalue`). This setting is useful for integration with existing applications where sequences are used to populate fixed width columns.

### SHARD

Use this clause to generate unique sequence numbers across shards.

The sequence object is created as a global, all-shards sharded object that returns unique sequence values across all shards. The sequence object is also created at the catalog database that returns unique sequence values relative to the shard databases.

The `EXTEND` and `NOEXTEND` keywords define the behavior of a sharded sequence.

## EXTEND

When you specify EXTEND with the SHARD clause, the generated sequence values are all of length  $(x + y)$ , where  $x$  is the length of an(a) SHARD offset of size 4. The size 4 corresponds to the width of the maximum number of shards i.e. 1000 affixed at the beginning of the sequence values.  $y$  is the maximum number of digits in the sequence *maxvalue/minvalue*.

## NOEXTEND

The default setting for the SHARD clause is NOEXTEND.

When you specify NOEXTEND, the generated sequence values are at most as wide as the maximum number of digits in the sequence *maxvalue/minvalue*. This setting is useful for integration with existing applications where sequences are used to populate fixed width columns.

If you call NEXTVAL on a sequence with SHARD NOEXTEND specified, a user error is thrown, if the generated value requires more digits of representation than the *maxvalue/minvalue* of the sequence.

## Sequence with SHARD and SCALE

If you specify the SCALE and the SHARD clauses together, the sequence generates scalable, globally unique values within a shard database for multiple instances and sessions.

If you specify EXTEND with the SCALE and SHARD clauses, the generated sequence values are all of length  $(x+y+z)$ , where  $x$  is the length of a SHARD offset with a default value of size 4,  $y$  is the length of the scalable offset with a default value of 6(5), and  $z$  is the maximum number of digits in the sequence *maxvalue/minvalue*.

If you specify EXTEND or NOEXTEND with the SHARD and SCALE clauses, it applies to both SHARD and SCALE. You do not need to specify EXTEND or NOEXTEND separately. If you specify the EXTEND or NOEXTEND option separately for both the SHARD and SCALE clauses, with the same or different value, a parsing error results, with a message of a duplicate or conflicting EXTEND clause.

When you use SHARD it is highly recommended that you not use ORDER simultaneously on the sequence.

You can use SHARD with CACHE and NOCACHE modes of operation.

## Examples

### Modifying a Sequence: Examples

This statement sets a new maximum value for the `customers_seq` sequence, which was created in "[Creating a Sequence: Example](#)":

```
ALTER SEQUENCE customers_seq
    MAXVALUE 1500;
```

This statement turns on CYCLE and CACHE for the `customers_seq` sequence:

```
ALTER SEQUENCE customers_seq
    CYCLE
    CACHE 5;
```

# ALTER SESSION

## Purpose

Use the `ALTER SESSION` statement to set or modify any of the conditions or parameters that affect your connection to the database. The statement stays in effect until you disconnect from the database.

## Prerequisites

To enable and disable the SQL trace facility, you must have `ALTER SESSION` system privilege.

To enable or disable resumable space allocation, you must have the `RESUMABLE` system privilege.

You do not need any privileges to perform the other operations of this statement unless otherwise indicated.

## Syntax

`alter_session ::=`

**`alter_session_set_clause::=`**

## Semantics

### ADVISE Clause

The `ADVISE` clause sends advice to a remote database to force a distributed transaction. The advice appears in the `ADVICE` column of the `DBA_2PC_PENDING` view on the remote database (the values are 'C' for `COMMIT`, 'R' for `ROLLBACK`, and ' ' for `NOTHING`). If the transaction becomes in doubt, then the administrator of that database can use this advice to decide whether to commit or roll back the transaction.

You can send different advice to different remote databases by issuing multiple `ALTER SESSION` statements with the `ADVISE` clause in a single transaction. Each such statement sends advice to the databases referenced in the following statements in the transaction until another such statement is issued.

#### See Also:

["Forcing a Distributed Transaction: Example"](#)

### CLOSE DATABASE LINK Clause

Specify `CLOSE DATABASE LINK` to close the database link `dblink`. When you issue a statement that uses a database link, Oracle Database creates a session for you on the remote database using that link. The connection remains open until you end your local session or until the number of database links for your session exceeds the value of the initialization parameter `OPEN_LINKS`. If you want to reduce the network overhead associated with keeping the link open, then use this clause to close the link explicitly if you do not plan to use it again in your session.

#### See Also:

[Closing a Database Link: Example](#)

## ENABLE | DISABLE COMMIT IN PROCEDURE

Procedures and stored functions written in PL/SQL can issue COMMIT and ROLLBACK statements. If your application would be disrupted by a COMMIT or ROLLBACK statement not issued directly by the application itself, then specify DISABLE COMMIT IN PROCEDURE clause to prevent procedures and stored functions called during your session from issuing these statements.

You can subsequently allow procedures and stored functions to issue COMMIT and ROLLBACK statements in your session by issuing the ENABLE COMMIT IN PROCEDURE.

Some applications automatically prohibit COMMIT and ROLLBACK statements in procedures and stored functions. Refer to your application documentation for more information.

## ENABLE | DISABLE GUARD

The *security\_clause* of ALTER DATABASE lets you prevent anyone other than the SYS user from making any changes to data or database objects on the primary or standby database. This clause lets you override that setting for the current session.

### See Also:

[security\\_clause](#) for more information on the GUARD setting

## PARALLEL DML | DDL | QUERY

The PARALLEL parameter determines whether all subsequent DML, DDL, or query statements in the session will be considered for parallel execution. This clause enables you to override the degree of parallelism of tables during the current session without changing the tables themselves. Uncommitted transactions must either be committed or rolled back prior to executing this clause for DML.

### See Also:

["Enabling Parallel DML: Example"](#)

## ENABLE Clause

Specify ENABLE to execute subsequent statements in the session in parallel. This is the default for DDL and query statements.

- DML: DML statements are executed in parallel mode if a parallel hint or a parallel clause is specified.
- DDL: DDL statements are executed in parallel mode if a parallel clause is specified.
- QUERY: Queries are executed in parallel mode if a parallel hint or a parallel clause is specified.

## Restriction on the ENABLE clause

You cannot specify the optional PARALLEL *integer* with ENABLE.

## DISABLE Clause

Specify `DISABLE` to execute subsequent statements in the session serially. This is the default for DML statements.

- `DML`: DML statements are executed serially.
- `DDL`: DDL statements are executed serially.
- `QUERY`: Queries are executed serially.

### Restriction on the DISABLE clause

You cannot specify the optional `PARALLEL integer` with `DISABLE`.

## FORCE Clause

`FORCE` forces parallel execution of subsequent statements in the session. If no parallel clause or hint is specified, then a default degree of parallelism is used. This clause overrides any `parallel_clause` specified in subsequent statements in the session but is overridden by a parallel hint.

- `DML`: Provided no parallel DML restrictions are violated, subsequent DML statements in the session are executed with the default degree of parallelism, unless a degree is specified in this clause.
- `DDL`: Subsequent DDL statements in the session are executed with the default degree of parallelism, unless a degree is specified in this clause. Resulting database objects will have associated with them the prevailing degree of parallelism.

Specifying `FORCE DDL` automatically causes all tables created in this session to be created with a default level of parallelism. The effect is the same as if you had specified the `parallel_clause` (with the default degree) in the `CREATE TABLE` statement.

- `QUERY`: Subsequent queries are executed with the default degree of parallelism, unless a degree is specified in this clause.

## PARALLEL *integer*

Specify an integer to explicitly specify a degree of parallelism:

- For `FORCE DDL`, the degree overrides any parallel clause in subsequent DDL statements.
- For `FORCE DML` and `QUERY`, the degree overrides the degree currently stored for the table in the data dictionary.
- A degree specified in a statement through a hint will override the degree being forced.

The following types of DML operations are not parallelized regardless of this clause:

- Operations on cluster tables
- Operations with embedded functions that either write or read database or package states
- Operations on tables with triggers that could fire
- Operations on tables or schema objects containing object types, or `LONG` or `LOB` data types

## RESUMABLE Clauses

These clauses let you enable and disable resumable space allocation. This feature allows an operation to be suspended in the event of an out-of-space error condition and to resume automatically from the point of interruption when the error condition is fixed.

### Note:

Resumable space allocation is fully supported for operations on locally managed tablespaces. Some restrictions apply if you are using dictionary-managed tablespaces. For information on these restrictions, refer to *Oracle Database Administrator's Guide*.

## ENABLE RESUMABLE

This clause enables resumable space allocation for the session.

### TIMEOUT

TIMEOUT lets you specify (in seconds) the time during which an operation can remain suspended while waiting for the error condition to be fixed. If the error condition is not fixed within the TIMEOUT period, then Oracle Database aborts the suspended operation.

### NAME

NAME lets you specify a user-defined text string to help users identify the statements issued during the session while the session is in resumable mode. Oracle Database inserts the text string into the `USER_RESUMABLE` and `DBA_RESUMABLE` data dictionary views. If you do not specify NAME, then Oracle Database inserts the default string '`User username(userid), Session sessionid, Instance instanceid`'.

### See Also:

*Oracle Database Reference* for information on the data dictionary views

## DISABLE RESUMABLE

This clause disables resumable space allocation for the session.

### SHARD DDL Clauses

These clauses are valid only if you are connected to a sharded database. They let you control whether DDLs issued in the session are issued against the shard catalog database and all shards, or against only the shard catalog database.

- If you specify `ENABLE SHARD DDL`, then DDLs issued in the session are issued against the shard catalog database and all shards. This mode is the default for the SDB user—a user that exists in the shard catalog database and in all shards.
- If you specify `DISABLE SHARD DDL`, then DDLs issued in the session are issued against only the shard catalog database. This mode is the default for a local user—a user that exists only in the shard catalog database.

 See Also:

*Using Oracle Sharding*

## SYNC WITH PRIMARY

Use this clause to synchronize redo apply on a physical standby database with the primary database. An `ALTER SESSION` statement with this clause blocks until redo apply has applied all redo data received by the standby at the time the statement is issued. This clause returns an error, and synchronization does not occur, if the redo transport state for the standby database is not `SYNCHRONIZED` or if redo apply is not active.

 See Also:

*Oracle Data Guard Concepts and Administration* for more information on this session parameter

## `alter_session_set_clause`

Use the `alter_session_set_clause` to set initialization parameter values or to set an edition for the current session.

### Initialization Parameters

You can set two types of parameters using this clause:

- Initialization parameters that are dynamic in the scope of the `ALTER SESSION` statement (listed in "[Initialization Parameters and ALTER SESSION](#)")
- Session parameters (listed in "[Session Parameters and ALTER SESSION](#)")

You can set values for multiple parameters in the same `alter_session_set_clause`.

### EDITION

Specify `EDITION = edition` to set the specified edition as the edition in the database session. You must have the `USE` object privilege on `edition`, `edition` must already have been created, and it must be `USABLE`.

When this statement is successful, the database discards PL/SQL package state corresponding to editionable packages but retains package state corresponding to packages that are not editionable.

You can also set the edition for the current session at startup with the `EDITION` parameter of the SQL\*Plus `CONNECT` command. However, you cannot specify an `ALTER SESSION SET EDITION` statement in a recursive SQL or PL/SQL block.

You can determine the edition in use by the current session with the following query:

```
SELECT SYS_CONTEXT('USERENV', 'CURRENT_EDITION_NAME') FROM DUAL;
```

 See Also:

[CREATE EDITION](#) for more information on editions and *Oracle Database PL/SQL Language Reference* for information on how editions are designated as `USABLE`

## CONTAINER

Use this clause in a multitenant container database (CDB) to switch to the container specified by `container_name`.

To use this clause, you must be a common user with the `SET CONTAINER` privilege, either granted commonly or granted locally in `container_name`.

For `container_name`, specify one of the following:

- `CDB$ROOT` to switch to the root
- `PDB$SEED` to switch to the seed
- A pluggable database (PDB) name to switch to that PDB. You can view the names of the PDBs in a CDB by querying the `DBA_PDBS` view.

You can determine the container to which the current session is connected by using the SQL\*Plus `SHOW CON_NAME` command or with the following SQL query:

```
SELECT SYS_CONTEXT('USERENV', 'CON_NAME') FROM DUAL;
```

## SERVICE

By default, when you switch to a container, the session uses the default service for the container. Specify the `SERVICE` clause to use a different service for the container. For `service_name`, specify the name of the service you want to use.

 See Also:

[Oracle Database Administrator's Guide](#) for more information on switching to a container

## ROW ARCHIVAL VISIBILITY

Use this clause to configure row archival visibility for the session. This clause lets you implement In-Database Archiving, which allows you to designate table rows as active or archived. You can then perform queries on only the active rows within the table.

- If you specify `ACTIVE`, then the database will consider only active rows when performing queries on tables that are enabled for row archival. This is the default.
- If you specify `ALL`, then the database will consider all rows when performing queries on tables that are enabled for row archival.

This clause has no effect on queries on tables that are not enabled for row archival.

 See Also:

- The CREATE TABLE [ROW ARCHIVAL](#) clause to learn how to enable a new table for row archival
- The ALTER TABLE [\[NO\] ROW ARCHIVAL](#) clause to learn how to enable or disable an existing table for row archival
- *Oracle Database VLDB and Partitioning Guide* for more information on In-Database Archiving

## DEFAULT\_COLLATION

Use this clause to set the default collation for the session.

- Use *collation\_name* to specify the default collation for the session. You can specify the name of any valid named collation or pseudo-collation. This collation becomes the *effective schema default collation*. This collation is assigned to tables, views, and materialized views that are subsequently created in any schema for the duration of the session. The default collation for the session does not get propagated to any remote sessions connected to the current session using DB links.
- If you specify `NONE`, then there is no default collation for the session. In this case, the default collation for a particular schema becomes the *effective schema default collation* for that schema. That default collation is assigned to tables, views, and materialized views that are subsequently created in the schema for the duration of the session.

In either of the preceding cases, you can override the effective schema default collation and assign a default collation to a particular table, materialized view, or view by specifying the `DEFAULT COLLATION` clause of the `CREATE` or `ALTER` statement for the table, materialized view, or view.

The effective schema default collation also affects the DDL statements `CREATE FUNCTION`, `CREATE PACKAGE`, `CREATE PROCEDURE`, `CREATE TRIGGER`, and `CREATE TYPE`. Refer to *Oracle Database PL/SQL Language Reference* for more details on these statements.

You can query the default collation for a session with the following statement:

```
SELECT SYS_CONTEXT('USERENV', 'SESSION_DEFAULT_COLLATION') FROM DUAL;
```

You can specify the `SET DEFAULT_COLLATION` clause only if the `COMPATIBLE` initialization parameter is set to 12.2 or greater, and the `MAX_STRING_SIZE` initialization parameter is set to EXTENDED.

 See Also:

The [DEFAULT COLLATION Clause](#) clause of `CREATE USER` for more information on the default collation of a schema

 **Note:**

The effective schema default collation for a session should not be confused with the session parameter `NLS_SORT`. The effective schema default collation is used by DDL statements to decide the default data-bound collation of tables, views, and materialized views when they are created. The session parameter `NLS_SORT` points to a named collation that is used when Oracle executes a query, a DML statement, or PL/SQL code containing a SQL operation whose determined collation is a pseudo-collation, such as `USING_NLS_COMP` or `USING_NLS_SORT`. Refer to *Oracle Database Globalization Support Guide* for more information.

## Initialization Parameters and ALTER SESSION

Some initialization parameters are dynamic in the scope of `ALTER SESSION`. When you set these parameters using `ALTER SESSION`, the value you set persists only for the duration of the current session. To determine whether a parameter can be altered using an `ALTER SESSION` statement, query the `ISSES_MODIFIABLE` column of the `V$PARAMETER` dynamic performance view.

 **Note:**

Before changing the values of initialization parameters, refer to their full description in *Oracle Database Reference*.

A number of parameters that can be set using `ALTER SESSION` are not initialization parameters. You can set them only with `ALTER SESSION`, not in an initialization parameter file. Those session parameters are described in "[Session Parameters and ALTER SESSION](#)".

## Session Parameters and ALTER SESSION

The following parameters are session parameters only, not initialization parameters:

### **CONSTRAINT[S]**

#### **Syntax:**

```
CONSTRAINT[S] = { IMMEDIATE | DEFERRED | DEFAULT }
```

The `CONSTRAINT[S]` parameter determines when conditions specified by a deferrable constraint are enforced.

- `IMMEDIATE` indicates that the conditions specified by the deferrable constraint are checked immediately after each DML statement. This setting is equivalent to issuing the `SET CONSTRAINTS ALL IMMEDIATE` statement at the beginning of each transaction in your session.
- `DEFERRED` indicates that the conditions specified by the deferrable constraint are checked when the transaction is committed. This setting is equivalent to issuing the `SET`

CONSTRAINTS ALL DEFERRED statement at the beginning of each transaction in your session.

- DEFAULT restores all constraints at the beginning of each transaction to their initial state of DEFERRED or IMMEDIATE.

## CURRENT\_SCHEMA

### Syntax:

```
CURRENT_SCHEMA = schema
```

The CURRENT\_SCHEMA parameter changes the current schema of the session to the specified schema. Subsequent unqualified references to schema objects during the session will resolve to objects in the specified schema. The setting persists for the duration of the session or until you issue another ALTER SESSION SET CURRENT\_SCHEMA statement.

This setting offers a convenient way to perform operations on objects in a schema other than that of the current user without having to qualify the objects with the schema name. This setting changes the current schema, but it does not change the session user or the current user, nor does it give the session user any additional system or object privileges for the session.

## ERROR\_ON\_OVERLAP\_TIME

### Syntax:

```
ERROR_ON_OVERLAP_TIME = {TRUE | FALSE}
```

The ERROR\_ON\_OVERLAP\_TIME parameter determines how Oracle Database should handle an ambiguous boundary datetime value—a case in which it is not clear whether the datetime is in standard or daylight saving time.

- Specify TRUE to return an error for the ambiguous overlap timestamp.
- Specify FALSE to default the ambiguous overlap timestamp to the standard time. This is the default.

Refer to "[Support for Daylight Saving Times](#)" for more information on boundary datetime values.

## FLAGGER

### Syntax:

```
FLAGGER = { ENTRY | OFF }
```

The FLAGGER parameter specifies FIPS flagging (as specified in Federal Information Processing Standard 127-2), which causes an error message to be generated when a SQL statement issued is an extension of the Entry Level of SQL-92 (officially, ANSI X3.135-1992, a standard that is now superseded by SQL:2016). FLAGGER is a session parameter only, not an initialization parameter.

After flagging is set in a session, a subsequent ALTER SESSION SET FLAGGER statement will work, but generates the message, ORA-00097. This allows FIPS flagging to be altered without disconnecting the session. OFF turns off flagging.

 **See Also:**

[Oracle and Standard SQL](#), for more information about Oracle compliance with current ANSI SQL standards

Starting with Oracle Database 23c, several parameters associated with `FIPS_140` are deprecated.

`FIPS_140` in `FIPS.ORA` can be used to enable `FIPS` for all features starting with Oracle Database 23c. The following FIPS parameters are deprecated:

- `SQLNET.ORA`: `FIPS_140` to enable FIPS for native network encryption
- `FIPS.ORA`: `SSLFIPS_140` to enable FIPS for TLS
- Initialization parameter: `DBFIPS_140` to enable FIPS for TDE and `DBMS_CRYPTO`

## INSTANCE

**Syntax:**

```
INSTANCE = integer
```

Setting the `INSTANCE` parameter lets you access another instance as if you were connected to your own instance. `INSTANCE` is a session parameter only, not an initialization parameter. In an Oracle Real Application Clusters (Oracle RAC) environment, each Oracle RAC instance retains static or dynamic ownership of disk space for optimal DML performance based on the setting of this parameter.

## ISOLATION\_LEVEL

**Syntax:**

```
ISOLATION_LEVEL = {SERIALIZABLE | READ COMMITTED}
```

The `ISOLATION_LEVEL` parameter specifies how transactions containing database modifications are handled. `ISOLATION_LEVEL` is a session parameter only, not an initialization parameter.

- `SERIALIZABLE` indicates that transactions in the session use the serializable transaction isolation mode as specified in the SQL standard. If a serializable transaction attempts to execute a DML statement that updates rows currently being updated by another uncommitted transaction at the start of the serializable transaction, then the DML statement fails. A serializable transaction can see its own updates.
- `READ COMMITTED` indicates that transactions in the session will use the default Oracle Database transaction behavior. If the transaction contains DML that requires row locks held by another transaction, then the DML statement will wait until the row locks are released.

 **Note:**

Serializable transactions do not work with deferred segment creation or interval partitioning. Trying to insert data into an empty table with no segment created, or into a partition of an interval partitioned table that does not yet have a segment, causes an error.

## STANDBY\_MAX\_DATA\_DELAY

**Syntax:**

```
STANDBY_MAX_DATA_DELAY = { integer | NONE }
```

In an Active Data Guard environment, this session parameter can be used to specify a session-specific apply lag tolerance, measured in seconds, for queries issued by non-administrative users to a physical standby database that is in real-time query mode. This capability allows queries to be safely offloaded from the primary database to a physical standby database, because it is possible to detect if the standby database has become unacceptably stale.

If STANDBY\_MAX\_DATA\_DELAY is set to the default value of NONE, queries issued to a physical standby database will be executed regardless of the apply lag on that database.

If STANDBY\_MAX\_DATA\_DELAY is set to a nonzero value, a query issued to a physical standby database will be executed only if the apply lag is less than or equal to STANDBY\_MAX\_DATA\_DELAY. Otherwise, an ORA-3172 error is returned to alert the client that the apply lag is too large.

If STANDBY\_MAX\_DATA\_DELAY is set to 0, a query issued to a physical standby database is guaranteed to return the exact same result as if the query were issued on the primary database, unless the standby database is lagging behind the primary database, in which case an ORA-3172 error is returned.

 **See Also:**

*Oracle Data Guard Concepts and Administration* for more information on Active Data Guard and using this session parameter

## TIME\_ZONE

**Syntax:**

```
TIME_ZONE = '+|- hh:mi'  
          | LOCAL  
          | DBTIMEZONE  
          | 'time_zone_region'
```

The TIME\_ZONE parameter specifies the default local time zone offset or region name for the current SQL session. TIME\_ZONE is a session parameter only, not an initialization parameter. To determine the time zone of the current session, query the built-in function SESSIONTIMEZONE (see [SESSIONTIMEZONE](#) ).

- Specify a format mask ('[+|-] hh:mi') indicating the hours and minutes before or after UTC (Coordinated Universal Time—formerly Greenwich Mean Time). The valid range for *hh:mi* is -12:00 to +14:00.
- Specify `LOCAL` to set the default local time zone offset of the current SQL session to the original default local time zone offset that was established when the current SQL session was started.
- Specify `DBTIMEZONE` to set the current session time zone to match the value set for the database time zone. If you specify this setting, then the `DBTIMEZONE` function will return the database time zone as a UTC offset or a time zone region, depending on how the database time zone has been set.
- Specify a valid *time\_zone\_region*. To see a listing of valid time zone region names, query the `TZNAME` column of the `V$TIMEZONE_NAMES` dynamic performance view. If you specify this setting, then the `SESSIONTIMEZONE` function will return the region name.

 **Note:**

Time zone region names are needed by the daylight saving feature. These names are stored in two types of time zone files: one large and one small. One of these files is the default file, depending on your environment and the release of Oracle Database you are using. For more information regarding time zone files and names, see *Oracle Database Globalization Support Guide*.

 **See Also:**

*Oracle Database Globalization Support Guide* for a complete listing of the time zone region names in both files

 **Note:**

You can also set the default client session time zone using the `ORA_SDTZ` environment variable. Refer to *Oracle Database Globalization Support Guide* for more information on this variable.

## USE\_PRIVATE\_OUTLINES

**Syntax:**

```
USE_PRIVATE_OUTLINES = { TRUE | FALSE | category_name }
```

The `USE_PRIVATE_OUTLINES` parameter lets you control the use of private outlines. When this parameter is enabled and an outlined SQL statement is issued, the optimizer retrieves the outline from the session private area rather than the public area used when `USE_STORED_OUTLINES` is enabled. If no outline exists in the session private area, then the optimizer will not use an outline to compile the statement. `USE_PRIVATE_OUTLINES` is not an initialization parameter.

- TRUE causes the optimizer to use private outlines stored in the DEFAULT category when compiling requests.
- FALSE specifies that the optimizer should not use stored private outlines. This is the default. If USE\_STORED\_OUTLINES is enabled, then the optimizer will use stored public outlines.
- *category\_name* causes the optimizer to use outlines stored in the *category\_name* category when compiling requests.

#### Restriction on USE\_PRIVATE\_OUTLINES

You cannot enable this parameter if USE\_STORED\_OUTLINES is enabled.

#### USE\_STORED\_OUTLINES

##### Note:

Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. Refer to *Oracle Database SQL Tuning Guide* for more information about SQL plan management.

#### Syntax:

```
USE_STORED_OUTLINES = { TRUE | FALSE | category_name }
```

The USE\_STORED\_OUTLINES parameter determines whether the optimizer will use stored public outlines to generate execution plans. USE\_STORED\_OUTLINES is not an initialization parameter.

- TRUE causes the optimizer to use outlines stored in the DEFAULT category when compiling requests.
- FALSE specifies that the optimizer should not use stored outlines. This is the default.
- *category\_name* causes the optimizer to use outlines stored in the *category\_name* category when compiling requests.

#### Restriction on USED\_STORED\_OUTLINES

You cannot enable this parameter if USE\_PRIVATE\_OUTLINES is enabled.

#### Examples

##### Enabling Parallel DML: Example

Issue the following statement to enable parallel DML mode for the current session:

```
ALTER SESSION ENABLE PARALLEL DML;
```

##### Forcing a Distributed Transaction: Example

The following transaction inserts an employee record into the employees table on the database identified by the database link `remote` and deletes an employee record from the employees table on the database identified by `local`:

```
ALTER SESSION
    ADVISE COMMIT;

INSERT INTO employees@remote
VALUES (8002, 'Juan', 'Fernandez', 'juanf@example.com', NULL,
TO_DATE('04-OCT-1992', 'DD-MON-YYYY'), 'SA_CLERK', 3000,
NULL, 121, 20);

ALTER SESSION
    ADVISE ROLLBACK;

DELETE FROM employees@local
WHERE employee_id = 8002;

COMMIT;
```

This transaction has two ALTER SESSION statements with the ADVISE clause. If the transaction becomes in doubt, then `remote` is sent the advice 'COMMIT' by virtue of the first ALTER SESSION statement and `local` is sent the advice 'ROLLBACK' by virtue of the second statement.

### Closing a Database Link: Example

This statement updates the `jobs` table on the `local` database using a database link, commits the transaction, and explicitly closes the database link:

```
UPDATE jobs@local SET min_salary = 3000
WHERE job_id = 'SH_CLERK';

COMMIT;
```

```
ALTER SESSION
    CLOSE DATABASE LINK local;
```

### Changing the Date Format Dynamically: Example

The following statement dynamically changes the default date format for your session to '`YYYY MM DD-HH24:MI:SS`':

```
ALTER SESSION
    SET NLS_DATE_FORMAT = 'YYYY MM DD HH24:MI:SS';
```

Oracle Database uses the new default date format:

```
SELECT TO_CHAR(SYSDATE) Today
FROM DUAL;

TODAY
-----
2001 04 12 12:30:38
```

### Changing the Date Language Dynamically: Example

The following statement changes the language for date format elements to French:

```
ALTER SESSION
    SET NLS_DATE_LANGUAGE = French;

SELECT TO_CHAR(SYSDATE, 'Day DD Month YYYY') Today
FROM DUAL;

TODAY
```

```
-----  
Jeudi 12 Avril 2001
```

### Changing the ISO Currency: Example

The following statement dynamically changes the ISO currency symbol to the ISO currency symbol for the territory America:

```
ALTER SESSION  
  SET NLS_ISO_CURRENCY = America;  
  
SELECT TO_CHAR( SUM(salary), 'C999G999D99') Total  
  FROM employees;  
  
TOTAL  
-----  
USD694,900.00
```

### Changing the Decimal Character and Group Separator: Example

The following statement dynamically changes the decimal character to comma (,) and the group separator to period (.):

```
ALTER SESSION SET NLS_NUMERIC_CHARACTERS = ',.' ;
```

Oracle Database returns these new characters when you use their number format elements:

```
ALTER SESSION SET NLS_CURRENCY = 'FF';  
  
SELECT TO_CHAR( SUM(salary), 'L999G999D99') Total FROM employees;  
  
TOTAL  
-----  
FF694.900,00
```

### Changing the NLS Currency: Example

The following statement dynamically changes the local currency symbol to 'DM':

```
ALTER SESSION  
  SET NLS_CURRENCY = 'DM';  
  
SELECT TO_CHAR( SUM(salary), 'L999G999D99') Total  
  FROM employees;  
  
TOTAL  
-----  
DM694.900,00
```

### Changing the NLS Language: Example

The following statement dynamically changes to French the language in which error messages are displayed:

```
ALTER SESSION  
  SET NLS_LANGUAGE = FRENCH;  
  
Session modifiee.  
  
SELECT * FROM DMP;
```

ORA-00942: Table ou vue inexistante

### Changing the Linguistic Sort Sequence: Example

The following statement dynamically changes the linguistic sort sequence to Spanish:

```
ALTER SESSION
    SET NLS_SORT = XSpanish;
```

Oracle Database sorts character values based on their position in the Spanish linguistic sort sequence.

### Enabling Query Rewrite: Example

This statement enables query rewrite in the current session for all materialized views that have not been explicitly disabled:

```
ALTER SESSION
    SET QUERY_REWRITE_ENABLED = TRUE;
```

# 12

## SQL Statements: ALTER SYNONYM to COMMENT

This chapter contains the following SQL statements:

- [ALTER SYNONYM](#)
- [ALTER SYSTEM](#)
- [ALTER TABLE](#)
- [ALTER TABLESPACE](#)
- [ALTER TABLESPACE SET](#)
- [ALTER TRIGGER](#)
- [ALTER TYPE](#)
- [ALTER USER](#)
- [ALTER VIEW](#)
- [ANALYZE](#)
- [ASSOCIATE STATISTICS](#)
- [AUDIT \(Traditional Auditing\)](#)
- [AUDIT \(Unified Auditing\)](#)
- [CALL](#)
- [COMMENT](#)

### ALTER SYNONYM

#### Purpose

Use the `ALTER SYNONYM` statement to modify an existing synonym.

#### Prerequisites

To modify a private synonym in another user's schema, you must have the `CREATE ANY SYNONYM` and `DROP ANY SYNONYM` system privileges.

To modify a `PUBLIC` synonym, you must have the `CREATE PUBLIC SYNONYM` and `DROP PUBLIC SYNONYM` system privileges.

## Syntax

**alter\_synonym ::=**

## Semantics

### PUBLIC

Specify `PUBLIC` if *synonym* is a public synonym. You cannot use this clause to change a public synonym to a private synonym, or vice versa.

### IF EXISTS

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### schema

Specify the schema containing the synonym. If you omit *schema*, then Oracle Database assumes the synonym is in your own schema.

### synonym

Specify the name of the synonym to be altered.

### EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the synonym becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `SYNONYM` in *schema*. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

### Restriction on EDITIONABLE | NONEDITIONABLE

You cannot specify these clauses for a public synonym because editioning is always enabled for the object type `SYNONYM` in the `PUBLIC` schema.

### COMPILE

Use this clause to compile *synonym*. A synonym places a dependency on its target object and becomes invalid if the target object is changed or dropped. When you compile an invalid synonym, it becomes valid again.

 **Note:**

You can determine if a synonym is valid or invalid by querying the STATUS column of the ALL\_, DBA\_, and USER\_OBJECTS data dictionary views.

## Examples

The following examples modify synonyms that were created in the CREATE SYNONYM "Examples".

The following statement compiles synonym `offices`:

```
ALTER SYNONYM offices COMPILE;
```

The following statement compiles public synonym `emp_table`:

```
ALTER PUBLIC SYNONYM emp_table COMPILE;
```

The following statement causes synonym `offices` to remain a noneditioned object if editioning is later enabled for schema object type SYNONYM in the schema that contains the synonym `offices`:

```
ALTER SYNONYM offices NONEDITIONABLE;
```

# ALTER SYSTEM

## Purpose

Use the ALTER SYSTEM statement to dynamically alter your Oracle Database instance. The settings stay in effect as long as the database is mounted.

When you use the ALTER SYSTEM statement in a multitenant container database (CDB), you can specify some clauses to alter the CDB as a whole and other clauses to alter a specific pluggable database (PDB).

 **See Also:**

*Oracle Database Administrator's Guide* for complete information on using the ALTER SYSTEM statement in a CDB

## Prerequisites

To specify the RELOCATE CLIENT clause, you must be authenticated AS SYSASM.

To specify all other clauses, you must have the ALTER SYSTEM system privilege.

If you are connected to a CDB:

- To alter the CDB as a whole, the current container must be the root and you must have the commonly granted ALTER SYSTEM privilege.

- To alter a PDB, the current container must be the PDB and you must have the ALTER SYSTEM privilege, either granted commonly or granted locally in the PDB.

### Syntax

***alter\_system::=***

(*archive\_log\_clause ::=, checkpoint\_clause ::=, check\_datafiles\_clause ::=,  
 distributed\_recov\_clauses ::=, end\_session\_clauses ::=, quiesce\_clauses ::=,  
 rolling\_migration\_clauses ::=, rolling\_patch\_clauses ::=, security\_clauses ::=,  
 shutdown\_dispatcher\_clause ::=, alter\_system\_set\_clause ::=,  
 alter\_system\_reset\_clause ::=*)

***archive\_log\_clause ::=***

***checkpoint\_clause ::=***

***check\_datafiles\_clause ::=***

***distributed\_recov\_clauses ::=***

*flush\_clause*

*end\_session\_clauses::=*

*quiesce\_clauses::=*

*rolling\_migration\_clauses::=*

*rolling\_patch\_clauses ::=*

*security\_clauses ::=*

*affinity\_clauses ::=*

*set\_encryption\_key ::=*

*shutdown\_dispatcher\_clause ::=*

***alter\_system\_set\_clause ::=***

***set\_parameter\_clause ::=***

***alter\_system\_reset\_clause ::=***

***cancel\_sql\_clause ::=***

## Semantics

### ***archive\_log\_clause***

The *archive\_log\_clause* manually archives redo log files or enables or disables automatic archiving. To use this clause, your instance must have the database mounted. The database can be either open or closed unless otherwise noted.

### **INSTANCE Clause**

This clause is relevant only if you are using Oracle Real Application Clusters (Oracle RAC). Specify the name of the instance for which you want the redo log file group to be archived. The instance name is a string of up to 80 characters. Oracle Database automatically determines the thread that is mapped to the specified instance and archives the corresponding redo log file group. If no thread is mapped to the specified instance, then Oracle Database returns an error.

### **SEQUENCE Clause**

Specify **SEQUENCE** to manually archive the online redo log file group identified by the log sequence number *integer* in the specified thread. If you omit the **THREAD** parameter, then Oracle Database archives the specified group from the thread assigned to your instance.

### **CHANGE Clause**

Specify **CHANGE** to manually archive the online redo log file group containing the redo log entry with the system change number (SCN) specified by *integer* in the specified thread. If the SCN is in the current redo log file group, then Oracle Database performs a log switch. If you omit the **THREAD** parameter, then Oracle Database archives the groups containing this SCN from all enabled threads.

You can use this clause only when your instance has the database open.

### **CURRENT Clause**

Specify **CURRENT** to manually archive the current redo log file group of the specified thread, forcing a log switch. If you omit the **THREAD** parameter, then Oracle Database archives all redo log file groups from all enabled threads, including logs previous to current logs. You can specify **CURRENT** only when the database is open.

### **NOSWITCH**

Specify **NOSWITCH** if you want to manually archive the current redo log file group without forcing a log switch. This setting is used primarily with standby databases to prevent data divergence when the primary database shuts down. Divergence implies the possibility of data loss in case of primary database failure.

You can use the **NOSWITCH** clause only when your instance has the database mounted but not open. If the database is open, then this operation closes the database automatically. You must then manually shut down the database before you can reopen it.

### **GROUP Clause**

Specify **GROUP** to manually archive the online redo log file group with the **GROUP** value specified by *integer*. You can determine the **GROUP** value for a redo log file group by querying the dynamic performance view **V\$LOG**. If you specify both the **THREAD** and **GROUP** parameters, then the specified redo log file group must be in the specified thread.

### **LOGFILE Clause**

Specify `LOGFILE` to manually archive the online redo log file group containing the redo log file member identified by '`filename`'. If you specify both the `THREAD` and `LOGFILE` parameters, then the specified redo log file group must be in the specified thread.

If the database was mounted with a backup control file, then specify `USING BACKUP CONTROLFILE` to permit archiving of all online logfiles, including the current logfile.

#### Restriction on the `LOGFILE` clause

You must archive redo log file groups in the order in which they are filled. If you specify a redo log file group for archiving with the `LOGFILE` parameter, and earlier redo log file groups are not yet archived, then Oracle Database returns an error.

#### NEXT Clause

Specify `NEXT` to manually archive the next online redo log file group from the specified thread that is full but has not yet been archived. If you omit the `THREAD` parameter, then Oracle Database archives the earliest unarchived redo log file group from any enabled thread.

#### ALL Clause

Specify `ALL` to manually archive all online redo log file groups from the specified thread that are full but have not been archived. If you omit the `THREAD` parameter, then Oracle Database archives all full unarchived redo log file groups from all enabled threads.

#### TO *location* Clause

Specify `TO 'location'` to indicate the primary location to which the redo log file groups are archived. The value of this parameter must be a fully specified file location following the conventions of your operating system. If you omit this parameter, then Oracle Database archives the redo log file group to the location specified by the initialization parameters `LOG_ARCHIVE_DEST` or `LOG_ARCHIVE_DEST_n`.

#### *checkpoint\_clause*

Specify `CHECKPOINT` to explicitly force Oracle Database to perform a checkpoint, ensuring that all changes made by committed transactions are written to data files on disk. You can specify this clause only when your instance has the database open. Oracle Database does not return control to you until the checkpoint is complete.

#### GLOBAL

In an Oracle Real Application Clusters (Oracle RAC) environment, this setting causes Oracle Database to perform a checkpoint for all instances that have opened the database. This is the default.

#### LOCAL

In an Oracle RAC environment, this setting causes Oracle Database to perform a checkpoint only for the thread of redo log file groups for the instance from which you issue the statement.

#### See Also:

"[Forcing a Checkpoint: Example](#)"

### ***check\_datafiles\_clause***

In a distributed database system, such as an Oracle RAC environment, this clause updates an instance's SGA from the database control file to reflect information on all online data files.

- Specify `GLOBAL` to perform this synchronization for all instances that have opened the database. This is the default.
- Specify `LOCAL` to perform this synchronization only for the local instance.

Your instance should have the database open.

### ***distributed\_recov\_clauses***

The `DISTRIBUTED RECOVERY` clause lets you enable or disable distributed recovery. To use this clause, your instance must have the database open.

#### **ENABLE**

Specify `ENABLE` to enable distributed recovery. In a single-process environment, you must use this clause to initiate distributed recovery.

You may need to issue the `ENABLE DISTRIBUTED RECOVERY` statement more than once to recover an in-doubt transaction if the remote node involved in the transaction is not accessible. In-doubt transactions appear in the data dictionary view `DBA_2PC_PENDING`.

#### **See Also:**

["Enabling Distributed Recovery: Example"](#)

#### **DISABLE**

Specify `DISABLE` to disable distributed recovery.

#### **FLUSH SHARED\_POOL Clause**

The `FLUSH SHARED_POOL` clause lets you clear data from the shared pool in the system global area (SGA). The shared pool stores:

- Cached data dictionary information and
- Shared SQL and PL/SQL areas for SQL statements, stored procedures, functions, packages, and triggers.

This statement does not clear global application context information, nor does it clear shared SQL and PL/SQL areas for items that are currently being executed. You can use this clause regardless of whether your instance has the database dismounted or mounted, open or closed.

#### **See Also:**

["Clearing the Shared Pool: Example"](#)

### FLUSH GLOBAL CONTEXT Clause

The `FLUSH GLOBAL CONTEXT` clause lets you flush all global application context information from the shared pool in the system global area (SGA). You can use this clause regardless of whether your instance has the database dismounted or mounted, open or closed.

### FLUSH BUFFER\_CACHE Clause

The `FLUSH BUFFER_CACHE` clause lets you clear all data from the buffer cache in the system global area (SGA), including the `KEEP`, `RECYCLE`, and `DEFAULT` buffer pools.

Specify `LOCAL` if you only want to flush the local instance. To flush the buffer cache of all instances, specify `GLOBAL`. `GLOBAL` is the default.

 **Note:**

This clause is intended for use only on a test database. Do not use this clause on a production database, because as a result of this statement, subsequent queries will have no hits, only misses.

This clause is useful if you need to measure the performance of rewritten queries or a suite of queries from identical starting points.

### FLUSH FLASH\_CACHE Clause

Use the `FLUSH FLASH_CACHE` clause to flush the Database Smart Flash Cache. This clause can be useful if you need to measure the performance of rewritten queries or a suite of queries from identical starting points, or if there might be corruption in the cache.

Specify `LOCAL` if you only want to flush the local instance. To flush the flash cache of all instances, specify `GLOBAL`. `GLOBAL` is the default.

### FLUSH REDO Clause

Use the `FLUSH REDO` clause to flush redo data from a primary database to a standby database and to optionally wait for the flushed redo data to be applied to a physical or logical standby database.

This clause can allow a failover to be performed on the target standby database without data loss, even if the primary database is not in a zero data loss data protection mode, provided that all redo data that has been generated by the primary database can be flushed to the standby database.

The `FLUSH REDO` clause must be issued on a mounted, but not open, primary database.

#### `target_db_name`

For `target_db_name`, specify the `DB_UNIQUE_NAME` of the standby database that is to receive the redo data flushed from the primary database.

The value of the `LOG_ARCHIVE_DEST_n` database initialization parameter that corresponds to the target standby database must contain the `DB_UNIQUE_NAME`

attribute, and the value of that attribute must match the DB\_UNIQUE\_NAME of the target standby database.

#### NO CONFIRM APPLY

If you specify this clause, then the ALTER SYSTEM statement will not complete until the standby database has received all of the flushed redo data. You must specify this clause if the target standby database is a snapshot standby database.

#### CONFIRM APPLY

If you specify this clause, then the ALTER SYSTEM statement will not complete until the target standby database has received and applied all flushed redo data. This is the default behavior unless you specify NO CONFIRM APPLY. You cannot specify this clause if the target standby database is a snapshot standby database.

#### See Also:

*Oracle Data Guard Concepts and Administration* for more information about the FLUSH REDO clause and failovers

### FLUSH PASSWORDFILE\_METADATA\_CACHE

If the location or the name of the password file changes, you must notify the database that a change has occurred. The command ALTER SYSTEM FLUSH PASSWORDFILE\_METADATA\_CACHE flushes the password file metadata cache stored in the SGA and informs the database that a change has occurred.

The command also flushes the cache from all the RAC instances if it is run in a cluster environment. Note the delay in propagating the change across all instances. Until the flush is fully propagated, some instances might continue to use the old password file.

#### *end\_session\_clauses*

The *end\_session\_clauses* give you several ways to end the current session.

#### DISCONNECT SESSION Clause

Use the DISCONNECT SESSION clause to disconnect the current session by destroying the dedicated server process (or virtual circuit if the connection was made by way of a Shared Server). To use this clause, your instance must have the database open. You must identify the session with both of the following values from the V\$SESSION view:

- For *session\_id*, specify the value of the SID column.
- For *serial\_number*, specify the value of the SERIAL# column.

If system parameters are appropriately configured, then application failover will take effect.

- The POST\_TRANSACTION setting allows ongoing transactions to complete before the session is disconnected. If the session has no ongoing transactions, then this clause has the same effect described for as KILL SESSION.
- The IMMEDIATE setting disconnects the session and recovers the entire session state immediately, without waiting for ongoing transactions to complete.

- If you also specify `POST_TRANSACTION` and the session has ongoing transactions, then the `IMMEDIATE` keyword is ignored.
- If you do not specify `POST_TRANSACTION`, or you specify `POST_TRANSACTION` but the session has no ongoing transactions, then this clause has the same effect as described for `KILL SESSION IMMEDIATE`.

 **See Also:**

["Disconnecting a Session: Example"](#)

### **KILL SESSION Clause**

The `KILL SESSION` clause lets you mark a session as terminated, roll back ongoing transactions, release all session locks, and partially recover session resources. To use this clause, your instance must have the database open. Your session and the session to be terminated must be on the same instance unless you specify `integer3`. You must identify the session with the following values from the `V$SESSION` view:

- For `session_id`, specify the value of the `SID` column.
- For `serial_number`, specify the value of the `SERIAL#` column.
- For the optional `instance_id`, specify the ID of the instance where the target session to be killed exists. You can find the instance ID by querying the `GV$` tables.

If the session is performing some activity that must be completed, such as waiting for a reply from a remote database or rolling back a transaction, then Oracle Database waits for this activity to complete, marks the session as terminated, and then returns control to you. If the waiting lasts a minute, then Oracle Database marks the session to be terminated and returns control to you with a message that the session is marked to be terminated. The `PMON` background process then marks the session as terminated when the activity is complete.

Whether or not the session has an ongoing transaction, Oracle Database does not recover the entire session state until the session user issues a request to the session and receives a message that the session has been terminated.

 **See Also:**

["Terminating a Session: Example"](#)

### **IMMEDIATE**

Specify `IMMEDIATE` to instruct Oracle Database to roll back ongoing transactions, release all session locks, recover the entire session state, and return control to you immediately.

Note that `IMMEDIATE` only returns control immediately, if `TIMEOUT` is not specified.

`IMMEDIATE` is similar to the case when the session is deleted without a modifier in that it waits until the activity completes. Once the activity completes, the full session is deleted without waiting for the session user and the connection is closed.

## FORCE

FORCE is similar to IMMEDIATE except that FORCE will forcefully terminate the connection if a timeout occurs.

### Example

```
ALTER SYSTEM KILL SESSION '20,1' FORCE;
```

## NOREPLAY

This clause is valid if you are using Application Continuity. When connected to a service with Application Continuity enabled (that is, FAILOVER\_TYPE = TRANSACTION), the session is recovered after the session fails or is killed. If you do not want to recover a session after it is terminated, then specify NOREPLAY.

## TIMEOUT

Specify TIMEOUT to set the maximum amount of time (in seconds) to wait before terminating the session. It overrides the default timeout.

The current default timeout values are:

- 60 seconds when no modifier is specified
- 0 seconds when the modifier IMMEDIATE is specified
- 5 seconds when the modifier FORCE is specified

The action that occurs at TIMEOUT is different for IMMEDIATE, which marks the session for termination and FORCE , which forcefully terminates the session.

### Example

```
ALTER SYSTEM KILL SESSION '20,1' TIMEOUT 20;
```

## SWITCH LOGFILE Clause

The SWITCH LOGFILE clause lets you explicitly force Oracle Database to begin writing to a new redo log file group, regardless of whether the files in the current redo log file group are full. When you force a log switch, Oracle Database begins to perform a checkpoint but returns control to you immediately rather than when the checkpoint is complete. To use this clause, your instance must have the database open.

### See Also:

["Forcing a Log Switch: Example"](#)

## SUSPEND | RESUME

The SUSPEND clause lets you suspend all I/O (data file, control file, and file header) as well as queries, in all instances, enabling you to make copies of the database without having to handle ongoing transactions.

### Restrictions on SUSPEND and RESUME

SUSPEND and RESUME are subject to the following restrictions:

- Do not use this clause unless you have put the database tablespaces in hot backup mode.
- Do not terminate the session that issued the `ALTER SYSTEM SUSPEND` statement. An attempt to reconnect while the system is suspended may fail because of recursive SQL that is running during the `SYS` login.
- If you start a new instance while the system is suspended, then that new instance will not be suspended.

The `RESUME` clause lets you make the database available once again for queries and I/O.

### ***quiesce\_clauses***

Use the `QUIESCE RESTRICTED` and `UNQUIESCE` clauses to put the database in and take it out of the **quiesced state**. This state enables database administrators to perform administrative operations that cannot be safely performed in the presence of concurrent transactions, queries, or PL/SQL operations.

#### **Note:**

The `QUIESCE RESTRICTED` clause is valid only if the Database Resource Manager is installed and only if the Resource Manager has been on continuously since database startup in any instances that have opened the database.

If multiple `QUIESCE RESTRICTED` or `UNQUIESCE` statements issue at the same time from different sessions or instances, then all but one will receive an error.

### **QUIESCE RESTRICTED**

Specify `QUIESCE RESTRICTED` to put the database in the quiesced state. For all instances with the database open, this clause has the following effect:

- Oracle Database instructs the Database Resource Manager in all instances to prevent all inactive sessions (other than `SYS` and `SYSTEM`) from becoming active. No user other than `SYS` and `SYSTEM` can start a new transaction, a new query, a new fetch, or a new PL/SQL operation.
- Oracle Database waits for all existing transactions in all instances that were initiated by a user other than `SYS` or `SYSTEM` to finish (either commit or abort). Oracle Database also waits for all running queries, fetches, and PL/SQL procedures in all instances that were initiated by users other than `SYS` or `SYSTEM` and that are not inside transactions to finish. If a query is carried out by multiple successive OCI fetches, then Oracle Database does not wait for all fetches to finish. It waits for the current fetch to finish and then blocks the next fetch. Oracle Database also waits for all sessions (other than those of `SYS` or `SYSTEM`) that hold any shared resources (such as enqueues) to release those resources. After all these operations finish, Oracle Database places the database into quiesced state and finishes executing the `QUIESCE RESTRICTED` statement.
- If an instance is running in shared server mode, then Oracle Database instructs the Database Resource Manager to block logins (other than `SYS` or `SYSTEM`) on that

instance. If an instance is running in non-shared-server mode, then Oracle Database does not impose any restrictions on user logins in that instance.

During the quiesced state, you cannot change the Resource Manager plan in any instance.

### UNQUIESCE

Specify `UNQUIESCE` to take the database out of quiesced state. Doing so permits transactions, queries, fetches, and PL/SQL procedures that were initiated by users other than `SYS` or `SYSTEM` to be undertaken once again. The `UNQUIESCE` statement does not have to originate in the same session that issued the `QUIESCE RESTRICTED` statement.

#### *rolling\_migration\_clauses*

Use these clauses in a clustered Oracle Automatic Storage Management (Oracle ASM) environment to migrate one node at a time to a different Oracle ASM version without affecting the overall availability of the Oracle ASM cluster or the database clusters using Oracle ASM for storage.

### START ROLLING MIGRATION

When starting rolling upgrade, for `ASM_version`, you must specify the following string:

```
'<version_num>, <release_num>, <update_num>,<port_release_num>,<port_update_num>'
```

`ASM_version` must be equal to or greater than 11.1.0.0.0. The surrounding single quotation marks are required. Oracle ASM first verifies that the current release is compatible for migration to the specified release, and then goes into limited functionality mode. Oracle ASM then determines whether any rebalance operations are under way anywhere in the cluster. If there are any such operations, then the statement fails and must be reissued after the rebalance operations are complete.

Rolling upgrade mode is a cluster-wide In-Memory persistent state. The cluster continues to be in this state until there is at least one Oracle ASM instance running in the cluster. Any new instance joining the cluster switches to migration mode immediately upon startup. If all the instances in the cluster terminate, then subsequent startup of any Oracle ASM instance will not be in rolling upgrade mode until you reissue this statement to restart rolling upgrade of the Oracle ASM instances.

### STOP ROLLING MIGRATION

Use this clause to stop rolling upgrade and bring the cluster back into normal operation. Specify this clause only after all instances in the cluster have migrated to the same software version. The statement will fail if the cluster is not in rolling upgrade mode.

When you specify this clause, the Oracle ASM instance validates that all the members of the cluster are at the same software version, takes the instance out of rolling upgrade mode, and returns to full functionality of the Oracle ASM cluster. If any rebalance operations are pending because disks have gone offline, then those operations are restarted if the `ASM_POWER_LIMIT` parameter would not be violated by such a restart.

#### See Also:

*Oracle Automatic Storage Management Administrator's Guide* for more information about rolling upgrade

### ***rolling\_patch\_clauses***

Use these clauses in a clustered Oracle Automatic Storage Management (Oracle ASM) environment to update one node at a time to the latest patch level without affecting the overall availability of the Oracle ASM cluster or the database clusters using Oracle ASM for storage.

#### **START ROLLING PATCH**

Use this clause to start the rolling patch operation. Oracle ASM first verifies that all live nodes in the cluster are at the same version, and then goes into rolling patch mode, which is a cluster-wide In-Memory persistent state. The cluster continues to be in this state until all live nodes have been patched to the latest patch level.

Any nodes that are down during this operation are not patched. This does not affect the success of the rolling patch operation. However, you must patch these nodes before they are started. Otherwise, they will not be allowed to join the cluster.

#### **STOP ROLLING PATCH**

use this clause to stop the rolling patch operation and bring the cluster back into normal operation. Specify this clause only after all live nodes in the cluster have been patched to the latest patch level. The statement will fail if the cluster is not in rolling patch mode.

When you specify this clause, the Oracle ASM instance validates that all members of the cluster are at the same patch level, takes the instance out of rolling patch mode, and returns full functionality of the Oracle ASM cluster. If any members of the cluster are not at the latest patch level, then this operation fails and the cluster goes into limited functionality mode.

The following queries display information about rolling patches. In order to run these queries, you must be connected to the Oracle ASM instance in the Grid home, and the Grid Infrastructure home must be configured with the Oracle Clusterware option for an Oracle RAC environment.

- You can determine whether a cluster is in rolling patch mode with the following query:  

```
SELECT SYS_CONTEXT('SYS_CLUSTER_PROPERTIES', 'CLUSTER_STATE') FROM DUAL;
```
- You can determine the patch level of a cluster with the following query:  

```
SELECT SYS_CONTEXT('SYS_CLUSTER_PROPERTIES', 'CURRENT_PATCHLVL') FROM DUAL;
```
- You can display a list of patches applied on the Oracle ASM instance, by querying the V\$PATCHES dynamic performance view. Refer to *Oracle Database Reference* for more information.

#### **See Also:**

*Oracle Automatic Storage Management Administrator's Guide* for more information about rolling patches

### ***security\_clauses***

The *security\_clauses* let you control access to the instance. They also allow you to enable or disable access to the encrypted data in the instance.

#### **RESTRICTED SESSION**

The RESTRICTED SESSION clause lets you restrict logon to Oracle Database. You can use this clause regardless of whether your instance has the database dismounted or mounted, open or closed.

- Specify `ENABLE` to allow only users with RESTRICTED SESSION system privilege to log on to Oracle Database. Existing sessions are not terminated.  
  
This clause applies only to the current instance. Therefore, in an Oracle RAC environment, authorized users without the RESTRICTED SESSION system privilege can still access the database by way of other instances.
- Specify `DISABLE` to reverse the effect of the `ENABLE RESTRICTED SESSION` clause, allowing all users with CREATE SESSION system privilege to log on to Oracle Database. This is the default.

#### **See Also:**

["Restricting Sessions: Example"](#)

### **SET ENCRYPTION WALLET Clause**

Use this clause to manage database access to the Transparent Data Encryption (TDE) master encryption key. The TDE master encryption key is stored in an external security module, which can be an encryption wallet or Hardware Security Module (HSM).

Although this statement begins with the keyword `ALTER`, an `ALTER SYSTEM SET ENCRYPTION WALLET` statement is not a DDL clause. However, you cannot roll back such a statement.

Although this clause begins with the `SET` keyword, do not confuse it with the `alter_system_set_clause`, which allows you to use the `SET` keyword to set the value of initialization parameters. `ENCRYPTION WALLET` is not an initialization parameter.

#### **OPEN**

When you specify this clause, the database uses the specified password to open the wallet and load the TDE master key into database memory for the duration of the instance, or establish a connection to the HSM in order to send the encrypted table and tablespace keys to the HSM and receive them decrypted.

- Specify `wallet_password` to retrieve the master encryption key from the encryption wallet. If the wallet is not available or is already open, then the database returns an error. The double quotation marks around `wallet_password` are required.
- Specify `HSM_auth_string` to make the HSM accessible. `HSM_auth_string` is of the form "`user_id:password`" where:
  - `user_id` is the user ID created for the database using the HSM management interface

- *password* is the password created for the user ID using the HSM management interface

The double quotation marks around *HSM\_auth\_string* are required

### CLOSE

Use this clause to disable encryption and decryption in your database. The *wallet\_password* is required to close an encryption wallet. *HSM\_auth\_string* is required to disable access to the HSM. Refer to [OPEN](#) for details on specifying *HSM\_auth\_string*.

A password is not required to close an auto-open wallet when only an auto-open wallet is present. The password is required to close an auto-open wallet when both an auto-open wallet and an encryption wallet are open. In this case, using `CLOSE` with a password will close the auto-open wallet and the encryption wallet.

#### See Also:

*Oracle Real Application Clusters Administration and Deployment Guide* for information on setting encryption wallets in an Oracle Real Application Clusters (Oracle RAC) environment

### `set_encryption_key`

Use this clause to generate a new TDE master encryption key, if none exists. If there are existing master keys in the HSM or keystore, then this clause rekeys the existing table and tablespace keys, that is, it decrypts all table and tablespace keys with the old master key and reencrypts them with the new master key.

An `ALTER SYSTEM SET ENCRYPTION KEY` statement is a DDL statement and will automatically commit any pending transactions in the schema.

Although this clause begins with the `SET` keyword, do not confuse it with the [`alter\_system\_set\_clause`](#), which allows you to use the `SET` keyword to set the value of initialization parameters. `ENCRYPTION KEY` is not an initialization parameter.

#### **IDENTIFIED BY *wallet\_password***

This clause loads the TDE master encryption key from the encryption wallet into memory for access to encrypted data.

- The *certificate\_id* is required if you are using PKI asymmetric key pairs as master encryption keys. Specify the integer that identifies the certificate. You can find this value by querying the `CERT_ID` column of the `V$WALLET` dynamic performance view. Do not specify *certificate\_id* if you are using symmetric keys, which are the default.
- For *wallet\_password*, specify the password used to connect to the security module.

If you specify an invalid *certificate\_id* or *wallet\_password*, then the database returns an error. The double quotation marks around *certificate\_id* and *wallet\_password* are required.

#### **Restriction on IDENTIFIED BY *wallet\_password***

PKI-based master keys, including unified master encryption keys, can only be used with TDE column encryption and an Oracle Wallet, not with HSM.

Transparent Data Encryption (TDE) public key infrastructure (PKI) keys are unsupported with Oracle Database 23c.

The deprecation of TDE PKI keys was announced with Oracle Database 12c. Oracle recommends using one of the current TDE keys instead. Follow the documentation to rekey your database with a new TDE key before upgrading the Oracle Database 23c. If the upgrade script detects PKI keys used with TDE, then the script will stop and notify you to rekey the TDE Master Key before upgrade.

 **Note:**

To configure Transparent Data Encryption, use the [ADMINISTER KEY MANAGEMENT](#) statement. See *Oracle Database Advanced Security Guide* for more information.

#### **IDENTIFIED BY *HSM\_auth\_string***

This clause creates a master encryption key that will be stored inside the HSM. The master encryption key is used to encrypt or decrypt table keys inside the HSM.

*HSM\_auth\_string* is of the form "*user\_id:password*" where:

- *user\_id* is the user ID created for the database using the HSM management interface
- *password* is the password created for the user ID using the HSM management interface

The double quotation marks around *HSM\_auth\_string* are required.

If you are already using Transparent Data Encryption with an Oracle Wallet and you would like to migrate to an HSM, then specify the `MIGRATE USING wallet_password` clause. This decrypts the existing table and tablespace keys, and then reencrypts them with the newly created, HSM-based, master encryption key. Note that the wallet is still in use after you migrate to an HSM, because it may contain master encryption keys that were used for export files, RMAN backups, or encrypted data in temporary or undo tablespaces or redo log files. After migrating, perform one of the following steps:

- Change the wallet password to the *HSM\_auth\_string* using Oracle Wallet Manager or the `orapki` command-line tool.
- Create a local auto-open wallet from the encryption wallet and either rename the encryption wallet, or move it out of the directory specified in `ENCRYPTION_WALLET_LOCATION` in `sqlnet.ora`. Do not delete the encryption wallet and do not forget the wallet password.

 See Also:

- The `mkstore` wallet management command line tool is deprecated with Oracle Database 23c, and can be removed in a future release. To manage wallets, Oracle recommends that you use the `orapki` command line tool.
- `ENCRYPTION_WALLET_LOCATION` parameter is being deprecated. The recommended path forward is to use the `WALLET_ROOT` static initialization parameter and the `TDE_CONFIGURATION` dynamic initialization parameter.
- *Oracle Database Advanced Security Guide* for more information on using Transparent Data Encryption
- The description of the `CREATE TABLE "encryption_spec"` for information on using that feature to encrypt table columns
- "[Establishing a Wallet and Encryption Key: Examples](#)"

***affinity\_clauses***

Use the affinity clauses to enable data-dependent routing to provide cache affinity on a RAC database. The affinity logically partitions data across RAC instances so that a distinct subset of data is assigned to each instance. When data is accessed with a sharding key, the request will be routed to the instance that holds the corresponding subset of data. The benefits of affinity are:

- Sharded access for shard-aware applications and transparency for non-sharded applications
- Better cache utilization and reduced block pings

***shutdown\_dispatcher\_clause***

The `SHUTDOWN` clause is relevant only if your system is using the shared server architecture of Oracle Database. It shuts down a dispatcher identified by `dispatcher_name`.

 Note:

Do not confuse this clause with the SQL\*Plus command `SHUTDOWN`, which is used to shut down the entire database.

The `dispatcher_name` must be a string of the form '`Dxxx`', where `xxx` indicates the number of the dispatcher. For a listing of dispatcher names, query the `NAME` column of the `V$DISPATCHER` dynamic performance view.

- If you specify `IMMEDIATE`, then the dispatcher stops accepting new connections immediately and Oracle Database terminates all existing connections through that dispatcher. After all sessions are cleaned up, the dispatcher process shuts down.

- If you do not specify IMMEDIATE, then the dispatcher stops accepting new connections immediately but waits for all its users to disconnect and for all its database links to terminate. Then it shuts down.

### REGISTER Clause

Specify REGISTER to instruct the PMON background process to register the instance with the listeners immediately. If you do not specify this clause, then registration of the instance does not occur until the next time PMON executes the discovery routine. As a result, clients may not be able to access the services for as long as 60 seconds after the listener is started.

#### See Also:

*Oracle Database Concepts* and *Oracle Database Net Services Administrator's Guide* for information on the PMON background process and listeners

### `alter_system_set_clause`

This clause allows you to change parameter values. The `set_parameter_clause` allows you to change the value of a specified initialization parameter. The `USE_STORED_OUTLINES` and `GLOBAL_TOPIC_ENABLED` clauses allow you to change the value of those system parameters.

#### `set_parameter_clause`

You can change the value of many initialization parameters for the current instance, whether you have started the database with a traditional plain-text parameter file (pfile) or with a server parameter file (spfile). *Oracle Database Reference* indicates these parameters in the "Modifiable" category of each parameter description. If you are using a pfile, then the change will persist only for the duration of the instance. However, if you have started the database with an spfile, then you can change the value of the parameter in the spfile itself, so that the new value will occur in subsequent instances.

*Oracle Database Reference* documents all initialization parameters in full. The parameters fall into three categories:

- **Basic parameters:** Database administrators should be familiar with and consider the setting for all of the basic parameters.
- **Functional categories:** *Oracle Database Reference* also lists the initialization parameters by their functional category.
- **Alphabetical listing:** The Table of Contents of *Oracle Database Reference* contains all initialization parameters in alphabetical order.

The ability to change initialization parameter values depends on whether you have started up the database with a traditional plain-text initialization parameter file (pfile) or with a server parameter file (spfile). To determine whether you can change the value of a particular parameter, query the `ISSYS_MODIFIABLE` column of the `V$PARAMETER` dynamic performance view.

If you want to enforce case on parameter values that are string literals, you must enclose them within single quotes.

You can enforce the minimum password length for database user accounts across the entire CDB or individual PDBs by setting the `MANDATORY_USER_PROFILE` parameter in the `init.ora` file.

## Example

This statement sets the MANDATORY\_USER\_PROFILE parameter to the mandatory profile c##cdb\_profile for all the PDBs in the CDB:

```
ALTER SYSTEM SET MANDATORY_USER_PROFILE=c##cdb_profile;
```

Only a common user who has been commonly granted the ALTER SYSTEM privilege or has the SYSDBA administrative privilege can modify the MANDATORY\_USER\_PROFILE in the init.ora file.

### See Also:

- [CREATE PROFILE](#)
- [Managing Security for Oracle Databases](#)

When setting a parameter value, you can specify additional settings as follows:

## COMMENT

The COMMENT clause lets you associate a comment string with this change in the value of the parameter. The comment string cannot contain control characters or a line break. If you also specify SPFILE, then this comment will appear in the parameter file to indicate the most recent change made to this parameter.

## DEFERRED

The DEFERRED keyword sets or modifies the value of the parameter for future sessions that connect to the database. Current sessions retain the old value.

You must specify DEFERRED if the value of the ISSYS\_MODIFIABLE column of V\$PARAMETER for this parameter is DEFERRED. If the value of that column is IMMEDIATE, then the DEFERRED keyword in this clause is optional. If the value of that column is FALSE, then you cannot specify DEFERRED in this ALTER SYSTEM statement.

### See Also:

*Oracle Database Reference* for information on the V\$PARAMETER dynamic performance view

## CONTAINER

You can specify the CONTAINER clause when you set a parameter value in a CDB. A CDB uses an inheritance model for initialization parameters in which PDBs inherit initialization parameter values from the root. In this case, inheritance means that the value of a particular parameter in the root applies to a particular PDB.

A PDB can override the root's setting for some parameters, which means that a PDB has an inheritance property for each initialization parameter that is either true or false. The inheritance property is true for a parameter when the PDB inherits the root's value

for the parameter. The inheritance property is false for a parameter when the PDB does not inherit the root's value for the parameter.

The inheritance property for some parameters must be true. For other parameters, you can change the inheritance property by running the `ALTER SYSTEM SET` statement to set the parameter when the current container is the PDB. If `ISPDB_MODIFIABLE` is `TRUE` for an initialization parameter in the `V$SYSTEM_PARAMETER` view, then the inheritance property can be false for the parameter.

- If you specify `CONTAINER = ALL`, then the parameter setting applies to all containers in the CDB, including the root and all of the PDBs. The current container must be the root.  
Specifying `ALL` sets the inheritance property to true for the parameter in all PDBs.
- If you specify `CONTAINER = CURRENT`, then the parameter setting applies only to the current container. When the current container is the root, the parameter setting applies to the root and to any PDB with an inheritance property of true for the parameter.

If you omit this clause, then `CONTAINER = CURRENT` is the default.

#### See Also:

*Oracle Database Administrator's Guide* for more information on modifying parameters in a CDB

## SCOPE

The `SCOPE` clause lets you specify when the change takes effect. The behavior of this clause depends on whether you are connected to a non-CDB, a CDB root, or a PDB.

**When you issue the `ALTER SYSTEM` statement while connected to a non-CDB or a CDB root,** the scope depends on whether you started up the database using a traditional plain-text parameter file (`pfile`) or server parameter file (`spfile`).

- `MEMORY` indicates that the change is made in memory, takes effect immediately, and persists until the database is shut down. If you started up the database using a parameter file (`pfile`), then this is the only scope you can specify.

Note that `MEMORY` makes changes in memory of all the instances and overwrites values set individually on the instance.

- `SPFILE` indicates that the change is made in the server parameter file. The new setting takes effect when the database is next shut down and started up again. You must specify `SPFILE` when changing the value of a static parameter that is described as not modifiable in *Oracle Database Reference*.

Note that `SPFILE` makes no changes in memory, which means that the instance parameter set individually on the instance takes precedence over global.

- `BOTH` indicates that the change is made in memory and in the server parameter file. The new setting takes effect immediately and persists after the database is shut down and started up again.

Note that `BOTH` makes changes in memory of all the instances and overwrites values set individually on the instance, until the instance is restarted. When the instance is restarted, the spfile is read and then the instance parameter takes precedence.

If a server parameter file was used to start up the database, then `BOTH` is the default. If a parameter file was used to start up the database, then `MEMORY` is the default, as well as the only scope you can specify.

**When you issue the `ALTER SYSTEM` statement while connected to a PDB,** you can modify only initialization parameters for which the `ISPDB_MODIFIABLE` column is `TRUE` in the `V$SYSTEM_PARAMETER` view. The initialization parameter value takes effect only for the PDB. For any initialization parameter that is not set explicitly for a PDB, the PDB inherits the CDB root's parameter value.

- `MEMORY` indicates that the change is made in memory and takes effect immediately in the PDB. The setting reverts to the value set in the CDB root in any of the following cases:
  - An `ALTER SYSTEM SET` statement sets the value of the parameter in the root with `SCOPE` equal to `BOTH` or `MEMORY`, and the PDB is closed and reopened. The parameter value in the PDB is not changed if `SCOPE` is equal to `SPFILE`, and the PDB is closed and reopened.
  - The PDB is closed and reopened.
  - The CDB is shut down and reopened.
- `SPFILE` indicates that the change is made for the PDB and stored persistently. The new setting affects only the PDB and takes effect in either of the following cases:
  - The PDB is closed and reopened.
  - The CDB is shut down and reopened.
- `BOTH` indicates that the change is made in memory, made for the PDB, and stored persistently. The new setting takes effect immediately in the PDB and persists after the PDB is closed and reopened or the CDB is shut down and reopened. The new setting affects only the PDB.

When a PDB is unplugged from a CDB, the values of the initialization parameters that were specified for the PDB with `SCOPE=BOTH` or `SCOPE=SPFILE` are added to the PDB's XML metadata file. These values are restored for the PDB when it is plugged in to a CDB.

#### Note:

Oracle may internally adjust the parameter value passed in `ALTER SYSTEM SET` before it is set in memory or the spfile. For example, if you input a non-prime number when the parameter value should be a prime number, Oracle will adjust the value to the next prime number. You can query the parameter value from parameter views `V$PARAMETER`, `V$SYSTEM_PARAMETER`, and `V$SPPARAMETER`.

#### SID

The `SID` clause lets you specify the SID of the instance where the value will take effect.

- Specify `SID = '*'` if you want Oracle Database to change the value of the parameter for all instances that do not already have an explicit setting for this parameter.

- Specify `SID = 'sid'` if you want Oracle Database to change the value of the parameter only for the instance `sid`. This setting takes precedence over previous and subsequent `ALTER SYSTEM SET` statements that specify `SID = '*'.`

If you do not specify this clause, then:

- If the instance was started up with a pfile (traditional plain-text initialization parameter file), then Oracle Database assumes the SID of the current instance.
- If the instance was started up with an spfile (server parameter file), then Oracle Database assumes `SID = '*'.`

If you specify an instance other than the current instance, then Oracle Database sends a message to that instance to change the parameter value in the memory of that instance.

#### **USE\_STORED\_OUTLINES Clause**

 **Note:**

Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. Refer to *Oracle Database SQL Tuning Guide* for more information about SQL plan management.

`USE_STORED_OUTLINES` is a system parameter, not an initialization parameter. You cannot set it in a pfile or spfile, but you can set it with an `ALTER SYSTEM` statement. This parameter determines whether the optimizer will use stored public outlines to generate execution plans.

- `TRUE` causes the optimizer to use outlines stored in the `DEFAULT` category when compiling requests.
- `FALSE` specifies that the optimizer should not use stored outlines. This is the default.
- `category_name` causes the optimizer to use outlines stored in the `category_name` category when compiling requests.

#### **GLOBAL\_TOPIC\_ENABLED**

`GLOBAL_TOPIC_ENABLED` is a system parameter, not an initialization parameter. You cannot set it in a pfile or spfile, but you can set it with an `ALTER SYSTEM` statement. If `GLOBAL_TOPIC_ENABLED = TRUE` when a queue table is created, altered, or dropped, then the corresponding Lightweight Directory Access Protocol (LDAP) entry is also created, altered or dropped.

The parameter works the same way for the Java Message Service (JMS). If a database has been configured to use LDAP and the `GLOBAL_TOPIC_ENABLED` parameter has been set to `TRUE`, then all JMS queues and topics are automatically registered with the LDAP server when they are created. The administrator can also create aliases to the queues and topics registered in LDAP. Queues and topics that are registered in LDAP can be looked up through JNDI using the name or alias of the queue or topic.

#### **Shared Server Parameters**

When you start your instance, Oracle Database creates shared server processes and dispatcher processes for the shared server architecture based on the values of the `SHARED_SERVERS` and `DISPATCHERS` initialization parameters. You can also set the

SHARED\_SERVERS and DISPATCHERS parameters with ALTER SYSTEM to perform one of the following operations while the instance is running:

- Create additional shared server processes by increasing the minimum number of shared server processes.
- Terminate existing shared server processes after their current calls finish processing.
- Create more dispatcher processes for a specific protocol, up to a maximum across all protocols specified by the initialization parameter MAX\_DISPATCHERS.
- Terminate existing dispatcher processes for a specific protocol after their current user processes disconnect from the instance.

#### See Also:

- *Oracle Real Application Clusters Administration and Deployment Guide* for information on setting parameter values for an individual instance in an Oracle Real Application Clusters environment
- The following examples of using the ALTER SYSTEM statement: "[Changing Licensing Parameters: Examples](#)", "[Enabling Query Rewrite: Example](#)", "[Enabling Resource Limits: Example](#)", "[Shared Server Parameters](#)", and "[Changing Shared Server Settings: Examples](#)"

#### *alter\_system\_reset\_clause*

This clause lets you reset an initialization parameter.

The semantics of this clause are similar to the *set\_parameter\_clause*, except instead of changing the value of an initialization parameter, this clause removes the setting of an initialization parameter. Refer to the [set\\_parameter\\_clause](#) to learn about the parameters you can reset, and for the full semantics of the SCOPE and SID clauses.

#### RELOCATE CLIENT

This clause is valid only if you are using Oracle Flex ASM. You must issue this clause from within an Oracle ASM instance, not from a normal database instance.

Use this clause to relocate the specified client to the least loaded Oracle ASM instance. When you issue this clause, the connection to the client is terminated and the client fails over to the least loaded instance. If the client is currently connected to the least loaded instance, then the connection to the client is terminated and the client fails over to that same instance.

For *client\_id*, specify a string of the following form enclosed in single quotation marks:

*instance\_name:db\_name*

where *instance\_name* is the identifier for the client and *db\_name* is the database name for the client. You can find these values by querying the INSTANCE\_NAME and DB\_NAME columns of the V\$ASM\_CLIENT dynamic performance view.

 **See Also:**

- *Oracle Automatic Storage Management Administrator's Guide* for more information on managing Oracle Flex ASM
- *Oracle Database Reference* for more information on the `V$ASM_CLIENT` dynamic performance view

**cancel\_sql\_clause**

Use this clause to terminate a SQL operation that is consuming excessive resources, including parallel servers. You must provide the session id and the session serial number of the session whose active SQL statement you want to cancel. If the session is idle (no actively running SQL statement), the next SQL statement will be canceled. To avoid the next SQL statement from getting canceled, specify the `sql_id` in the arguments to identify the SQL statement to be canceled.

- `session_id` is required and stands for the session identifier.
- `serial_number` is required and stands for the serial number of the session.
- `instance_id` is optional. If this argument is omitted, the instance id of the current session is used.
- `sql_id` is optional. If this argument is specified, the `sql_id` will be matched with the actively-running SQL statement in the session before terminating the SQL. If the session is executing a SQL statement other than the one specified in the `sql_id` argument, an error is raised.

**Examples****Archiving Redo Logs Manually: Examples**

The following statement manually archives the redo log file group containing the redo log entry with the SCN 9356083:

```
ALTER SYSTEM ARCHIVE LOG CHANGE 9356083;
```

The following statement manually archives the redo log file group containing a member named 'disk1:log6.log' to an archived redo log file in the location 'diska:[arch\$]':

```
ALTER SYSTEM ARCHIVE LOG
  LOGFILE 'disk1:log6.log'
  TO 'diska:[arch$]';
```

**Enabling Query Rewrite: Example**

This statement enables query rewrite in all sessions for all materialized views for which query rewrite has not been explicitly disabled:

```
ALTER SYSTEM SET QUERY_REWRITE_ENABLED = TRUE;
```

**Restricting Sessions: Example**

You might want to restrict sessions if you are performing application maintenance and you want only application developers with `RESTRICTED SESSION` system privilege to log on. To restrict sessions, issue the following statement:

```
ALTER SYSTEM
  ENABLE RESTRICTED SESSION;
```

You can then terminate any existing sessions using the KILL SESSION clause of the ALTER SYSTEM statement.

After performing maintenance on your application, issue the following statement to allow any user with CREATE SESSION system privilege to log on:

```
ALTER SYSTEM
  DISABLE RESTRICTED SESSION;
```

### **Establishing a Wallet and Encryption Key: Examples**

The following statements load information from the server wallet into memory and set the Transparent Data Encryption master key:

```
ALTER SYSTEM SET ENCRYPTION WALLET OPEN IDENTIFIED BY "password";
ALTER SYSTEM SET ENCRYPTION KEY IDENTIFIED BY "password";
```

These statements assume that you have initialized the security module and created a wallet with *password*.

### **Closing a Wallet: Examples**

The following statement removes password-based wallet information from memory:

```
ALTER SYSTEM SET ENCRYPTION WALLET CLOSE IDENTIFIED BY "password";
```

The following statement removes password-based wallet information and auto-login information, if present, from memory:

```
ALTER SYSTEM SET ENCRYPTION WALLET CLOSE;
```

### **Clearing the Shared Pool: Example**

You might want to clear the shared pool before beginning performance analysis. To clear the shared pool, issue the following statement:

```
ALTER SYSTEM FLUSH SHARED_POOL;
```

### **Forcing a Checkpoint: Example**

The following statement forces a checkpoint:

```
ALTER SYSTEM CHECKPOINT;
```

### **Enabling Resource Limits: Example**

This ALTER SYSTEM statement dynamically enables resource limits:

```
ALTER SYSTEM SET RESOURCE_LIMIT = TRUE;
```

### **Changing Shared Server Settings: Examples**

The following statement changes the minimum number of shared server processes to 25:

```
ALTER SYSTEM SET SHARED_SERVERS = 25;
```

If there are currently fewer than 25 shared server processes, then Oracle Database creates more. If there are currently more than 25, then Oracle Database terminates

some of them when they are finished processing their current calls if the load could be managed by the remaining 25.

The following statement dynamically changes the number of dispatcher processes for the TCP/IP protocol to 5 and the number of dispatcher processes for the ipc protocol to 10:

```
ALTER SYSTEM
  SET DISPATCHERS =
    '(INDEX=0) (PROTOCOL=TCP) (DISPATCHERS=5)',
    '(INDEX=1) (PROTOCOL=ipc) (DISPATCHERS=10);
```

If there are currently fewer than 5 dispatcher processes for TCP, then Oracle Database creates new ones. If there are currently more than 5, then Oracle Database terminates some of them after the connected users disconnect.

If there are currently fewer than 10 dispatcher processes for ipc, then Oracle Database creates new ones. If there are currently more than 10, then Oracle Database terminates some of them after the connected users disconnect.

If there are currently existing dispatchers for another protocol, then the preceding statement does not affect the number of dispatchers for that protocol.

### Changing Licensing Parameters: Examples

The following statement dynamically changes the limit on sessions for your instance to 64 and the warning threshold for sessions on your instance to 54:

```
ALTER SYSTEM
  SET LICENSE_MAX_SESSIONS = 64
  LICENSE_SESSIONS_WARNING = 54;
```

If the number of sessions reaches 54, then Oracle Database writes a warning message to the ALERT file for each subsequent session. Also, users with RESTRICTED SESSION system privilege receive warning messages when they begin subsequent sessions.

If the number of sessions reaches 64, then only users with RESTRICTED SESSION system privilege can begin new sessions until the number of sessions falls below 64 again.

The following statement dynamically disables the limit for sessions on your instance. After you issue this statement, Oracle Database no longer limits the number of sessions on your instance.

```
ALTER SYSTEM SET LICENSE_MAX_SESSIONS = 0;
```

The following statement dynamically changes the limit on the number of users in the database to 200. After you issue the preceding statement, Oracle Database prevents the number of users in the database from exceeding 200.

```
ALTER SYSTEM SET LICENSE_MAX_USERS = 200;
```

### Forcing a Log Switch: Example

You might want to force a log switch to drop or rename the current redo log file group or one of its members, because you cannot drop or rename a file while Oracle Database is writing to it. The forced log switch affects only the redo log thread of your instance. The following statement forces a log switch:

```
ALTER SYSTEM SWITCH LOGFILE;
```

### Enabling Distributed Recovery: Example

The following statement enables distributed recovery:

```
ALTER SYSTEM ENABLE DISTRIBUTED RECOVERY;
```

You might want to disable distributed recovery for demonstration or testing purposes. You can disable distributed recovery in both single-process and multiprocess mode with the following statement:

```
ALTER SYSTEM DISABLE DISTRIBUTED RECOVERY;
```

When your demonstration or testing is complete, you can then enable distributed recovery again by issuing an `ALTER SYSTEM` statement with the `ENABLE DISTRIBUTED RECOVERY` clause.

### Terminating a Session: Example

You might want to terminate the session of a user that is holding resources needed by other users. The user receives an error message indicating that the session has been terminated. That user can no longer make calls to the database without beginning a new session. Consider this data from the `V$SESSION` dynamic performance table, when the users `SYS` and `oe` both have open sessions:

```
SELECT sid, serial#, username
  FROM V$SESSION;
```

SID	SERIAL#	USERNAME
29	85	SYS
33	1	
35	8	
39	23	OE
40	1	
...		

The following statement terminates the session of the user `scott` using the `SID` and `SERIAL#` values from `V$SESSION`:

```
ALTER SYSTEM KILL SESSION '39, 23';
```

### Disconnecting a Session: Example

The following statement disconnects user `scott`'s session, using the `SID` and `SERIAL#` values from `V$SESSION`:

```
ALTER SYSTEM DISCONNECT SESSION '13, 8' POST_TRANSACTION;
```

# ALTER TABLE

## Purpose

Use the `ALTER TABLE` statement to alter the definition of a nonpartitioned table, a partitioned table, a table partition, or a table subpartition. For object tables or relational tables with object columns, use `ALTER TABLE` to convert the table to the latest definition of its referenced type after the type has been altered.

 **Note:**

Oracle recommends that you use the ALTER MATERIALIZED VIEW LOG statement, rather than ALTER TABLE, whenever possible for operations on materialized view log tables.

 **See Also:**

- [CREATE TABLE](#) for information on creating tables
- *Oracle Text Reference* for information on ALTER TABLE statements in conjunction with Oracle Text

### Prerequisites

The table must be in your own schema, or you must have ALTER object privilege on the table, or you must have ALTER ANY TABLE system privilege.

#### Additional Prerequisites for Partitioning Operations

If you are not the owner of the table, then you need the DROP ANY TABLE privilege in order to use the `d_table_partition` or `truncate_table_partition` clause.

You must also have space quota in the tablespace in which space is to be acquired in order to use the `add_table_partition`, `modify_table_partition`, `move_table_partition`, and `split_table_partition` clauses.

When a partitioning operation cascades to reference-partitioned child tables, privileges are not required on the reference-partitioned child tables.

When using the `exchange_partition_subpart` clause, if the table data being exchanged contains an identity column and you are not the owner of both tables involved in the exchange, then you must have the ALTER ANY SEQUENCE system privilege.

You cannot partition a non-partitioned table that has an object type.

#### Additional Prerequisites for Constraints and Triggers

To enable a unique or primary key constraint, you must have the privileges necessary to create an index on the table. You need these privileges because Oracle Database creates an index on the columns of the unique or primary key in the schema containing the table.

To enable or disable triggers, the triggers must be in your schema or you must have the ALTER ANY TRIGGER system privilege.

 **See Also:**

[CREATE INDEX](#) for information on the privileges needed to create indexes

### Additional Prerequisites When Using Object Types

To use an object type in a column definition when modifying a table, either that object must belong to the same schema as the table being altered, or you must have either the EXECUTE ANY TYPE system privilege or the EXECUTE object privilege for the object type.

### Additional Prerequisites for Flashback Data Archive Operations

To use the `flashback_archive_clause` to enable historical tracking for the table, you must have the FLASHBACK ARCHIVE object privilege on the flashback data archive that will contain the historical data. To use the `flashback_archive_clause` to disable historical tracking for the table, you must have the FLASHBACK ARCHIVE ADMINISTER system privilege or you must be logged in as SYSDBA.

### Additional Prerequisite for Referring to Editioned Objects

To specify an edition in the `evaluation_edition_clause` or the `unusable_editions_clause`, you must have the USE privilege on the edition.

### Syntax

`alter_table ::=`

#### Note:

You must specify some clause after `table`. None of the clauses after `table` are required, but you must specify at least one of them.

### Groups of ALTER TABLE syntax:

- [\*alter\\_table\\_properties ::=\*](#)
- [\*column\\_clauses ::=\*](#)
- [\*constraint\\_clauses ::=\*](#)
- [\*alter\\_table\\_partitioning ::=\*](#)
- [\*alter\\_table\\_partitionset ::=\*](#)
- [\*alter\\_external\\_table ::=\*](#)
- [\*move\\_table\\_clause ::=\*](#)
- [\*modify\\_to\\_partitioned ::=\*](#)
- [\*modify\\_opaque\\_type ::=\*](#)
- [\*immutable\\_table\\_clauses\*](#)
- [\*blockchain\\_table\\_clauses\*](#)
- [\*duplicated\\_table\\_refresh ::=\*](#)
- [\*enable\\_disable\\_clause ::=\*](#)

After each clause you will find links to its component subclauses.

#### *memoptimize\_read\_clause ::=*

#### *memoptimize\_write\_clause*

### *alter\_table\_properties ::=*

 **Note:**

If you specify the `MODIFY CLUSTERING` clause, then you must specify at least one of the clauses `clustering_when` or `zonemap_clause`.

### Semantics

Many clauses of the ALTER TABLE statement have the same functionality they have in a CREATE TABLE statement. For more information on such clauses, see [CREATE TABLE](#).

#### Note:

Operations performed by the ALTER TABLE statement can cause Oracle Database to invalidate procedures and stored functions that access the table. For information on how and when the database invalidates such objects, see *Oracle Database Development Guide*.

### IF EXISTS

Specify IF EXISTS to alter an existing table.

Specifying IF NOT EXISTS with ALTER VIEW results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

***schema***

Specify the schema containing the table. If you omit *schema*, then Oracle Database assumes the table is in your own schema.

***table***

Specify the name of the table to be altered.

**Note:**

If you alter a table that is a master table for one or more materialized views, then Oracle Database marks the materialized views `INVALID`. Invalid materialized views cannot be used by query rewrite and cannot be refreshed. For information on revalidating a materialized view, see [ALTER MATERIALIZED VIEW](#).

**See Also:**

[Oracle Database Data Warehousing Guide](#) for more information on materialized views in general

**Restrictions on Altering Temporary Tables**

You can modify, drop columns from, or rename a temporary table. However, for a temporary table you cannot:

- Add columns of nested table type. You can add columns of other types.
- Specify referential integrity (foreign key) constraints for an added or modified column.
- Specify the following clauses of the *LOB storage clause* for an added or modified LOB column: `TABLESPACE`, `storage_clause`, `logging_clause`, `allocate_extent_clause`, or `deallocate_unused_clause`.
- Specify the `physical_attributes_clause`, `nested_table_col_properties`, `parallel_clause`, `allocate_extent_clause`, `deallocate_unused_clause`, or any of the index-organized table clauses.
- Exchange partitions between a partition and a temporary table.
- Specify the `logging_clause`.
- Specify `MOVE`.
- Add an `INVISIBLE` column or modify an existing column to be `INVISIBLE`.

**Restrictions on Altering External Tables**

You can add, drop, or modify the columns of an external table. However, for an external table you cannot:

- Add a LONG, LOB, or object type column or change the data type of an external table column to any of these data types.
- Modify the storage parameters of an external table.
- Specify the *logging clause*.
- Specify MOVE.
- Add an INVISIBLE column or modify an existing column to be INVISIBLE.

#### ***memoptimize\_read\_clause***

Use this clause to improve the performance high frequency data query operations. The MEMOPTIMIZE\_POOL\_SIZE initialization parameter controls the size of the memoptimize pool. Note that the feature uses additional memory from the SGA.

- You must specify this clause as a top-level attribute of the table, it cannot be specified at the partition or subpartition level.
- You must explicitly enable the table for MEMOPTIMIZE FOR READ before you can read data from the table.
- You must explicitly disable the table for NO MEMOPTIMIZE FOR READ when you no longer need it.

#### ***memoptimize\_write\_clause***

Use this clause to enable fast ingest. Fast ingest optimizes the processing of high frequency single row data inserts from Internet of Things (IoT) applications by using a large buffering pool to store the inserts before writing them to disk.

#### **Restrictions**

Blockchain and immutable tables do not support the *memoptimize\_write\_clause*.

#### ***alter\_table\_properties***

Use the *alter\_table\_clauses* to modify a database table.

#### ***physical\_attributes\_clause***

The *physical\_attributes\_clause* lets you change the value of the PCTFREE, PCTUSED, and INITTRANS parameters and storage characteristics. Refer to [physical\\_attributes\\_clause](#) and [storage\\_clause](#) for a full description of these parameters and characteristics.

#### **Restrictions on Altering Table Physical Attributes**

Altering physical attributes is subject to the following restrictions:

- You cannot specify the PCTUSED parameter for the index segment of an index-organized table.
- If you attempt to alter the storage attributes of tables in locally managed tablespaces, then Oracle Database raises an error. However, if some segments of a partitioned table reside in a locally managed tablespace and other segments reside in a dictionary-managed tablespace, then the database alters the storage attributes of the segments in the dictionary-managed tablespace but does not alter the attributes of the segments in the locally managed tablespace, and does not raise an error.

- For segments with automatic segment-space management, the database ignores attempts to change the PCTUSED setting. If you alter the PCTFREE setting, then you must subsequently run the DBMS\_REPAIR.SEGMENT\_FIX\_STATUS procedure to implement the new setting on blocks already allocated to the segment.

### Cautions on Altering Tables Physical Attributes

The values you specify in this clause affect the table as follows:

- For a nonpartitioned table, the values you specify override any values specified for the table at create time.
- For a range-, list-, or hash-partitioned table, the values you specify are the default values for the table and the actual values for every existing partition, overriding any values already set for the partitions. To change default table attributes without overriding existing partition values, use the `modify_table_defaultAttrs` clause.
- For a composite-partitioned table, the values you specify are the default values for the table and all partitions of the table and the actual values for all subpartitions of the table, overriding any values already set for the subpartitions. To change default partition attributes without overriding existing subpartition values, use the `modify_table_defaultAttrs` clause with the `FOR PARTITION` clause.

### *logging\_clause*

Use the `logging_clause` to change the logging attribute of the table. The `logging_clause` specifies whether subsequent ALTER TABLE ... MOVE and ALTER TABLE ... SPLIT operations will be logged or not logged.

When used with the `modify_table_defaultAttrs` clause, this clause affects the logging attribute of a partitioned table.

#### See Also:

- [logging\\_clause](#) for a full description of this clause
- [Oracle Database VLDB and Partitioning Guide](#) for more information about the `logging_clause` and parallel DML

### *table\_compression*

The `table_compression` clause is valid only for heap-organized tables. Use this clause to instruct Oracle Database whether to compress data segments to reduce disk and memory use. Refer to the CREATE TABLE [table\\_compression](#) for the full semantics of this clause and for information on creating objects with table compression.

#### Note:

The first time a table is altered in such a way that compressed data will be added, all bitmap indexes and bitmap index partitions on that table must be marked UNUSABLE.

### *inmemory\_table\_clause*

Use this clause to enable or disable a table or table column for the In-Memory Column Store (IM column store), or to change the In-Memory attributes for a table or table column.

- Specify `INMEMORY` to enable a table for the IM column store, or to change the *inmemory\_attributes* for a table that is already enabled for the IM column store.
- Specify `NO INMEMORY` to disable a table for the IM column store.
- Specify the *inmemory\_column\_clause* to enable or disable a table column for the IM column store, or to change the *inmemory\_memcompress* setting for a table column. If you specify this clause when the table or partition is disabled for the IM column store, then the column settings will take effect when the table or partition is subsequently enabled for the IM column store. Regardless of whether the table or partition is enabled or disabled for the IM column store, when you specify `NO INMEMORY` for a column, any previously specified *inmemory\_memcompress* setting for the column is lost. Refer to the *inmemory\_column\_clause* of `CREATE TABLE` for the full semantics of this clause.

This *inmemory\_table\_clause* has the same semantics as the *inmemory\_table\_clause* of `CREATE TABLE`, with the following additions:

- When you specify the *inmemory\_memcompress* clause to change the data compression method for a table that is already enabled for the IM column store, any columns that were previously assigned a specific data compression method will retain that data compression method. Refer to the *inmemory\_memcompress* clause of `CREATE TABLE` for more information on this clause.
- When you specify the *inmemory\_distribute* clause, if you omit one subclause, then its setting remains unchanged. That is, if you specify only the `AUTO` or `BY` clause, then the `FOR SERVICE` setting for the table remains unchanged, and if you specify only the `FOR SERVICE` clause, then the `AUTO` or `BY` setting for the table remains unchanged. If you omit both subclauses and specify only the `DISTRIBUTE` keyword, then the table is assigned the `DISTRIBUTE AUTO` setting and its `FOR SERVICE` setting remains unchanged. Refer to the *inmemory\_distribute* clause of `CREATE TABLE` for more information on this clause.
- When you specify `NO INMEMORY` to disable a partitioned or nonpartitioned table for the IM column store, any column-level In-Memory settings are lost. If you subsequently enable the table for the IM column store, then all columns will use the In-Memory settings for the table, unless you specify otherwise when enabling the table.
- When you specify `NO INMEMORY` to disable a partition for the IM column store, the column-level In-Memory settings are retained, even if all partitions in the table are disabled. If you subsequently enable the table or a partition for the IM column store, then the column-level In-Memory settings will go into effect, unless you specify otherwise when enabling the table or partition.
- If a table is currently populated in the IM column store and you change any *inmemory\_attribute* of the table other than `PRIORITY`, then the database evicts the table from the IM column store. The repopulation behavior depends on the `PRIORITY` setting.

### *inmemory\_clause*

Use this clause to enable or disable a table partition for the IM column store, or to change the In-Memory parameters for a table partition. This clause has the same semantics in `CREATE TABLE` and `ALTER TABLE`. Refer to the *inmemory\_clause* in the documentation on `CREATE TABLE` for the full semantics of this clause.

You can specify IMMEMORY on non-partitioned tables using the ORACLE\_HIVE, ORACLE\_HDFS, and ORACLE\_BIGDATA driver types.

For more details on the In-Memory column architecture see Oracle Database In-Memory Guide

#### Restriction

If a segment on disk is 64 KB or less, then it is not populated in the IM column store. Therefore, some small database objects that were enabled for the IM column store might not be populated.

#### *ilm\_clause*

Use this clause to add, delete, enable, or disable Automatic Data Optimization policies for the table.

#### ADD POLICY

Specify this clause to add a policy for the table.

Use *ilm\_policy\_clause* to specify the policy. Refer to the *ilm\_policy\_clause* for the full semantics of this clause

Oracle Database assigns a name to the policy of the form `Pn` where `n` is an integer value

#### { DELETE | ENABLE | DISABLE } POLICY

Specify these clauses to delete a policy for the table, enable a policy for the table, or disable a policy for the table, respectively.

For *ilm\_policy\_name*, specify the name of the policy. You can view policy names by querying the `POLICY_NAME` column of the `DBA_IILMPOLICIES` view.

#### { DELETE\_ALL, ENABLE\_ALL, DISABLE\_ALL }

Specify these clauses to delete all policies for the table, enable all policies for the table, or disable all policies for the table, respectively.

#### See Also:

*Oracle Database VLDB and Partitioning Guide* for more information on managing policies for Automatic Data Optimization

#### *ilm\_policy\_clause*

This clause lets you specify an Automatic Data Optimization policy. You can use the *ilm\_compression\_policy* clause to specify a compression policy, the *ilm\_tiering\_policy* clause to specify a storage tiering policy, or the *ilm\_inmemory\_policy* clause to specify an In-Memory Column Store policy.

#### *ilm\_compression\_policy*

Use this clause to specify a compression policy. This type of policy instructs the database to compress data when a specified condition is met. Use the SEGMENT, GROUP, or ROW clause to specify a segment-level, group-level, or row-level compression policy.

**table\_compression**

Use the *table\_compression* clause to specify the compression type. This clause applies to segment-level and group-level compression policies.

You must specify a compression type that is higher than the current compression type. The order of compression types from lowest to highest is:

```
NOCOMPRESS  
ROW STORE COMPRESS BASIC  
ROW STORE COMPRESS ADVANCED  
COLUMN STORE COMPRESS FOR QUERY LOW  
COLUMN STORE COMPRESS FOR QUERY HIGH  
COLUMN STORE COMPRESS FOR ARCHIVE LOW  
COLUMN STORE COMPRESS FOR ARCHIVE HIGH
```

Refer to [table\\_compression](#) for the full semantics of this clause.

**SEGMENT**

Specify SEGMENT to create a segment-level compression policy. This type of policy instructs the database to compress table segments when the condition specified in the AFTER clause is met or when the PL/SQL function specified in the ON clause returns TRUE.

Note that you cannot modify a segment using ALTER TABLE.

**GROUP**

Specify GROUP to create a group-level compression policy. This type of policy instructs the database to compress the table and its dependent objects, such as indexes and SecureFiles LOBs, when the condition specified in the AFTER clause is met or when the PL/SQL function specified in the ON clause returns TRUE.

**ROW**

Specify ROW to create a row-level compression policy. This type of policy instructs the database to compress database blocks in which all the rows have not been modified for a specified period of time. When creating a row-level policy, you must specify ROW STORE COMPRESS ADVANCED or COLUMN STORE COMPRESS FOR QUERY compression, and you must specify AFTER *ilm\_time\_period* OF NO MODIFICATION. Refer to [table\\_compression](#) for the full semantics of the ROW STORE COMPRESS ADVANCED and COLUMN STORE COMPRESS FOR QUERY clauses.

**AFTER**

Use this clause to describe the condition that must be met in order for the policy to take effect. The condition consists of a length of time, specified with the *ilm\_time\_period* clause, and one of the following condition types:

- OF NO ACCESS: The policy will take effect after table has not been accessed for the specified length of time.
- OF NO MODIFICATION: The policy will take effect after table has not been modified for the specified length of time.
- OF CREATION: The policy will take effect when the specified length of time has passed since table was created.

***ilm\_time\_period***

Specify a length of time in days, months, or years after which the condition must be met. For *integer*, specify a positive integer. The DAY and DAYS keywords can be used interchangeably and are provided for semantic clarity. This is also the case for the MONTH and MONTHS keywords, and the YEAR and YEARS keywords.

## ON

Use this clause to specify a PL/SQL function that returns a boolean value. For *function\_name*, specify the name of the function. The policy will take effect when the function returns TRUE.

### Note:

The ON *function\_name* clause is not supported for tablespaces.

## *ilm\_tiering\_policy*

Use this clause to specify a storage tiering policy. This type of policy instructs the database to migrate data to a specified tablespace, either when a specified condition is met or when data usage reaches a specified limit. Use the SEGMENT or GROUP clause to specify a segment-level or group-level policy. You can migrate data to a read/write tablespace or a read-only tablespace.

### TIER TO *tablespace*

Use this clause to migrate data to a read/write *tablespace*.

- If you specify the ON *function* clause, then data will be migrated when function returns TRUE. Refer to the ON clause for the full semantics of this clause.
- If you omit the ON *function* clause, then data will be migrated when data usage of the tablespace quota reaches the percentage defined by TBS\_PERCENT\_USED. The database will make a best effort to migrate enough data so that the amount of free space within the tablespace quota reaches the percentage defined by TBS\_PERCENT\_FREE. Refer to Oracle Database PL/SQL Packages and Types Reference for more information on TBS\_PERCENT\_USED and TBS\_PERCENT\_FREE, which are constants in the DBMS\_ILM\_ADMIN package.

### TIER TO *tablespace* READ ONLY

Use this clause to migrate data to a read-only tablespace. When migrating data to the tablespace, the database temporarily places the tablespace in read/write mode, migrates the data, and then places the tablespace back in read-only mode.

- If you specify the AFTER clause, then data will be migrated when the specified condition is met. Refer to the AFTER clause for the full semantics of this clause
- If you specify the ON *function* clause, then data will be migrated when function returns TRUE. Refer to the ON clause for the full semantics of this clause.

### SEGMENT | GROUP

Specify SEGMENT to create a segment-level storage tiering policy. This type of policy instructs the database to migrate table segments to *tablespace*. Specify GROUP to create a group-level storage tiering policy. This type of policy instructs the database to

migrate the table and its dependent objects, such as indexes and SecureFiles LOBs, to tablespace. The default is SEGMENT.

 **Note:**

The `ON function_name` clause is not supported for tablespaces.

### *ilm\_inmemory\_policy*

Use this clause to specify an In-Memory Column Store (IM column store) policy. This type of policy instructs the database to enable or disable the table for the IM column store, or to change the compression method for the table in the IM column store, when a specified condition is met.

#### **SET INMEMORY**

Use this clause to enable the table for the IM column store when the specified condition is met. You can optionally use the `inmemory_attributes` clause to specify how table data will be stored in the IM column store. Refer to [inmemory\\_attributes](#) for the full semantics of this clause.

#### **MODIFY INMEMORY**

Use this clause to change the compression method for table data stored in the IM column store when the specified condition is met. The table must be enabled for the IM column store.

You must specify a compression method that is higher than the current compression method. The order of compression methods from lowest to highest is:

NO INMEMORY  
MEMCOMPRESS FOR DML  
MEMCOMPRESS FOR QUERY LOW  
MEMCOMPRESS FOR QUERY HIGH  
MEMCOMPRESS FOR CAPACITY LOW  
MEMCOMPRESS FOR CAPACITY HIGH

Refer to [inmemory\\_memcompress](#) for the full semantics of this clause.

#### **NO INMEMORY**

Use this clause to disable the table for the IM column store when the specified condition is met.

#### **SEGMENT**

The `SEGMENT` keyword is optional and is provided for semantic clarity. IM column store policies are always segment-level policies.

#### **AFTER | ON**

The `AFTER` and `ON` clauses enable you to specify the condition that must be met in order for the IM column store policy to take effect:

- If you specify the `AFTER` clause, then the policy will take effect when the specified condition is met. Refer to the [AFTER](#) clause for the full semantics of this clause

- If you specify the `ON` function clause, then the policy will take effect when function returns `TRUE`. Refer to the `ON` clause for the full semantics of this clause.

 **Note:**

The `ON` `function_name` clause is not supported for tablespaces.

 **See Also:**

*Oracle Database In-Memory Guide* for more information on using Automatic Data Optimization policies with the IM column store

### *supplemental\_table\_logging*

Use the `supplemental_table_logging` clause to add or drop a redo log group or one or more supplementally logged columns in a redo log group.

- In the `ADD` clause, use `supplemental_log_grp_clause` to create named supplemental log group. Use the `supplemental_id_key_clause` to create a system-generated log group.
- On the `DROP` clause, use `GROUP log_group` syntax to drop a named supplemental log group and use the `supplemental_id_key_clause` to drop a system-generated log group.

The `supplemental_log_grp_clause` and the `supplemental_id_key_clause` have the same semantics in `CREATE TABLE` and `ALTER TABLE` statements. For full information on these clauses, refer to [supplemental\\_log\\_grp\\_clause](#) and [supplemental\\_id\\_key\\_clause](#) in the documentation on `CREATE TABLE`.

 **See Also:**

*Oracle Data Guard Concepts and Administration* for information on supplemental redo log groups

### *allocate\_extent\_clause*

Use the `allocate_extent_clause` to explicitly allocate a new extent for the table, the partition or subpartition, the overflow data segment, the LOB data segment, or the LOB index.

#### **Restriction on Allocating Table Extents**

You cannot allocate an extent for a temporary table or for a range- or composite-partitioned table.

**See Also:**

[allocate\\_extent\\_clause](#) for a full description of this clause and "Allocating Extents: Example"

***deallocate\_unused\_clause***

***deallocate\_unused\_clause*** Use the ***deallocate\_unused\_clause*** to explicitly deallocate unused space at the end of the table, partition or subpartition, overflow data segment, LOB data segment, or LOB index and make the space available for other segments in the tablespace.

**See Also:**

[deallocate\\_unused\\_clause](#) for a full description of this clause and "Deallocating Unused Space: Example"

***rename\_job\_storage\_clause***

Specify this clause to rename a LOB data segment internally.

Specify the following arguments:

- *table\_name*
- *column\_name* can be of type BLOB or CLOB
- *old\_segment\_name* can query all\_lobs, all\_lob\_partition or all\_lob\_subpartition
- PARTITION or SUBPARTITION for partitioned tables, NULL for non-partitioned tables
- *new\_segment\_name*. The rename ensures that the new segment name is unique within the database. A name conflict results in an error.

**CACHE | NOCACHE**

The CACHE and NOCACHE clauses have the same semantics in CREATE TABLE and ALTER TABLE statements. For complete information on these clauses, refer to "[CACHE | NOCACHE | CACHE READS](#)" in the documentation on CREATE TABLE. If you omit both of these clauses in an ALTER TABLE statement, then the existing value is unchanged.

***result\_cache\_clause***

The ***result\_cache\_clause*** clause has the same semantics in CREATE TABLE and ALTER TABLE statements. For complete information on this clause, refer to "[result\\_cache\\_clause](#)" in the documentation on CREATE TABLE. If you omit this clause in an ALTER TABLE statement, then the existing setting is unchanged.

**Examples**

```
ALTER TABLE employee RESULT_CACHE (MODE DEFAULT)
    ALTER TABLE employee RESULT_CACHE (STANDBY ENABLE)
    ALTER TABLE employee RESULT_CACHE (MODE DEFAULT, STANDBY ENABLE)
    ALTER TABLE employee RESULT_CACHE (STANDBY ENABLE, MODE FORCE)
```

### ***upgrade\_table\_clause***

The *upgrade\_table\_clause* is relevant for object tables and for relational tables with object columns. It lets you instruct Oracle Database to convert the metadata of the target table to conform with the latest version of each referenced type. If table is already valid, then the table metadata remains unchanged.

#### **Restriction on Upgrading Object Tables and Columns**

Within this clause, you cannot specify *object\_type\_col\_properties* as a clause of *column\_properties*.

#### **INCLUDING DATA**

Specify **INCLUDING DATA** if you want Oracle Database to convert the data in the table to the latest type version format. You can define the storage for any new column while upgrading the table by using the *column\_properties* and the *LOB\_partition\_storage*. This is the default.

You can convert data in the table at the time you upgrade the type by specifying **CASCADE INCLUDING TABLE DATA** in the *dependent\_handling\_clause* of the **ALTER TYPE** statement. See *Oracle Database PL/SQL Language Reference* for information on this clause. For information on whether a table contains data based on an older type version, refer to the **DATA\_UPGRADED** column of the **USER\_TAB\_COLUMNS** data dictionary view.

#### **NOT INCLUDING DATA**

Specify **NOT INCLUDING DATA** if you want Oracle Database to leave column data unchanged.

#### **Restriction on NOT INCLUDING DATA**

You cannot specify **NOT INCLUDING DATA** if the table contains columns in Oracle8 release 8.0.x image format. To determine whether the table contains such columns, refer to the **V80\_FMT\_IMAGE** column of the **USER\_TAB\_COLUMNS** data dictionary view.

#### **See Also:**

- [Oracle Database Reference](#) for information on the data dictionary views
- [ALTER TYPE](#) for information on converting dependent table data when modifying a type upon which the table depends

### ***records\_per\_block\_clause***

The *records\_per\_block\_clause* lets you specify whether Oracle Database restricts the number of records that can be stored in a block. This clause ensures that any bitmap indexes subsequently created on the table will be as compressed as possible.

#### **Restrictions on Records in a Block**

The *record\_per\_block\_clause* is subject to the following restrictions:

- You cannot specify either MINIMIZE or NOMINIMIZE if a bitmap index has already been defined on table. You must first drop the bitmap index.
- You cannot specify this clause for an index-organized table or a nested table.

### MINIMIZE

Specify MINIMIZE to instruct Oracle Database to calculate the largest number of records in any block in the table and to limit future inserts so that no block can contain more than that number of records.

Oracle recommends that a representative set of data already exist in the table before you specify MINIMIZE. If you are using table compression (see [table\\_compression](#) ), then a representative set of compressed data should already exist in the table.

### Restriction on MINIMIZE

You cannot specify MINIMIZE for an empty table.

### NOMINIMIZE

Specify NOMINIMIZE to disable the MINIMIZE feature. This is the default.

#### *row\_movement\_clause*

You cannot disable row movement in a reference-partitioned table unless row movement is also disabled in the parent table. Otherwise, this clause has the same semantics in CREATE TABLE and ALTER TABLE statements. For complete information on these clauses, refer to [row\\_movement\\_clause](#) in the documentation on CREATE TABLE.

#### *logical\_replication\_clause*

You can perform partial database replication for users such as Oracle GoldenGate, and reduce the supplemental logging overhead of uninteresting tables in interesting schema where supplemental logging is enabled. For full semantics see CREATE TABLE [logical\\_replication\\_clause::=](#).

#### *flashback\_archive\_clause*

You must have the FLASHBACK ARCHIVE object privilege on the specified flashback archive to specify this clause. Use this clause to enable or disable historical tracking for the table.

- Specify FLASHBACK ARCHIVE to enable tracking for the table. You can specify *flashback\_archive* to designate a particular flashback archive for this table. The flashback archive you specify must already exist.

If you omit the archive name, then the database uses the default flashback archive designated for the system. If no default flashback archive has been designated for the system, then you must specify *flashback\_archive*.

You cannot specify FLASHBACK ARCHIVE to change the flashback archive for this table. Instead you must first issue an ALTER TABLE statement with the NO FLASHBACK ARCHIVE clause and then issue an ALTER TABLE statement with the FLASHBACK ARCHIVE clause.

- Specify NO FLASHBACK ARCHIVE to disable tracking for the table.

 **See Also:**

The CREATE TABLE [flashback\\_archive\\_clause](#) for information on creating a table with tracking enabled and [CREATE FLASHBACK ARCHIVE](#) for information on creating default flashback archives

## RENAME TO

Use the RENAME clause to rename *table* to *new\_table\_name*.

Using this clause invalidates any dependent materialized views. For more information on materialized views, see [CREATE MATERIALIZED VIEW](#) and *Oracle Database Data Warehousing Guide*.

If a domain index is defined on the table, then the database invokes the ODCIIndexAlter() method with the RENAME option. This operation establishes correspondence between the indextype metadata and the base table.

### Restriction on Renaming Tables

You cannot rename a sharded table or a duplicated table.

### *shrink\_clause*

The shrink clause lets you manually shrink space in a table, index-organized table or its overflow segment, index, partition, subpartition, LOB segment, materialized view, or materialized view log. This clause is valid only for segments in tablespaces with automatic segment management. By default, Oracle Database compacts the segment, adjusts the high water mark, and releases the recuperated space immediately.

Compacting the segment requires row movement. Therefore, you must enable row movement for the object you want to shrink before specifying this clause. Further, if your application has any rowid-based triggers, you should disable them before issuing this clause.

With release 21c, you can use the *shrink\_clause* on SecureFile LOB segments. There are two ways to invoke the *shrink\_clause*:

1. This command targets a specific LOB column and all its partitions.

```
ALTER TABLE <table_name> MODIFY LOB <lob_column> SHRINK SPACE
```

2. This command cascades the shrink operation for all the LOB columns and its partitions for the given table .

```
ALTER TABLE <table_name> SHRINK SPACE CASCADE
```

### Restrictions:

The *shrink\_clause* is not supported on IOT partition tables.

 **Note:**

Do not attempt to enable row movement for an index-organized table before specifying the *shrink\_clause*. The `ROWID` of an index-organized table is its primary key, which never changes. Therefore, row movement is neither relevant nor valid for such tables.

## COMPACT

If you specify `COMPACT`, then Oracle Database only defragments the segment space and compacts the table rows for subsequent release. The database does not readjust the high water mark and does not release the space immediately. You must issue another `ALTER TABLE ... SHRINK SPACE` statement later to complete the operation. This clause is useful if you want to accomplish the shrink operation in two shorter steps rather than one longer step.

For an index or index-organized table, specifying `ALTER [INDEX | TABLE] ... SHRINK SPACE COMPACT` is equivalent to specifying `ALTER [INDEX | TABLE] ... COALESCE`. The *shrink\_clause* can be cascaded (refer to the `CASCADE` clause, which follows) and compacts the segment more densely than does a coalesce operation, which can improve performance. However, if you do not want to release the unused space, then you can use the appropriate `COALESCE` clause.

## CASCADE

If you specify `CASCADE`, then Oracle Database performs the same operations on all dependent objects of *table*, including secondary indexes on index-organized tables.

### Restrictions on the *shrink\_clause*

The *shrink\_clause* is subject to the following restrictions:

- You cannot combine this clause with any other clauses in the same `ALTER TABLE` statement.  
You cannot specify this clause for a cluster, a clustered table, or any object with a `LONG` column.
- Segment shrink is not supported for tables with function-based indexes, domain indexes, or bitmap join indexes.
- This clause does not shrink mapping tables of index-organized tables, even if you specify `CASCADE`.
- You can specify this clause for a table with Advanced Row Compression enabled (`ROW STORE COMPRESS ADVANCED`). You cannot specify this clause for a table with any other type of table compression enabled.
- You cannot shrink a table that is the master table of an `ON COMMIT` materialized view. Rowid materialized views must be rebuilt after the shrink operation.

## READ ONLY | READ WRITE

Specify `READ ONLY` to put the table in read-only mode. When the table is in `READ ONLY` mode, you cannot issue any DML statements that affect the table or any `SELECT ... FOR UPDATE` statements. You can issue DDL statements as long as they do not modify any table data. Operations on indexes associated with the table are allowed when the table is in `READ ONLY`

mode. See *Oracle Database Administrator's Guide* for the complete list of operations that are allowed and disallowed on read-only tables.

Specify `READ WRITE` to return a read-only table to read/write mode.

#### **REKEY *encryption\_spec***

Use the `REKEY` clause to generate a new encryption key or to switch between different algorithms. This operation returns only after all encrypted columns in the table, including LOB columns, have been reencrypted.

#### **DEFAULT COLLATION**

This clause lets you change the default collation for the table. For `collation_name`, specify a valid named collation or pseudo-collation.

The new default collation for the table is assigned to columns of a character data type that are subsequently added to the table with an `ALTER TABLE ADD` statement or modified from a non-character data type with an `ALTER TABLE MODIFY` statement. The collations for existing columns in the table are not changed. Refer to the **DEFAULT COLLATION** clause of `CREATE TABLE` for the full semantics of this clause.

#### **[NO] ROW ARCHIVAL**

Specify this clause to enable or disable `table` for row archival.

- Specify `ROW ARCHIVAL` to enable `table` for row archival. A hidden column `ORA_ARCHIVE_STATE` is created in the table. If the table is already populated with data, then the value of `ORA_ARCHIVE_STATE` is set to 0 for each existing row in the table. You can subsequently use the `UPDATE` statement to set the value of `ORA_ARCHIVE_STATE` to 1 for rows you want to archive.
- Specify `NO ROW ARCHIVAL` to disable `table` for row archival. The hidden column `ORA_ARCHIVE_STATE` is dropped from the table.

#### **Restrictions on [NO] ROW ARCHIVAL**

The following restrictions apply to this clause:

- You cannot specify the `ROW ARCHIVAL` clause for a table that already contains a column named `ORA_ARCHIVE_STATE`.
- You cannot specify the `NO ROW ARCHIVAL` clause for tables owned by `SYS`.

#### **See Also:**

- The `CREATE TABLE ROW ARCHIVAL` clause for the full semantics of this clause
- *Oracle Database VLDB and Partitioning Guide* for more information on In-Database Archiving

#### ***attribute\_clustering\_clause***

Use the `ADD attribute_clustering_clause` to enable the table for attribute clustering. The `attribute_clustering_clause` has the same semantics for `ALTER TABLE` and

CREATE TABLE. Refer to the [attribute\\_clustering\\_clause](#) in the documentation on CREATE TABLE.

## MODIFY CLUSTERING

Use this clause to allow or disallow attribute clustering for the table during direct-path insert operations or data movement operations. The table must be enabled for attribute clustering. The [clustering\\_when\\_clause](#) and the [zonemap\\_clause](#) have the same semantics for ALTER TABLE and CREATE TABLE. Refer to the [clustering\\_when\\_clause](#) and the [zonemap\\_clause](#) in the documentation on CREATE TABLE.

## DROP CLUSTERING

Use this clause to disable the table for attribute clustering.

If a zone map on the table was created using the WITH MATERIALIZED ZONEMAP clause of CREATE TABLE or ALTER TABLE, then the zone map will be dropped. If a zone map on the table was created using the CREATE MATERIALIZED ZONEMAP statement, then the zone map will not be dropped.

## FOR STAGING

You can change the staging property of an existing table with ALTER TABLE t FOR STAGING. The staging table t now has all the characteristics of a staging table created with CREATE TABLE t FOR STAGING.

Refer to CREATE TABLE clause for the full semantics of staging tables: [FOR STAGING](#)

## ALTER TABLE t NOT FOR STAGING

You can change a staging table with ALTER TABLE t NOT FOR STAGING. This means:

- You can enable compression explicitly on the table, its partitions, and future data loads.
- You can gather statistics on the table explicitly or by using an statistics gathering application.
- When you drop the table, it can be put in the recyclebin.

### ***alter\_iot\_clauses***

#### ***index\_org\_table\_clause***

This clause lets you alter some of the characteristics of an existing index-organized table. Index-organized tables keep data sorted on the primary key and are therefore best suited for primary-key-based access and manipulation. See [index\\_org\\_table\\_clause](#) in the context of CREATE TABLE.

#### See Also:

["Modifying Index-Organized Tables: Examples"](#)

### ***prefix\_compression***

Use the [prefix\\_compression](#) clause to enable prefix compression for the table. Specify COMPRESS to instruct Oracle Database to combine the primary key index blocks of the index-

organized table where possible to free blocks for reuse. You can specify this clause with the `parallel_clause`. Specify `NOCOMPRESS` to disable prefix compression for the table.

#### ***iot\_advanced\_compression***

Specify `iot_advanced_compression` to compress the indexes of index organized tables (IOTs) and table partitions in order to reduce the storage footprint of IOTs.

You can enable advanced low index compression for all IOTs on specific partitions of a table, and leave other partitions uncompressed.

#### **PCTTHRESHOLD *integer***

Refer to "[PCTTHRESHOLD \*integer\*](#)" in the documentation on CREATE TABLE.

#### **INCLUDING *column\_name***

Refer to "[INCLUDING \*column\\_name\*](#)" in the documentation on CREATE TABLE.

#### ***overflow\_attributes***

The `overflow_attributes` let you specify the overflow data segment physical storage and logging attributes to be modified for the index-organized table. Parameter values specified in this clause apply only to the overflow data segment.

#### See Also:

[CREATE TABLE](#)

#### ***add\_overflow\_clause***

The `add_overflow_clause` lets you add an overflow data segment to the specified index-organized table. You can also use this clause to explicitly allocate an extent to or deallocate unused space from an existing overflow segment.

Use the `STORE IN tablespace` clause to specify tablespace storage for the entire overflow segment. Use the `PARTITION` clause to specify tablespace storage for the segment by partition.

For a partitioned index-organized table:

- If you do not specify `PARTITION`, then Oracle Database automatically allocates an overflow segment for each partition. The physical attributes of these segments are inherited from the table level.
- If you want to specify separate physical attributes for one or more partitions, then you must specify such attributes for every partition in the table. You need not specify the name of the partitions, but you must specify their attributes in the order in which they were created.

You can find the order of the partitions by querying the `PARTITION_NAME` and `PARTITION_POSITION` columns of the `USER_IND_PARTITIONS` view.

If you do not specify TABLESPACE for a particular partition, then the database uses the tablespace specified for the table. If you do not specify TABLESPACE at the table level, then the database uses the tablespace of the partition primary key index segment.

### Restrictions on Overflow Attributes

Within the *segment\_attributes\_clause*:

- You cannot specify the OPTIMAL parameter of the *physical\_attributes\_clause*.
- You cannot specify tablespace storage for the overflow segment using this clause. For a nonpartitioned table, you can use ALTER TABLE ... MOVE ... OVERFLOW to move the segment to a different tablespace. For a partitioned table, use ALTER TABLE ... MODIFY DEFAULT ATTRIBUTES ... OVERFLOW to change the default tablespace of the overflow segment.

Additional restrictions apply if *table* is in a locally managed tablespace, because in such tablespaces several segment attributes are managed automatically by the database.

#### See Also:

[allocate\\_extent\\_clause](#) and [deallocate\\_unused\\_clause](#) for full descriptions of these clauses of the *add\_overflow\_clause*

### *alter\_overflow\_clause*

The *alter\_overflow\_clause* lets you change the definition of the overflow segment of an existing index-organized table.

The restrictions that apply to the *add\_overflow\_clause* also apply to the *alter\_overflow\_clause*.

#### Note:

When you add a column to an index-organized table, Oracle Database evaluates the maximum size of each column to estimate the largest possible row. If an overflow segment is needed but you have not specified OVERFLOW, then the database raises an error and does not execute the ALTER TABLE statement. This checking function guarantees that subsequent DML operations on the index-organized table will not fail because an overflow segment is lacking.

### *alter\_mapping\_table\_clauses*

The *alter\_mapping\_table\_clauses* is valid only if *table* is index organized and has a mapping table.

#### *allocate\_extent\_clause*

Use the *allocate\_extent\_clause* to allocate a new extent at the end of the mapping table for the index-organized table. Refer to [allocate\\_extent\\_clause](#) for a full description of this clause.

***deallocate\_unused\_clause***

Specify the *deallocate\_unused\_clause* to deallocate unused space at the end of the mapping table of the index-organized table. Refer to [deallocate\\_unused\\_clause](#) for a full description of this clause.

Oracle Database automatically maintains all other attributes of the mapping table or its partitions.

**COALESCE Clause**

Specify COALESCE to instruct Oracle Database to merge the contents of index blocks of the index the database uses to maintain the index-organized table where possible to free blocks for reuse. Refer to the [shrink\\_clause](#) for information on the relationship between these two clauses.

***alter\_XMLSchema\_clause***

This clause is valid as part of *alter\_table\_properties* only if you are modifying an XMLType table with BINARY XML storage. Refer to [XMLSchema\\_spec](#) in the documentation on CREATE TABLE for more information on the ALLOW and DISALLOW clauses.

***column\_clauses***

Use these clauses to add, drop, or otherwise modify a column.

***add\_column\_clause***

The *add\_column\_clause* lets you add a column to a table.

 **See Also:**

[CREATE TABLE](#) for a description of the keywords and parameters of this clause and "Adding a Table Column: Example"

Use ALTER TABLE ADD to associate columns to a domain:

```
ALTER TABLE [owner.]name ADD (<column_list_def_clause> [, DOMAIN  
[domain_owner.]domain_name (<column_name_list>)]+)
```

***column\_definition***

Unless otherwise noted in this section, the elements of *column\_definition* have the same behavior when adding a column to an existing table as they do when creating a new table. Refer to the [column\\_definition](#) clause of CREATE TABLE for information.

**Restriction on *column\_definition***

The SORT parameter is valid only when creating a new table. You cannot specify SORT in the *column\_definition* of an ALTER TABLE ... ADD statement.

When you add a column, the initial value of each row for the new column is null, unless you specify the DEFAULT clause.

You can add an overflow data segment to each partition of a partitioned index-organized table.

You can add LOB columns to nonpartitioned and partitioned tables. You can specify LOB storage at the table and at the partition or subpartition level.

If you previously created a view with a query that used the `SELECT *` syntax to select all columns from table, and you now add a column to `table`, then the database does not automatically add the new column to the view. To add the new column to the view, re-create the view using the `CREATE VIEW` statement with the `OR REPLACE` clause. Refer to [CREATE VIEW](#) for more information.

### Restrictions on Adding Columns

The addition of columns is subject to the following restrictions:

- You cannot add a LOB column or an `INVISIBLE` column to a cluster table.
- If you add a LOB column to a hash-partitioned table, then the only attribute you can specify for the new partition is `TABLESPACE`.
- You cannot add a column with a `NOT NULL` constraint if `table` has any rows unless you also specify the `DEFAULT` clause.
- If you specify this clause for an index-organized table, then you cannot specify any other clauses in the same statement.
- You cannot add a column to a duplicated table.

### DEFAULT

Use the `DEFAULT` clause to specify a default for a new column or a new default for an existing column. Oracle Database assigns this value to the column if a subsequent `INSERT` statement omits a value for the column.

The data type of the expression must match the data type specified for the column. The column must also be large enough to hold this expression.

The `DEFAULT` expression can include any SQL function as long as the function does not return a literal argument, a column reference, or a nested function invocation.

The `DEFAULT` expression can include the sequence pseudocolumns `CURRVAL` and `NEXTVAL`, as long as the sequence exists and you have the privileges necessary to access it. Users who perform subsequent inserts that use the `DEFAULT` expression must have the `INSERT` privilege on the table and the `SELECT` privilege on the sequence. If the sequence is later dropped, then subsequent insert statements where the `DEFAULT` expression is used will result in an error. If you are adding a new column to a table, then the order in which `NEXTVAL` is assigned to each existing row is nondeterministic. If you do not fully qualify the sequence by specifying the sequence owner, for example, `SCOTT.SEQ1`, then Oracle Database will default the sequence owner to be the user who issues the `ALTER TABLE` statement. For example, if user `MARY` adds a column to `SCOTT.TABLE` and refers to a sequence that is not fully qualified, such as `SEQ2`, then the column will use sequence `MARY.SEQ2`. Synonyms on sequences undergo a full name resolution and are stored as the fully qualified sequence in the data dictionary; this is true for public and private synonyms. For example, if user `BETH` adds a column referring to public or private synonym `SYN1` and the synonym refers to `PETER.SEQ7`, then the column will store `PETER.SEQ7` as the default.

If you specify the `DEFAULT` clause for a column, then the default value is stored as metadata but the column itself is not populated with data. However, subsequent queries that specify the

new column are rewritten so that the default value is returned in the result set. This optimized behavior is subject to the following restrictions:

- The table cannot have any LOB columns. It cannot be index-organized, temporary, or part of a cluster. It also cannot be a queue table, an object table, or the container table of a materialized view.
- If the table has a Virtual Private Database (VPD) policy on it, then the optimized behavior will not take place unless the user who issues the `ALTER TABLE ... ADD` statement has the `EXEMPT ACCESS POLICY` system privilege.
- The column being added cannot be encrypted, and cannot be an object column, nested table column, or a LOB column.
- The `DEFAULT` expression cannot include the sequence pseudocolumns `CURRVAL` or `NEXTVAL`.

If the optimized behavior cannot take place due to the preceding restrictions, then Oracle Database updates each row in the newly created column with the default value. In this case, the database does not fire any `UPDATE` triggers that are defined on the table.

### Restrictions on Default Column Values

Default column values are subject to the following restrictions:

- A `DEFAULT` expression cannot contain references to PL/SQL functions or to other columns, the pseudocolumns `LEVEL`, `PRIOR`, and `ROWNUM`, or date constants that are not fully specified.
- The expression can be of any form except a scalar subquery expression.

### ON NULL

If you specify the `ON NULL` clause, then Oracle Database assigns the `DEFAULT` column value when a subsequent `INSERT` or optionally an `UPDATE` statement attempts to assign a value that evaluates to `NULL`.

When you specify `ON NULL`, the `NOT NULL` constraint and `NOT DEFERRABLE` constraint state are implicitly specified. If you specify an inline constraint that conflicts with `NOT NULL` and `NOT DEFERRABLE`, then an error is raised.

Refer to [CREATE TABLE ON NULL](#) for the full semantics of `DEFAULT ON NULL`.

#### See Also:

["Specifying a Default Column Value: Examples"](#)

### *identity\_clause*

The `identity_clause` has the same semantics when you add an identity column that it has when you create an identity column. Refer to [CREATE TABLE identity\\_clause](#) for more information.

When you add a new identity column to a table, all existing rows are updated using the sequence generator. The order in which a value is assigned to each existing row is nondeterministic.

### *identity\_options*

Use the *identity\_options* clause to configure the sequence generator. The *identity\_options* clause has the same parameters as the CREATE SEQUENCE statement. Refer to [CREATE SEQUENCE](#) for a full description of these parameters and characteristics. The exception is START WITH LIMIT VALUE, which is specific to *identity\_options* and can only be used with ALTER TABLE MODIFY. Refer to [identity\\_options](#) for more information.

### *inline\_constraint*

Use *inline\_constraint* to add a constraint to the new column.

### *inline\_ref\_constraint*

This clause lets you describe a new column of type REF. Refer to [constraint](#) for syntax and description of this type of constraint, including restrictions.

### *virtual\_column\_definition*

The *virtual\_column\_definition* has the same semantics when you add a column that it has when you create a column.

#### See Also:

The CREATE TABLE *virtual\_column\_definition* and "Adding a Virtual Table Column: Example" for more information

### Restriction on Adding a Virtual Column

You cannot add a virtual column when the SQL expression for the virtual column involves a column on which an Oracle Data Redaction policy is defined.

### *column\_properties*

The clauses of *column\_properties* determine the storage characteristics of an object type, nested table, varray, or LOB column.

### *object\_type\_col\_properties*

This clause is valid only when you are adding a new object type column or attribute. To modify the properties of an existing object type column, use the *modify\_column\_clauses*. The semantics of this clause are the same as for CREATE TABLE unless otherwise noted.

Use the *object\_type\_col\_properties* clause to specify storage characteristics for a new object column or attribute or an element of a collection column or attribute.

For complete information on this clause, refer to [object\\_type\\_col\\_properties](#) in the documentation on CREATE TABLE.

### *nested\_table\_col\_properties*

The *nested\_table\_col\_properties* clause lets you specify separate storage characteristics for a nested table, which in turn lets you define the nested table as an index-organized table. You must include this clause when creating a table with columns or column attributes

whose type is a nested table. (Clauses within this clause that function the same way they function for parent object tables are not repeated here. See the CREATE TABLE clause *nested\_table\_col\_properties* for more information about these clauses.)

- For *nested\_item*, specify the name of a column (or a top-level attribute of the nested table object type) whose type is a nested table.  
If the nested table is a multilevel collection, and the inner nested table does not have a name, then specify COLUMN\_VALUE in place of the *nested\_item* name.
- For *storage\_table*, specify the name of the table where the rows of *nested\_item* reside. The storage table is created in the same schema and the same tablespace as the parent table.

### Restrictions on Nested Table Column Properties

Nested table column properties are subject to the following restrictions:

- You cannot specify the *parallel\_clause*.
- You cannot specify CLUSTER as part of the *physical\_properties* clause.

#### See Also:

"[Nested Tables: Examples](#)"

### *varray\_col\_properties*

The *varray\_col\_properties* clause lets you specify separate storage characteristics for the LOB in which a varray will be stored. If you specify this clause, then Oracle Database will always store the varray in a LOB, even if it is small enough to be stored inline. If *varray\_item* is a multilevel collection, then the database stores all collection items nested within *varray\_item* in the same LOB in which *varray\_item* is stored.

### Restriction on Varray Column Properties

You cannot specify TABLESPACE as part of *LOB\_parameters* for a varray column. The LOB tablespace for a varray defaults to the tablespace of the containing table.

### *out\_of\_line\_part\_storage*

This clause lets you specify storage attributes the newly added column for each partition or subpartition in a partitioned table. For any partition or subpartition you do not name in this clause, the storage attributes for the new column are the same as those specified in the *nested\_table\_col\_properties* at the table level.

### *LOB\_storage\_clause*

Use the *LOB\_storage\_clause* to specify the LOB storage characteristics for a newly added LOB column, LOB partition, or LOB subpartition, or when you are converting a LONG column into a LOB column. You cannot use this clause to modify an existing LOB. Instead, you must use the [modify\\_LOB\\_storage\\_clause](#).

Unless otherwise noted in this section, all LOB parameters, in both the *LOB\_storage\_clause* and the [modify\\_LOB\\_storage\\_clause](#), have the same semantics

in an ALTER TABLE statement that they have in a CREATE TABLE statement. Refer to the CREATE TABLE [LOB\\_storage\\_clause](#) for complete information on this clause.

### Restriction on LOB Parameters

The only parameter of *LOB\_parameters* you can specify for a hash partition or hash subpartition is TABLESPACE.

### CACHE READS Clause

When you add a new LOB column, you can specify the logging attribute with CACHE READS, as you can when defining a LOB column at create time. Refer to the CREATE TABLE clause [CACHE READS](#) for full information on this clause.

### ENABLE | DISABLE STORAGE IN ROW

You cannot change STORAGE IN ROW once it is set. Therefore, you cannot specify this clause as part of the *modify\_col\_properties* clause. However, you can change this setting when adding a new column ([add\\_column\\_clause](#)) or when moving the table ([move\\_table\\_clause](#)). Refer to the CREATE TABLE clause [ENABLE STORAGE IN ROW](#) for complete information on this clause.

### CHUNK *integer*

You use cannot use the *modify\_col\_properties* clause to change the value of CHUNK after it has been set. If you require a different CHUNK value for a column after it has been created, use ALTER TABLE ... MOVE. Refer to the CREATE TABLE clause [CHUNK integer](#) for more information.

### RETENTION

For BasicFiles LOBs, if the database is in automatic undo mode, then you can specify RETENTION instead of PCTVERSION to instruct Oracle Database to retain old versions of this LOB. This clause overrides any prior setting of PCTVERSION. Refer to the CREATE TABLE clause [LOB\\_retention\\_clause](#) for a full description of this parameter.

### FREEPOOLS *integer*

For BasicFiles LOBs, if the database is in automatic undo mode, then you can use this clause to specify the number of freelist groups for this LOB. This clause overrides any prior setting of FREELIST GROUPS. Refer to the CREATE TABLE clause [FREEPOOLS integer](#) for a full description of this parameter. The database ignores this parameter for SecureFiles LOBs.

### *LOB\_partition\_storage*

You can specify only one list of *LOB\_partition\_storage* clauses in a single ALTER TABLE statement, and all *LOB\_storage\_clauses* and *varray\_col\_properties* clause must precede the list of *LOB\_partition\_storage* clauses. Refer to the CREATE TABLE clause [LOB\\_partition\\_storage](#) for full information on this clause, including restrictions.

### *XMLType\_column\_properties*

Refer to the CREATE TABLE clause [XMLType\\_column\\_properties](#) for a full description of this clause.

 See Also:

- [LOB\\_storage\\_clause](#) for information on the `LOB_segnname` and `LOB_parameters` clauses
- "XMLType Column Examples" for an example of `XMLType` columns in object-relational tables and "Using XML in SQL Statements" for an example of creating an XMLSchema
- *Oracle XML DB Developer's Guide* for more information on `XMLType` columns and tables and on creating an XMLSchema

***XMLType\_storage***

Refer to the `CREATE TABLE` clause [XMLType\\_storage](#).

***JSON\_storage\_clause***

With 21c you can define a column of `JSON` data type using the `JSON_storage_clause`.

**Example**

```
ALTER TABLE t ADD (jcol JSON)
```

***modify\_column\_clauses***

Use the `modify_column_clauses` to modify the properties of an existing column, the visibility of an existing column, or the substitutability of an existing object type column.

 See Also:

- "[Modifying Table Columns: Examples](#)"

***modify\_col\_properties***

Use this clause to modify the properties of the column. Any of the optional parts of the column definition (data type, default value, or constraint) that you omit from this clause remain unchanged.

***datatype***

You can change the data type of any column if all rows of the column contain nulls. However, if you change the data type of a column in a materialized view container table, then Oracle Database invalidates the corresponding materialized view.

You can omit the data type only if the statement also designates the column as part of the foreign key of a referential integrity constraint. The database automatically assigns the column the same data type as the corresponding column of the referenced key of the referential integrity constraint.

You can always increase the size of a character or raw column or the precision of a numeric column, whether or not all the rows contain nulls. You can reduce the size of a data type of a column as long as the change does not require data to be modified. The

database scans existing data and returns an error if data exists that exceeds the new length limit.

When you increase the size of a `VARCHAR2`, `NVARCHAR2`, or `RAW` column to exceed 4000 bytes, Oracle Database performs an in-place length extension and does not migrate the inline storage to external LOB storage. This enables uninterrupted migration of large tables, especially after migration, to leverage extended data types. However, the inline storage of the column will not be preserved during table reorganization operations, such as `CREATE TABLE ... AS SELECT`, export, import, or online redefinition. To migrate to the new out-of-line storage of extended data type columns, you must recreate the table using one of the aforementioned methods. The inline storage of the column will be preserved during table or partition movement operations, such as `ALTER TABLE MOVE [ [SUB] PARTITION]`, and partition maintenance operations, such as `ALTER TABLE SPLIT [SUB] PARTITION`, `ALTER TABLE MERGE [SUB] PARTITIONS`, and `ALTER TABLE COALESCE [SUB] PARTITIONS`.

 **Note:**

Oracle recommends against excessively increasing the size of a `VARCHAR2`, `NVARCHAR2`, or `RAW` column beyond 4000 bytes for the following reasons:

- Row chaining may occur.
- Data that is stored inline must be read in its entirety, whether a column is selected or not. Therefore, extended data type columns that are stored inline can have a negative impact on performance.

You can reduce the size of a data type of a column as long as the change does not require data to be modified. The database scans existing data and returns an error if data exists that exceeds the new length limit.

You can change a `DATE` column to a `TIMESTAMP` or `TIMESTAMP WITH LOCAL TIME ZONE` column, and you can change a `TIMESTAMP` or `TIMESTAMP WITH LOCAL TIME ZONE` column to a `DATE` column. The following rules apply:

- When you change a `TIMESTAMP` or `TIMESTAMP WITH LOCAL TIME ZONE` column to a `DATE` column, Oracle Database updates each column value that has nonzero fractional seconds by rounding the value to the nearest second. If, while updating such a value, Oracle Database encounters a minute field greater than or equal to 60 (which can occur in a boundary case when the daylight saving rule switches), then it updates the minute field by subtracting 60 from it.
- After you change a `TIMESTAMP WITH LOCAL TIME ZONE` column to a `DATE` column, the values in the column still represent the local time that they represented in the database time zone. However, the database time zone is no longer associated with the values. When queried in SQL\*Plus, the values are no longer automatically adjusted to the session time zone. It is now the responsibility of applications processing the column values to interpret them in a particular time zone.

If the table is empty, then you can increase or decrease the leading field or the fractional second value of a datetime or interval column. If the table is not empty, then you can only increase the leading field or fractional second of a datetime or interval column.

You can use the `TO_LOB` function to change a `LONG` column to a `CLOB` or `NCLOB` column, and a `LONG RAW` column to a `BLOB` column. However, you cannot use the `TO_LOB` function from within a PL/SQL package. Instead use the `TO_CLOB (character)` or `TO_BLOB (raw)` functions.

- The modified LOB column inherits all constraints and triggers that were defined on the original `LONG` column. If you want to change any constraints, then you must do so in a subsequent `ALTER TABLE` statement.
- If any domain indexes are defined on the `LONG` column, then you must drop them before modifying the column to a LOB.
- After the modification, you will have to rebuild all other indexes on all columns of the table.

You can use the `TO_CLOB` (character) function to convert `NCLOB` columns `CLOB` columns.

#### See Also:

- *Oracle Database SecureFiles and Large Objects Developer's Guide* for information on `LONG` to LOB migration
- [ALTER INDEX](#) for information on dropping and rebuilding indexes

For `CHAR` and `VARCHAR2` columns, you can change the length semantics by specifying `CHAR` (to indicate character semantics for a column that was originally specified in bytes) or `BYTE` (to indicate byte semantics for a column that was originally specified in characters). To learn the length semantics of existing columns, query the `CHAR_USED` column of the `ALL_`, `USER_`, or `DBA_TAB_COLUMNS` data dictionary view.

#### See Also:

- *Oracle Database Globalization Support Guide* for information on byte and character semantics
- *Oracle Database Reference* for information on the data dictionary views

You can specify a user-defined datatype as non-persistable when creating or altering the datatype. Instances of non-persistable types cannot persist on disk. See [CREATE TYPE](#) for more on user-defined datatypes declared as non-persistable types.

### DOMAIN

Use this clause to associate `domain_name` with the column. The domain's data type must be compatible with the column's data type.

### COLLATE

Use this clause to set or change the data-bound collation for a column. For `column_collation_name`, specify a valid named collation or pseudo-collation. Refer to the [DEFAULT COLLATION](#) clause of `CREATE TABLE` for more information on data-bound collations.

#### Restrictions on Changing Column Collation

The modification of the column collation is subject to the following restrictions:

- If the column belongs to an index key, then its collation can only be changed:

- among collations: BINARY, USING\_NLS\_COMP, USING\_NLS\_SORT, and USING\_NLS\_SORT\_CS
  - between collations BINARY\_CI and USING\_NLS\_SORT\_CI
  - between collations BINARY\_AI and USING\_NLS\_SORT\_AI
- If the column belongs to a range- or list-partitioning key, is referenced by a bitmap join index, belongs to the primary key of an index-organized table, or to the key of a domain index, including an Oracle Text index, then its collation can only be changed among the collations BINARY, USING\_NLS\_COMP, USING\_NLS\_SORT, and USING\_NLS\_SORT\_CS.
  - If the column belongs to an attribute clustering key, then its collation can only be changed between the collations BINARY and USING\_NLS\_COMP.

#### See Also:

[Modifying the Collation of a Column for Fine-Grained Case-Insensitivity: Example](#)

#### *identity\_clause*

Use *identity\_clause* to modify the properties of an identity column. You cannot specify this clause on a column that is not an identity column. If you do not specify ALWAYS or BY DEFAULT, then the current generation type is retained. Refer to CREATE TABLE *identity\_clause* for more information on ALWAYS and BY DEFAULT.

#### *identity\_options*

Use the *identity\_options* clause to configure the sequence generator. The *identity\_options* clause has the same parameters as the CREATE SEQUENCE statement. Refer to CREATE SEQUENCE for a full description of these parameters and characteristics. The exceptions are:

- START WITH LIMIT VALUE, which is specific to *identity\_options*, can only be used with ALTER TABLE MODIFY. If you specify START WITH LIMIT VALUE, then Oracle Database locks the table and finds the maximum identity column value in the table (for increasing sequences) or the minimum identity column value (for decreasing sequences) and assigns the value as the sequence generator's high water mark. The next value returned by the sequence generator will be the high water mark + INCREMENT BY *integer* for increasing sequences, or the high water mark - INCREMENT BY *integer* for decreasing sequences.
- If you change the value of START WITH, then the default values will be used for all other parameters in this clause unless you specify otherwise.

#### DROP IDENTITY

Use this clause to remove the identity property from a column, including the sequence generator and NOT NULL and NOT DEFERRABLE constraints. Identity column values in existing rows are not affected.

#### ENCRYPT *encryption\_spec* | DECRYPT

Use this clause to decrypt an encrypted column, to encrypt an unencrypted column, or to change the integrity algorithm or the SALT option of an encrypted column.

When encrypting an existing column, if you specify `encryption_spec`, it must match the encryption specification of any other encrypted columns in the same table. Refer to the `CREATE TABLE` clause `encryption_spec` for additional information and restrictions on the `encryption_spec`.

If a materialized view log is defined on the table, then Oracle Database encrypts or decrypts in the materialized view log any columns you encrypt or decrypt in this clause.

### Restrictions on ENCRYPT `encryption_spec` | DECRYPT

This clause is subject to the following restrictions:

- If the new or existing column is a LOB column, then it must be stored as a SecureFiles LOB, and you cannot specify the `SALT` option.
- You cannot encrypt or decrypt a column on which a fine-grained audit policy for the `UPDATE` statement is enabled. However, you can disable the fine-grained audit policy, encrypt or decrypt the column, and then enable the fine-grained audit policy.

#### See Also:

["Data Encryption: Examples"](#)

### *inline\_constraint*

This clause lets you add a constraint to a column you are modifying. To change the state of existing constraints on existing columns, use the `constraint_clauses`.

### *LOB\_storage\_clause*

The `LOB_storage_clause` is permitted within `modify_col_properties` only if you are converting a `LONG` column to a LOB column. In this case only, you can specify LOB storage for the column using the `LOB_storage_clause`. However, you can specify only the single column as a `LOB_item`. Default LOB storage attributes are used for any attributes you omit in the `LOB_storage_clause`.

### *alter\_XMLSchema\_clause*

This clause is valid within `modify_col_properties` only for `XMLType` tables with `BINARY XML` storage. Refer to `XMLSchema_spec` in the documentation on `CREATE TABLE` for more information on the `ALLOW` and `DISALLOW` clauses.

### Restrictions on Modifying Column Properties

The modification of column properties is subject to the following restrictions:

- You cannot change the data type of a LOB column.
- You cannot modify a column of a table if a domain index is defined on the column. You must first drop the domain index and then modify the column.
- You cannot modify the data type or length of a column that is part of the partitioning or subpartitioning key of a table or index.

- You can change a CHAR column to VARCHAR2 (or VARCHAR) and a VARCHAR2 (or VARCHAR) column to CHAR only if the BLANK\_TRIMMING initialization parameter is set to TRUE and the column size stays the same or increases. If the BLANK\_TRIMMING initialization parameter is set to TRUE, then you can also reduce the column size to any size greater than or equal to the maximum trimmed data value.
- You cannot change a LONG or LONG RAW column to a LOB if the table is part of a cluster. If you do change a LONG or LONG RAW column to a LOB, then the only other clauses you can specify in this ALTER TABLE statement are the DEFAULT clause and the *LOB\_storage\_clause*.
- You can specify the *LOB\_storage\_clause* as part of *modify\_col\_properties* only when you are changing a LONG or LONG RAW column to a LOB.
- You cannot specify a column of data type ROWID for an index-organized table, but you can specify a column of type UROWID.
- You cannot change the data type of a column to REF.
- You cannot modify the properties of a column in a duplicated table.

#### See Also:

[ALTER MATERIALIZED VIEW](#) for information on revalidating a materialized view

### ***modify\_virtcol\_properties***

This clause lets you modify a virtual column in the following ways:

- Specify the COLLATE clause to set or change the data-bound collation for a virtual column. For *column\_collation\_name*, specify a valid named collation or pseudo-collation. Refer to the [DEFAULT COLLATION](#) clause of CREATE TABLE for more information on data-bound collations.
- If the virtual column refers to an editioned PL/SQL function, then you can modify the evaluation edition or the unusable editions for a virtual column. The *evaluation\_edition\_clause* and the *unusable\_editions\_clause* have the same semantics when you modify a virtual column that they have when you create a virtual column. For complete information, refer to [evaluation\\_edition\\_clause](#) and [unusable\\_editions\\_clause](#) in the documentation on CREATE TABLE.

### **Restrictions on Modifying Virtual Columns**

The following restrictions apply to modifying virtual columns:

- Specifying the COLLATE clause to set or change the data-bound collation for a virtual column is subject to the restrictions listed in [Restrictions on Changing Column Collation](#).
- If an index is defined on a virtual column and you modify its evaluation edition or unusable editions, then the database will invalidate all indexes on the virtual column. If you attempt to modify any other properties of the virtual column, then an error occurs.

### ***modify\_col\_visibility***

Use this clause to change the visibility of *column*. For complete information, refer to "[VISIBLE | INVISIBLE](#)" in the documentation on CREATE TABLE.

## Restriction on Modifying Column Visibility

You cannot change a VISIBLE column to INVISIBLE in a table owned by SYS.

### *modify\_col\_substitutable*

Use this clause to set or change the substitutability of an existing object type column.

The FORCE keyword drops any hidden columns containing typeid information or data for subtype attributes. You must specify FORCE if the column or any attributes of its type are not FINAL.

## Restrictions on Modifying Column Substitutability

The modification of column substitutability is subject to the following restrictions:

- You can specify this clause only once in any ALTER TABLE statement.
- You cannot modify the substitutability of a column in an object table if the substitutability of the table itself has been set.
- You cannot specify this clause if the column was created or added using the IS OF TYPE syntax, which limits the range of subtypes permitted in an object column or attribute to a particular subtype. Refer to [substitutable\\_column\\_clause](#) in the documentation on CREATE TABLE for information on the IS OF TYPE syntax.
- You cannot change a varray column to NOT SUBSTITUTABLE, even by specifying FORCE, if any of its attributes are nested object types that are not FINAL.

### *modify\_domain::=*

Use this clause to add or remove a domain from the table.

#### ADD DOMAIN

Use this to add a domain to the listed columns. You must specify as many columns as the domain. The first column is associated with the first domain column, second column is associated with the second domain column, and so on.

#### Example: Create a Domain phone\_number and Add a Column

```
CREATE DOMAIN phone_number AS VARCHAR2(12)
  CONSTRAINT CHECK (phone_number NOT LIKE '%[0-9]%' )
  NOT NULL;
```

To add a new column to a table with domain, the ALTER TABLE statement can be used as follows:

```
ALTER TABLE customers ADD (cust_cell_phone_number Varchar2(12) DOMAIN
  phone_number);
```

```
ALTER TABLE customers ADD (cust_cell_phone_number Varchar2(12) DOMAIN
  phone_number DEFAULT ON NULL '650-000-0000');
```

#### DROP DOMAIN

Use this clause to dissociate a domain from the listed columns. The number of columns in this statement must match the number of columns in the domain.

If the domain has a collation, this will be preserved.

## PRESERVE CONSTRAINTS

By default, any constraints from the domain are removed from the column. Use this clause to copy the domain constraints to the column.

### ***drop\_column\_clause***

The *drop\_column\_clause* lets you free space in the database by dropping columns you no longer need or by marking them to be dropped at a future time when the demand on system resources is less.

- If you drop a nested table column, then its storage table is removed.
- If you drop a LOB column, then the LOB data and its corresponding LOB index segment are removed.
- If you drop a BFILE column, then only the locators stored in that column are removed, not the files referenced by the locators.
- If you drop or mark unused a column defined as an `INCLUDING` column, then the column stored immediately before this column will become the new `INCLUDING` column.

## SET UNUSED Clause

Specify `SET UNUSED` to mark one or more columns as unused. For an internal heap-organized table, specifying this clause does not actually remove the target columns from each row in the table. It does not restore the disk space used by these columns. Therefore, the response time is faster than when you execute the `DROP` clause.

When you specify this clause for a column in an external table, the clause is transparently converted to an `ALTER TABLE ... DROP COLUMN` statement. The reason for this is that any operation on an external table is a metadata-only operation, so there is no difference in the performance of the two commands.

You can view all tables with columns marked `UNUSED` in the data dictionary views `USER_UNUSED_COL_TABS`, `DBA_UNUSED_COL_TABS`, and `ALL_UNUSED_COL_TABS`.

### See Also:

*Oracle Database Reference* for information on the data dictionary views

Unused columns are treated as if they were dropped, even though their column data remains in the table rows. After a column has been marked `UNUSED`, you have no access to that column. A `SELECT *` query will not retrieve data from unused columns. In addition, the names and types of columns marked `UNUSED` will not be displayed during a `DESCRIBE`, and you can add to the table a new column with the same name as an unused column.

 **Note:**

Until you actually drop these columns, they continue to count toward the maximum number of columns in a single table, i.e. 1000 if the `MAX_COLUMNS` initialization parameter is set to `STANDARD`, or 4096 columns if `MAX_COLUMNS` is set to `EXTENDED`. However, as with all DDL statements, you cannot roll back the results of this clause. You cannot issue `SET USED` counterpart to retrieve a column that you have `SET UNUSED`. Refer to [CREATE TABLE](#) for more information on the 1000-column limit.

Also, if you mark a `LONG` column as `UNUSED`, then you cannot add another `LONG` column to the table until you actually drop the unused `LONG` column.

## ONLINE

Specify `ONLINE` to indicate that DML operations on the table will be allowed while marking the column or columns `UNUSED`.

### Restrictions on Marking Columns Unused

The following restrictions apply to the `SET UNUSED` clause:

- You cannot specify the `ONLINE` clause when marking a column with a `DEFERRABLE` constraint as `UNUSED`.
- Columns in tables owned by `SYS` cannot be marked as `UNUSED`.

### DROP Clause

Specify `DROP` to remove the column descriptor and the data associated with the target column from each row in the table. If you explicitly drop a particular column, then all columns currently marked `UNUSED` in the target table are dropped at the same time.

When the column data is dropped:

- All indexes defined on any of the target columns are also dropped.
- All constraints that reference a target column are removed.
- If any statistics types are associated with the target columns, then Oracle Database disassociates the statistics from the column with the `FORCE` option and drops any statistics collected using the statistics type.

 **Note:**

If the target column is a parent key of a nontarget column, or if a check constraint references both the target and nontarget columns, then Oracle Database returns an error and does not drop the column unless you have specified the `CASCADE CONSTRAINTS` clause. If you have specified that clause, then the database removes all constraints that reference any of the target columns.

 See Also:

[DISASSOCIATE STATISTICS](#) for more information on disassociating statistics types

### DROP UNUSED COLUMNS Clause

Specify `DROP UNUSED COLUMNS` to remove from the table all columns currently marked as unused. Use this statement when you want to reclaim the extra disk space from unused columns in the table. If the table contains no unused columns, then the statement returns with no errors.

#### *column*

Specify one or more columns to be set as unused or dropped. Use the `COLUMN` keyword only if you are specifying only one column. If you specify a column list, then it cannot contain duplicates.

### CASCADE CONSTRAINTS

Specify `CASCADE CONSTRAINTS` if you want to drop all foreign key constraints that refer to the primary and unique keys defined on the dropped columns as well as all multicolumn constraints defined on the dropped columns. If any constraint is referenced by columns from other tables or remaining columns in the target table, then you must specify `CASCADE CONSTRAINTS`. Otherwise, the statement aborts and an error is returned.

### INVALIDATE

The `INVALIDATE` keyword is optional. Oracle Database automatically invalidates all dependent objects, such as views, triggers, and stored program units. Object invalidation is a recursive process. Therefore, all directly dependent and indirectly dependent objects are invalidated. However, only local dependencies are invalidated, because the database manages remote dependencies differently from local dependencies.

An object invalidated by this statement is automatically revalidated when next referenced. You must then correct any errors that exist in that object before referencing it.

 See Also:

[Oracle Database Concepts](#) for more information on dependencies

### CHECKPOINT

Specify `CHECKPOINT` if you want Oracle Database to apply a checkpoint for the `DROP COLUMN` operation after processing *integer* rows; *integer* is optional and must be greater than zero. If *integer* is greater than the number of rows in the table, then the database applies a checkpoint after all the rows have been processed. If you do not specify *integer*, then the database sets the default of 512. Checkpointing cuts down the amount of undo logs accumulated during the `DROP COLUMN` operation to avoid running out of undo space. However, if this statement is interrupted after a checkpoint has been applied, then the table remains in an unusable state. While the table is unusable, the only operations allowed on it are `DROP`

TABLE, TRUNCATE TABLE, and ALTER TABLE DROP ... COLUMNS CONTINUE (described in sections that follow).

You cannot use this clause with SET UNUSED, because that clause does not remove column data.

### DROP COLUMNS CONTINUE Clause

Specify DROP COLUMNS CONTINUE to continue the drop column operation from the point at which it was interrupted. Submitting this statement while the table is in an invalid state results in an error.

### Restrictions on Dropping Columns

Dropping columns is subject to the following restrictions:

- Each of the parts of this clause can be specified only once in the statement and cannot be mixed with any other ALTER TABLE clauses. For example, the following statements are not allowed:

```
ALTER TABLE t1 DROP COLUMN f1 DROP (f2);
ALTER TABLE t1 DROP COLUMN f1 SET UNUSED (f2);
ALTER TABLE t1 DROP (f1) ADD (f2 NUMBER);
ALTER TABLE t1 SET UNUSED (f3)
    ADD (CONSTRAINT ck1 CHECK (f2 > 0));
```

- You can drop an object type column only as an entity. To drop an attribute from an object type column, use the ALTER TYPE ... DROP ATTRIBUTE statement with the CASCADE INCLUDING TABLE DATA clause. Be aware that dropping an attribute affects all dependent objects. See *Oracle Database PL/SQL Language Reference* for more information.
- You can drop a column from an index-organized table only if it is not a primary key column. The primary key constraint of an index-organized table can never be dropped, so you cannot drop a primary key column even if you have specified CASCADE CONSTRAINTS.
- You can export tables with dropped or unused columns. However, you can import a table only if all the columns specified in the export files are present in the table (none of those columns has been dropped or marked unused). Otherwise, Oracle Database returns an error.
- You can set unused a column from a table that uses COMPRESS BASIC, but you cannot drop the column. However, all clauses of the *drop\_column\_clause* are valid for tables that use ROW STORE COMPRESS ADVANCED. See the semantics for *table\_compression* for more information.
- You cannot drop a column on which a domain index has been built.
- You cannot drop a SCOPE table constraint or a WITH ROWID constraint on a REF column.
- You cannot use this clause to drop:
  - A pseudocolumn, cluster column, or partitioning column. You can drop nonpartitioning columns from a partitioned table if all the tablespaces where the partitions were created are online and in read/write mode.
  - A column from a nested table, an object table, a duplicated table, or a table owned by SYS.

 See Also:

["Dropping a Column: Example"](#)

***add\_period\_clause***

Use the *add\_period\_clause* to add a valid time dimension to *table*.

The *period\_definition* clause of ALTER TABLE has the same semantics as in CREATE TABLE, with the following exceptions and additions:

- *valid\_time\_column* must not already exist in *table*.
- If you specify *start\_time\_column* and *end\_time\_column*, then these columns must already exist in *table* or you must specify the *add\_column\_clause* for each of these columns.
- If you specify *start\_time\_column* and *end\_time\_column* and these columns already exist in *table* and are populated with data, then for all rows where both columns have non-NULL values, the value of *start\_time\_column* must be earlier than the value of *end\_time\_column*.

 See Also:

[CREATE TABLE \*period\\_definition\*](#) for the full semantics of this clause

***drop\_period\_clause***

Use the *drop\_period\_clause* to drop a valid time dimension from *table*.

For *valid\_time\_column*, specify the name of the valid time dimension you want to drop.

This clause has the following effects:

- The *valid\_time\_column* will be dropped from *table*.
- If the start time column and end time column were automatically created by Oracle Database when the valid time dimension was created, either with CREATE TABLE ... *period\_definition* or ALTER TABLE ... *add\_period\_clause*, then they will be dropped. Otherwise, these columns will remain in *table* and revert to regular table columns.

 See Also:

[CREATE TABLE \*period\\_definition\*](#) for more information on the *valid\_time\_column*, start time column, and end time column

***rename\_column\_clause***

Use the *rename\_column\_clause* to rename a column of *table*. The new column name must not be the same as any other column name in *table*.

When you rename a column, Oracle Database handles dependent objects as follows:

- Function-based indexes and check constraints that depend on the renamed column remain valid.
- Dependent views, triggers, functions, procedures, and packages are invalidated. Oracle Database attempts to revalidate them when they are next accessed, but you may need to alter these objects with the new column name if revalidation fails.
- If a domain index is defined on the column being renamed, then the database invokes the ODCIIndexAlter method with the `RENAME` option. This operation establishes correspondence between the indextype metadata and the base table

### Restrictions on Renaming Columns

Renaming columns is subject to the following restrictions:

- You cannot combine this clause with any of the other `column_clauses` in the same statement.
- You cannot rename a column that is used to define a join index. Instead you must drop the index, rename the column, and re-create the index.
- You cannot rename a column in a duplicated table.

#### See Also:

["Renaming a Column: Example"](#)

### *modify\_collection\_retrieval*

Use the `modify_collection_retrieval` clause to change what Oracle Database returns when a collection item is retrieved from the database.

#### *collection\_item*

Specify the name of a column-qualified attribute whose type is nested table or varray.

#### **RETURN AS**

Specify what Oracle Database should return as the result of a query:

- `LOCATOR` specifies that a unique locator for the nested table is returned.
- `VALUE` specifies that a copy of the nested table itself is returned.

#### See Also:

["Collection Retrieval: Example"](#)

### *modify\_LOB\_storage\_clause*

The `modify_LOB_storage_clause` lets you change the physical attributes of `LOB_item`. You can specify only one `LOB_item` for each `modify_LOB_storage_clause`.

The sections that follow describe the semantics of parameters specific to `modify_LOB_parameters`. Unless otherwise documented in this section, the remaining LOB parameters have the same semantics when altering a table that they have when you are creating a table. Refer to the restrictions at the end of this section and to the `CREATE TABLE` clause `LOB_storage_parameters` for more information.

 **Note:**

- You can modify LOB storage with an `ALTER TABLE` statement or with online redefinition by using the `DBMS_REDEFINITION` package. If you have not enabled LOB encryption, compression, or deduplication at create time, Oracle recommends that you use online redefinition to enable them after creation, as this process is more disk space efficient for changes to these three parameters. See *Oracle Database PL/SQL Packages and Types Reference* for more information on `DBMS_REDEFINITION`.
- You cannot convert a LOB from one type of storage to the other. Instead you must migrate to SecureFiles or BasicFiles by using online redefinition or partition exchange.

#### **PCTVERSION integer**

Refer to the `CREATE TABLE` clause `PCTVERSION integer` for information on this clause.

#### ***LOB\_retention\_clause***

If the database is in automatic undo mode, then you can specify `RETENTION` instead of `PCTVERSION` to instruct Oracle Database to retain old versions of this LOB. This clause overrides any prior setting of `PCTVERSION`.

#### ***FREEPOOLS integer***

For BasicFiles LOBs, if the database is in automatic undo mode, then you can use this clause to specify the number of freelist groups for this LOB. This clause overrides any prior setting of `FREELIST GROUPS`. Refer to the `CREATE TABLE` clause `FREEPOOLS integer` for a full description of this parameter. The database ignores this parameter for SecureFiles LOBs.

#### **REBUILD FREEPOOLS**

This clause applies only to BasicFiles LOBs, not to SecureFiles LOBs. The `REBUILD FREEPOOLS` clause removes all the old versions of data from the LOB column. This clause is useful for removing all retained old version space in a LOB segment, freeing that space to be used immediately by new LOB data.

#### ***LOB\_deduplicate\_clause***

This clause is valid only for SecureFiles LOBs. `KEEP_DUPLICATES` disables LOB deduplication. `DEDUPPLICATE` enables LOB deduplication. All lobs in the segment are read, and any matching LOBs are deduplicated before returning.

#### ***LOB\_compression\_clause***

This clause is valid only for SecureFiles LOBs. `COMPRESS` compresses all LOBs in the segment and then returns. `NOCOMPRESS` uncompresses all LOBs in the segment and then returns.

## ENCRYPT | DECRYPT

LOB encryption has the same semantics as column encryption in general. See "[ENCRYPT encryption\\_spec | DECRYPT](#)" for more information.

## CACHE, NOCACHE, CACHE READS

When you modify a LOB column from CACHE or NOCACHE to CACHE READS, or from CACHE READS to CACHE or NOCACHE, you can change the logging attribute. If you do not specify LOGGING or NOLOGGING, then this attribute defaults to the current logging attribute of the LOB column. If you do not specify CACHE, NOCACHE, or CACHE READS, then Oracle Database retains the existing values of the LOB attributes.

### Restrictions on Modifying LOB Storage

Modifying LOB storage is subject to the following restrictions:

- You cannot modify the value of the `INITIAL` parameter in the `storage_clause` when modifying the LOB storage attributes.
- You cannot specify both the `allocate_extent_clause` and the `deallocate_unused_clause` in the same statement.
- You cannot specify both the `PCTVERSION` and `RETENTION` parameters.
- You cannot specify the `shrink_clause` for SecureFiles LOBs.

#### See Also:

[LOB\\_storage\\_clause](#) (in CREATE TABLE) for information on setting LOB parameters and "[LOB Columns: Examples](#)"

## `alter_varray_col_properties`

The `alter_varray_col_properties` clause lets you change the storage characteristics of an existing LOB in which a varray is stored.

### Restriction on Altering Varray Column Properties

You cannot specify the `TABLESPACE` clause of `LOB_parameters` as part of this clause. The LOB tablespace for a varray defaults to the tablespace of the containing table.

## `REKEY encryption_spec`

The `REKEY` clause causes the database to generate a new encryption key. All encrypted columns in the table are reencrypted using the new key and, if you specify the `USING` clause of the `encryption_spec`, a new encryption algorithm. You cannot combine this clause with any other clauses in this `ALTER TABLE` statement.

#### See Also:

[Oracle Database Advanced Security Guide](#) for more information on transparent column encryption

### ***constraint\_clauses***

Use the *constraint\_clauses* to add a new constraint using out-of-line declaration, modify the state of an existing constraint, or drop a constraint. Refer to [constraint](#) for a description of all the keywords and parameters of out-of-line constraints and *constraint\_state*.

#### **Adding a Constraint**

The `ADD` clause lets you add a new out-of-line constraint or out-of-line `REF` constraint to the table.

#### **Restrictions on Adding a Constraint**

Adding constraints is subject to the following restrictions:

- You cannot add a constraint to a duplicated table.
- You cannot add a foreign key constraint to a sharded table.

#### **See Also:**

["Disabling a CHECK Constraint: Example"](#), ["Specifying Object Identifiers: Example"](#), and ["REF Columns: Examples"](#)

#### **Modifying a Constraint**

The `MODIFY CONSTRAINT` clause lets you change the state of an existing constraint.

The `CASCADE` keyword is valid only when you are disabling a unique or primary key constraint on which a foreign key constraint is defined. In this case, you must specify `CASCADE` so that the unique or primary key constraint and all of its dependent foreign key constraints are disabled.

Like the other constraint states you can set the precheck state of a constraint to `PRECHECK` and unset it with `NOPRECHECK`.

#### **Restrictions on Modifying Constraints**

Modifying constraints is subject to the following restrictions:

- You cannot change the state of a `NOT DEFERRABLE` constraint to `INITIALLY DEFERRED`.
- If you specify this clause for an index-organized table, then you cannot specify any other clauses in the same statement.
- You cannot change the `NOT NULL` constraint on a foreign key column of a reference-partitioned table, and you cannot change the state of a partitioning referential constraint of a reference-partitioned table.
- You cannot modify a constraint on a duplicated table.
- You can specify `precheck_state` only with `constraint_name`. Primary key and unique constraints are not supported.

 See Also:

- ["Adding and Modifying Precheck State Constraint: Example"](#)
- ["Changing the State of a Constraint: Examples"](#)
- ["Explicitly Declaring Column Check Constraints Precheckable or Not"](#)

**Renaming a Constraint**

The `RENAME CONSTRAINT` clause lets you rename any existing constraint on `table`. The new constraint name cannot be the same as any existing constraint on any object in the same schema. All objects that are dependent on the constraint remain valid.

 See Also:

- ["Renaming Constraints: Example"](#)

**`drop_constraint_clause`**

The `drop_constraint_clause` lets you drop an integrity constraint from the database. Oracle Database stops enforcing the constraint and removes it from the data dictionary. You can specify only one constraint for each `drop_constraint_clause`, but you can specify multiple `drop_constraint_clause` in one statement.

**PRIMARY KEY**

Specify `PRIMARY KEY` to drop the primary key constraint of `table`.

**UNIQUE**

Specify `UNIQUE` to drop the unique constraint on the specified columns.

If you drop the primary key or unique constraint from a column on which a bitmap join index is defined, then Oracle Database invalidates the index. See [CREATE INDEX](#) for information on bitmap join indexes.

**CONSTRAINT**

Specify `CONSTRAINT constraint_name` to drop an integrity constraint other than a primary key or unique constraint.

**CASCADE**

Specify `CASCADE` if you want all other integrity constraints that depend on the dropped integrity constraint to be dropped as well.

**KEEP INDEX | DROP INDEX**

Specify `KEEP INDEX` or `DROP INDEX` to indicate whether Oracle Database should preserve or drop the index it has been using to enforce the `PRIMARY KEY` or `UNIQUE` constraint.

**ONLINE**

Specify `ONLINE` to indicate that DML operations on the table will be allowed while dropping the constraint.

### Restrictions on Dropping Constraints

Dropping constraints is subject to the following restrictions:

- You cannot drop a primary key or unique key constraint that is part of a referential integrity constraint without also dropping the foreign key. To drop the referenced key and the foreign key together, use the `CASCADE` clause. If you omit `CASCADE`, then Oracle Database does not drop the primary key or unique constraint if any foreign key references it.
- You cannot drop a primary key constraint (even with the `CASCADE` clause) on a table that uses the primary key as its object identifier (OID).
- If you drop a referential integrity constraint on a `REF` column, then the `REF` column remains scoped to the referenced table.
- You cannot drop the scope of a `REF` column.
- You cannot drop the `NOT NULL` constraint on a foreign key column of a reference-partitioned table, and you cannot drop a partitioning referential constraint of a reference-partitioned table.
- You cannot drop the `NOT NULL` constraint on a column that is defined with a default column value using the `ON NULL` clause.
- You cannot specify the `ONLINE` clause when dropping a `DEFERRABLE` constraint.

#### See Also:

["Dropping Constraints: Examples"](#)

### `alter_external_table`

Use the `alter_external_table` clauses to change the characteristics of an external table. This clause has no affect on the external data itself. The syntax and semantics of the `parallel_clause`, `enable_disable_clause`, `external_table_data_props`, and `REJECT LIMIT clause` are the same as described for `CREATE TABLE`. See the [external\\_table\\_clause](#) (in `CREATE TABLE`).

### PROJECT COLUMN Clause

This clause lets you determine how the access driver validates the rows of an external table in subsequent queries. The default is `PROJECT COLUMN ALL`, which means that the access driver processes all column values, regardless of which columns are selected, and validates only those rows with fully valid column entries. If any column value would raise an error, such as a data type conversion error, then the row is rejected even if that column was not referenced in the select list. If you specify `PROJECT COLUMN REFERENCED`, then the access driver processes only those columns in the select list.

The `ALL` setting guarantees consistent result sets. The `REFERENCED` setting can result in different numbers of rows returned, depending on the columns referenced in subsequent queries, but is faster than the `ALL` setting. If a subsequent query selects all columns of the external table, then the settings behave identically.

## Restrictions on Altering External Tables

Altering external tables is subject to the following restrictions:

- You cannot modify an external table using any clause outside of this clause.
- You cannot add a LONG, varray, or object type column to an external table, nor can you change the data type of an external table column to any of these data types.
- You cannot modify the storage parameters of an external table.

### *alter\_table\_partitioning*

The clauses in this section apply only to partitioned tables. You cannot combine partition operations with other partition operations or with operations on the base table in the same ALTER TABLE statement.

## Notes on Changing Table Partitioning

The following notes apply when changing table partitioning:

- If you drop, exchange, truncate, move, modify, or split a partition on a table that is a master table for one or more materialized views, then existing bulk load information about the table will be deleted. Therefore, be sure to refresh all dependent materialized views before performing any of these operations.
- If a bitmap join index is defined on *table*, then any operation that alters a partition of *table* causes Oracle Database to mark the index UNUSABLE.
- The only *alter\_table\_partitioning* clauses you can specify for a reference-partitioned table are *modify\_table\_defaultAttrs*, *move\_table\_[sub]partition*, *truncate\_partition\_subpart*, and *exchange\_partition\_subpart*. None of these operations cascade to any child table of the reference-partitioned table. No other partition maintenance operations are valid on a reference-partitioned table, but you can specify the other partition maintenance operations on the parent table of a reference-partitioned table, and the operation will cascade to the child reference-partitioned table.
- When adding partitions and subpartitions, bear in mind that you can specify up to a total of 1024K-1 partitions and subpartitions for each table.
- When you add a table partition or subpartition and you omit the partition name, the database generates a name using the rules described in "[Notes on Partitioning in General](#)".
- When you move, add (hash only), coalesce, drop, split, merge, rename, or truncate a table partition or subpartition, the procedures, functions, packages, package bodies, views, type bodies, and triggers that reference the table remain valid. All other dependent objects are invalidated.
- Deferred segment creation is not supported for partition maintenance operations that create new segments on tables with LOB columns; segments will always be created for the involved (sub)partitions.
- For sharded tables, the only clauses you can specify for modifying table partitions and subpartitions are UNUSABLE LOCAL INDEXES and REBUILD UNUSABLE LOCAL INDEXES. You cannot perform any other modifications for individual partitions and subpartitions on a system sharded table.
- For user-defined sharded tables the following operations on partitions and subpartitions are supported:

- add partition, add subpartition
- drop partition, drop subpartition
- split partition
- modify partition to add or drop values to a list partition
- For sharded tables, the only supported partition maintenance operations are truncating partitions and subpartitions. You cannot perform any other partition maintenance operations on a sharded table.

For additional information on partition operations on tables with an associated `CONTEXT` domain index, refer to *Oracle Text Reference*.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to *Oracle Database VLDB and Partitioning Guide* for a discussion of these restrictions.

#### ***modify\_table\_defaultAttrs***

The `modify_table_defaultAttrs` clause lets you specify new default values for the attributes of `table`. Only attributes named in the statement are affected. Partitions and LOB partitions you create subsequently will inherit these values unless you override them explicitly when creating the partition or LOB partition. Existing partitions and LOB partitions are not affected by this clause.

Only attributes named in the statement are affected, and the default values specified are overridden by any attributes specified at the individual partition or LOB partition level.

- `FOR partition_extended_name` applies only to composite-partitioned tables. This clause specifies new default values for the attributes of the partition identified in `partition_extended_name`. Subpartitions and LOB subpartitions of that partition that you create subsequently will inherit these values unless you override them explicitly when creating the subpartition or LOB subpartition. Existing subpartitions are not affected by this clause.

If you are modifying the default directory, you can save its location using `DEFAULT DIRECTORY directory`.

- `PCTTHRESHOLD`, `prefix_compression`, and the `alter_overflow_clause` are valid only for partitioned index-organized tables.
- You can specify the `prefix_compression` clause only if prefix compression is already specified at the table level. Further, you cannot specify an integer after the `COMPRESS` keyword. Prefix length can be specified only when you create the table.
- You cannot specify the `PECTUSED` parameter in `segment_attributes` for the index segment of an index-organized table.
- The `read_only_clause` lets you modify the default read-only or read/write mode for the table. The new default mode will be assigned to partitions or subpartitions that are subsequently added to the table, unless you override this behavior by specifying the mode for the new partition or subpartition. When you modify the default read-only or read/write mode of a table, you do not change the mode of the existing partitions and subpartitions in the table. Refer to the `read_only_clause` of `CREATE TABLE` for the full semantics of this clause.
- The `indexing_clause` lets you modify the default indexing property for the table. The new default indexing property will be assigned to partitions or subpartitions that are subsequently added to the table, unless you override this behavior by specifying the

indexing property for the new partition or subpartition. When you modify the default indexing property of a table, you do not change the indexing property of the existing partitions and subpartitions in the table. Refer to the [indexing\\_clause](#) of CREATE TABLE for the full semantics of this clause.

#### ***alter\_automatic\_partitioning***

This clause allows you to manage automatic list-partitioned tables, as follows:

- Use the SET PARTITIONING AUTOMATIC clause to convert a regular list-partitioned table to an automatic list-partitioned table.
- Use the SET PARTITIONING MANUAL clause to convert an automatic list-partitioned table to a regular list-partitioned table.
- You can specify the SET STORE IN clause only for automatic list-partitioned tables. It lets you specify one or more tablespaces into which the database will store data for any subsequent automatically created list partitions. This clause overrides any tablespaces that might have been set for the table by a previously issued SET STORE IN clause.

To determine whether an existing table is an automatic list-partitioned table, you can query the AUTOLIST column of the USER\_, DBA\_, ALL\_PART\_TABLES data dictionary views.

#### ***Restriction on alter\_automatic\_partitioning***

You cannot convert a regular list-partitioned table that contains a DEFAULT partition to an automatic list-partitioned table.

#### **See Also:**

The [AUTOMATIC](#) clause in the documentation on CREATE TABLE for more information on automatic list-partitioned tables

#### ***alter\_interval\_partitioning***

Use this clause:

- To convert an existing range-partitioned table to interval partitioning. The database automatically creates partitions of the specified numeric range or datetime interval as needed for data beyond the highest value allowed for the last range partition. If the table has reference-partitioned child tables, then the child tables are converted to interval reference-partitioned child tables.
- To change the interval of an existing interval-partitioned table. The database first converts existing interval partitions to range partitions and determines the high value of the defined range partitions. The database then automatically creates partitions of the specified numeric range or datetime interval as needed for data that is beyond that high value.
- To change the tablespace storage for an existing interval-partitioned table. If the table has interval reference-partitioned child tables, then the new tablespace storage is inherited by any child table that does not have its own table-level default tablespace.

- To change an interval-partitioned table back to a range-partitioned table. Use `SET INTERVAL ()` to disable interval partitioning. The database converts existing interval partitions to range partitions, using the higher boundaries of created interval partitions as upper boundaries for the range partitions to be created. If the table has interval reference-partitioned child tables, then the child tables are converted to ordinary reference-partitioned child tables.

For `expr`, specify a valid number or interval expression.

#### See Also:

The [CREATE TABLE "INTERVAL Clause"](#) and [Oracle Database VLDB and Partitioning Guide](#) for more information on interval partitioning

### **`set_subpartition_template`**

Use the `set_subpartition_template` clause to create or replace existing default range, list, or hash subpartition definitions for each table partition. This clause is valid only for composite-partitioned tables. It replaces the existing subpartition template or creates a new template if you have not previously created one. Existing subpartitions are not affected, nor are existing local and global indexes. However, subsequent partitioning operations (such as add and merge operations) will use the new template.

You can drop an existing subpartition template by specifying `ALTER TABLE table SET SUBPARTITION TEMPLATE ()`.

The `set_subpartition_template` clause has the same semantics as the `subpartition_template` clause of `CREATE TABLE`. Refer to the [subpartition\\_template](#) clause of `CREATE TABLE` for more information.

### **`modify_table_partition`**

The `modify_table_partition` clause lets you change the real physical attributes of a range, hash, list partition, or system partition. This clause optionally modifies the storage attributes of one or more LOB items for the partition. You can specify new values for physical attributes (with some restrictions, as noted in the sections that follow), logging, and storage parameters.

For all types of partitions, you can also specify how Oracle Database should handle local indexes that become unusable as a result of the modification to the partition. See ["UNUSABLE LOCAL INDEXES Clauses"](#).

For partitioned index-organized tables, you can also update the mapping table in conjunction with partition changes. See the [alter\\_mapping\\_table\\_clauses](#).

### **`read_only_clause`**

Use the `read_only_clause` to put a table partition in read-only or read/write mode. Refer to the [read\\_only\\_clause](#) of `CREATE TABLE` for the full semantics of this clause.

### **`indexing_clause`**

Use the `indexing_clause` to modify the indexing property of a table partition. The indexing property determines whether the partition is included in partial indexes on the table. You can specify the `indexing_clause` in the `modify_range_partition`, `modify_hash_partition`, and `modify_list_partition` clauses.

Specify INDEXING ON to change the indexing property for a table partition to ON. This operation has no effect on full indexes on the table. It has the following effects on partial indexes on the table:

- Local partial indexes: The table partition is included in the index. The corresponding index partition is rebuilt and marked USABLE.
- Global partial indexes: The table partition is included in the index. Index entries for the table partition are added to the index as part of routine index maintenance.

Specify INDEXING OFF to change the indexing property for a table partition to OFF. This operation has no effect on full indexes on the table. It has the following effects on partial indexes on the table:

- Local partial indexes: The table partition is excluded from the index. The corresponding index partition is marked UNUSABLE.
- Global partial indexes: The table partition is excluded from the index. Index entries for the table partition are removed from the index. This is a metadata-only operation and the index entries will continue to be physically stored in the index. You can remove these orphaned index entries by specifying COALESCE CLEANUP in the [ALTER INDEX](#) statement or in the [modify\\_index\\_partition](#) clause.

#### Restriction on column of type object

You cannot partition a table that has an object type. The alter table modification to a partitioned state is only supported for non-partitioned heap tables with zero columns of type object.

#### Restriction on the *indexing\_clause*

You can specify this clause only for partitions of a simple partitioned table. For composite-partitioned tables, you can specify the *indexing\_clause* at the table subpartition level. Refer to [modify\\_table\\_subpartition](#) for more information.

#### Notes on Modifying Table Partitions

The following notes apply to operations on range, list, and hash table partitions:

- For all types of table partition, in the *partition\_attributes* clause, the *shrink\_clause* lets you compact an individual partition segment. Refer to [shrink\\_clause](#) for additional information on this clause.
- The syntax and semantics for modifying a system partition are the same as those for modifying a hash partition. Refer to [modify\\_hash\\_partition](#).
- If *table* is composite partitioned, then:
  - If you specify the *allocate\_extent\_clause*, then Oracle Database allocates an extent for each subpartition of *partition*.
  - If you specify the *deallocate\_unused\_clause*, then Oracle Database deallocates unused storage from each subpartition of *partition*.
  - Any other attributes changed in this clause will be changed in subpartitions of *partition* as well, overriding existing values. To avoid changing the attributes of existing subpartitions, use the FOR PARTITION clause of [modify\\_table\\_defaultAttrs](#).
- When you modify the *partition\_attributes* of a table partition with equipartitioned nested tables, the changes do not apply to the nested table partitions corresponding to the table partition being modified. However, you can

modify the storage table of the nested table partition directly with an ALTER TABLE statement.

- Unless otherwise documented, the remaining clauses of *partition\_attributes* have the same behavior they have when you are creating a partitioned table. Refer to the CREATE TABLE [table\\_partitioning\\_clauses](#) for more information.

#### See Also:

["Modifying Table Partitions: Examples"](#)

### ***modify\_range\_partition***

Use this clause to modify the characteristics of a range partition.

### ***add\_range\_subpartition***

This clause is valid only for range-range composite partitions. It lets you add one or more range subpartitions to *partition*.

Starting with Oracle Database 12c Release 2 (12.2), you can use this clause to add a subpartition to composite-partitioned external table. In this case, you can specify the optional *external\_part\_subpart\_data\_props* clause of the *range\_subpartition\_desc* clause. Refer to [external\\_part\\_subpart\\_data\\_props](#) for the full semantics of this clause.

#### **Restriction on Adding Range Subpartitions**

If *table* is an index-organized table, then you can add only one range subpartition at a time.

### ***add\_hash\_subpartition***

This clause is valid only for range-hash composite partitions. The *add\_hash\_subpartition* clause lets you add a hash subpartition to *partition*. Oracle Database populates the new subpartition with rows rehashed from the other subpartition(s) of *partition* as determined by the hash function. For optimal load balancing, the total number of subpartitions should be a power of 2.

In the *partitioning\_storage\_clause*, the only clause you can specify for subpartitions is the TABLESPACE clause. If you do not specify TABLESPACE, then the new subpartition will reside in the default tablespace of *partition*.

Oracle Database adds local index partitions corresponding to the selected partition.

Oracle Database marks UNUSABLE the local index partitions corresponding to the added partitions. The database invalidates any indexes on heap-organized tables. You can update these indexes during this operation using the [update\\_index\\_clauses](#).

### ***add\_list\_subpartition***

This clause is valid only for range-list and list-list composite partitions. It lets you add one or more list subpartitions to *partition*, and only if you have not already created a DEFAULT subpartition.

- The *list\_values\_clause* is required in this operation, and the values you specify in the *list\_values\_clause* cannot exist in any other subpartition of *partition*. However, these values can duplicate values found in subpartitions of other partitions.

- In the *partitioning\_storage\_clause*, the only clauses you can specify for subpartitions are the TABLESPACE clause and table compression.
- Starting with Oracle Database 12c Release 2 (12.2), you can use this clause to add a subpartition to composite-partitioned external table. In this case, you can specify the optional *external\_part\_subpart\_data\_props* clause of the *list\_subpartition\_desc* clause. Refer to [external\\_part\\_subpart\\_data\\_props](#) for the full semantics of this clause.

For each added subpartition, Oracle Database also adds a subpartition with the same value list to all local index partitions of the table. The status of existing local and global index partitions of *table* are not affected.

### Restrictions on Adding List Subpartitions

The following restrictions apply to adding list subpartitions:

- You cannot specify this clause if you have already created a DEFAULT subpartition for this partition. Instead you must split the DEFAULT partition using the *split\_list\_subpartition* clause.
- If *table* is an index-organized table, then you can add only one list subpartition at a time.

### *coalesce\_table\_subpartition*

COALESCE SUBPARTITION applies only to hash subpartitions. Use the COALESCE SUBPARTITION clause if you want Oracle Database to select the last hash subpartition, distribute its contents into one or more remaining subpartitions (determined by the hash function), and then drop the last subpartition.

- Oracle Database drops local index partitions corresponding to the selected partition.
- Oracle Database marks UNUSABLE the local index partitions corresponding to one or more absorbing partitions. The database invalidates any global indexes on heap-organized tables. You can update these indexes during this operation using the [update\\_index\\_clauses](#).

### *modify\_hash\_partition*

When modifying a hash partition, in the *partition\_attributes* clause, you can specify only the *allocate\_extent\_clause* and *deallocate\_unused\_clause*. All other attributes of the partition are inherited from the table-level defaults except TABLESPACE, which stays the same as it was at create time.

### *modify\_list\_partition*

Clauses available to you when modifying a list partition have the same semantics as when you are modifying a range partition. When modifying a list partition, the following additional clauses are available:

#### ADD | DROP VALUES Clauses

These clauses are valid only when you are modifying composite partitions. Local and global indexes on the table are not affected by either of these clauses.

- Use the ADD VALUES clause to extend the *partition\_key\_value* list of *partition* to include additional values. The added partition values must comply with all rules and restrictions listed in the CREATE TABLE clause [list\\_partitions](#).
- Use the DROP VALUES clause to reduce the *partition\_key\_value* list of *partition* by eliminating one or more *partition\_key\_value*. When you specify this clause, Oracle Database checks to ensure that no rows with this value exist. If such rows do exist, then Oracle Database returns an error.

 **Note:**

ADD VALUES and DROP VALUES operations on a table with a DEFAULT list partition are enhanced if you have defined a local prefixed index on the table.

### Restrictions on Adding and Dropping List Values

Adding and dropping list values are subject to the following restrictions:

- You cannot add values to or drop values from a DEFAULT list partition.
- If *table* contains a DEFAULT partition and you attempt to add values to a nondefault partition, then Oracle Database will check that the values being added do not already exist in the DEFAULT partition. If the values do exist in the DEFAULT partition, then Oracle Database returns an error.

### *modify\_table\_subpartition*

This clause applies only to composite-partitioned tables. Its subclauses let you modify the characteristics of an individual range, list, or hash subpartition.

The *shrink\_clause* lets you compact an individual subpartition segment. Refer to [shrink\\_clause](#) for additional information on this clause.

You can also specify how Oracle Database should handle local indexes that become unusable as a result of the modification to the partition. See "[UNUSABLE LOCAL INDEXES Clauses](#)".

Use the *read\_only\_clause* to put a table subpartition in read-only or read/write mode. Refer to the [read\\_only\\_clause](#) of CREATE TABLE for the full semantics of this clause.

Use the *indexing\_clause* to modify the indexing property of a table subpartition. The indexing property determines whether the subpartition is included in partial indexes on the table. Modifying the indexing property of table subpartitions has the same effect on index subpartitions as modifying the indexing property of table partitions has on index partitions. Refer to the [indexing\\_clause](#) of *modify\_table\_partition* for details.

### Restriction on Modifying Hash Subpartitions

The only *modifyLOB\_parameters* you can specify for *subpartition* are the *allocate\_extent\_clause* and *deallocate\_unused\_clause*.

### ADD | DROP VALUES Clauses

These clauses are valid only when you are modifying list subpartitions. Local and global indexes on the table are not affected by either of these clauses.

- Use the ADD VALUES clause to extend the *subpartition\_key\_value* list of *subpartition* to include additional values. The added partition values must comply with all rules and restrictions listed in the CREATE TABLE clause *list\_partitions*.
- Use the DROP VALUES clause to reduce the *subpartition\_key\_value* list of *subpartition* by eliminating one or more *subpartition\_key\_value*. When you specify this clause, Oracle Database checks to ensure that no rows with this value exist. If such rows do exist, then Oracle Database returns an error.

You can also specify how Oracle Database should handle local indexes that become unusable as a result of the modification to the partition. See "["UNUSABLE LOCAL INDEXES Clauses"](#)".

### Restriction on Modifying List Subpartitions

The only *modify\_LOB\_parameters* you can specify for *subpartition* are the *allocate\_extent\_clause* and *deallocate\_unused\_clause*.

#### *move\_table\_partition*

Use the *move\_table\_partition* clause to move *partition* to another segment. You can move partition data to another tablespace, recluster data to reduce fragmentation, or change create-time physical attributes.

If the table contains LOB columns, then you can use the *LOB\_storage\_clause* to move the LOB data and LOB index segments associated with this partition. Only the LOBs named are affected. If you do not specify the *LOB\_storage\_clause* for a particular LOB column, then its LOB data and LOB index segments are not moved.

If the table contains nested table columns, then you can use the *nested\_table\_col\_properties\_clause* of the *table\_partition\_description* to move the nested table segments associated with this partition. Only the nested table items named are affected. If you do not specify the *nested\_table\_col\_properties\_clause* of the *table\_partition\_description* for a particular nested table column, then its segments are not moved.

Oracle Database moves local index partitions corresponding to the specified partition. If the moved partitions are not empty, then the database marks them UNUSABLE. The database invalidates global indexes on heap-organized tables. You can update these indexes during this operation using the *update\_index\_clauses*.

When you move a LOB data segment, Oracle Database drops the old data segment and corresponding index segment and creates new segments even if you do not specify a new tablespace.

The move operation obtains its parallel attribute from the *parallel\_clause*, if specified. When it is not specified, the default parallel attributes of the table, if any, are used. If neither is specified, then Oracle Database performs the move serially.

Specifying the *parallel\_clause* in MOVE PARTITION does not change the default parallel attributes of *table*.

**Note:**

For index-organized tables, Oracle Database uses the address of the primary key, as well as its value, to construct logical rowids. The logical rowids are stored in the secondary index of the table. If you move a partition of an index-organized table, then the address portion of the rowids will change, which can hamper performance. To ensure optimal performance, rebuild the secondary index(es) on the moved partition to update the rowids.

**See Also:**

"[Moving Table Partitions: Example](#)"

**MAPPING TABLE**

The `MAPPING TABLE` clause is relevant only for an index-organized table that already has a mapping table defined for it. Oracle Database moves the mapping table along with the moved index-organized table partition. The mapping table partition inherits the physical attributes of the moved index-organized table partition. This is the only way you can change the attributes of the mapping table partition. If you omit this clause, then the mapping table partition retains its original attributes.

Oracle Database marks `UNUSABLE` all corresponding bitmap index partitions.

Refer to the [`mapping\_table\_clauses`](#) (in `CREATE TABLE`) for more information on this clause.

**ONLINE**

Specify `ONLINE` to indicate that DML operations on the table partition will be allowed while moving the table partition.

**Restrictions on the ONLINE Clause**

The `ONLINE` clause is subject to the following restrictions when moving table partitions:

- You cannot specify the `ONLINE` clause for tables owned by `SYS`.
- You cannot specify the `ONLINE` clause for index-organized tables.
- You cannot specify the `ONLINE` clause for heap-organized tables that contain object types or on which bitmap join indexes or domain indexes are defined.
- Parallel DML and direct path `INSERT` operations require an exclusive lock on the table. Therefore, these operations are not supported concurrently with an ongoing online partition `MOVE`, due to conflicting locks.

**Restrictions on Moving Table Partitions**

Moving table partitions is subject to the following restrictions:

- If `partition` is a hash partition, then the only attribute you can specify in this clause is `TABLESPACE`.
- You cannot specify this clause for a partition containing subpartitions. However, you can move subpartitions using the `move_table_subpartition` clause.

***move\_table\_subpartition***

Use the *move\_table\_subpartition* clause to move the subpartition identified by *subpartition\_extended\_name* to another segment. If you do not specify TABLESPACE, then the subpartition remains in the same tablespace.

If the subpartition is not empty, then Oracle Database marks UNUSABLE all local index subpartitions corresponding to the subpartition being moved. You can update all indexes on heap-organized tables during this operation using the [update\\_index\\_clauses](#).

If the table contains LOB columns, then you can use the *LOB\_storage\_clause* to move the LOB data and LOB index segments associated with this subpartition. Only the LOBs specified are affected. If you do not specify the *LOB\_storage\_clause* for a particular LOB column, then its LOB data and LOB index segments are not moved.

When you move a LOB data segment, Oracle Database drops the old data segment and corresponding index segment and creates new segments even if you do not specify a new tablespace.

**ONLINE**

Specify ONLINE to indicate that DML operations on the table subpartition will be allowed while moving the table subpartition.

**Restrictions on the ONLINE Clause**

The ONLINE clause for moving table subpartitions is subject to the same restrictions as the ONLINE clause for moving table partitions. Refer to "["Restrictions on the ONLINE Clause."](#)"

**Restriction on Moving Table Subpartitions**

The only clauses of the *partitioning\_storage\_clause* you can specify are the TABLESPACE clause and *table\_compression*.

***add\_external\_partition\_attrs***

Use this clause to add external parameters to a partitioned table.

***add\_table\_partition***

Use the *add\_table\_partition* clause to add one or more range, list, or system partitions to *table*, or to add one hash partition to *table*.

For each partition added, Oracle Database adds to any local index defined on *table* a new partition with the same name as that of the base table partition. If the index already has a partition with such a name, then Oracle Database generates a partition name of the form *SYS\_Pn*.

If *table* is index organized, then for each partition added Oracle Database adds a partition to any mapping table and overflow area defined on the table as well.

If *table* is the parent table of a reference-partitioned table, then you can use the *dependent\_tables\_clause* to propagate the partition maintenance operation you are specifying in this statement to all the reference-partitioned child tables.

The default indexing property of *table* is inherited by the new table partition(s). You can override this by setting the indexing property of a list, range, or system partition

using the *indexing\_clause* in the *table\_partition\_description* clause, or a hash partition using the *indexing\_clause* in the *add\_hash\_partition\_clause*.

For each partition added to a composite-partitioned table, Oracle Database adds a new index partition with the same subpartition descriptions to all local indexes defined on *table*. Global indexes defined on *table* are not affected. If you specify the indexing property for the new table partition, then the new subpartitions inherit the indexing property for the partition. Otherwise, the new subpartitions inherit the default indexing property for the table. You can override this by setting the indexing property of a subpartition using the *indexing\_clause* in the *range\_subpartition\_desc*, *individual\_hash\_subparts*, and *list\_subpartition\_desc* clauses.

### BEFORE Clause

You can specify the optional BEFORE clause only when adding system partitions to *table*. This clause lets you specify where the new partition(s) should be added in relation to existing partitions. You cannot split a system partition. Therefore, this clause is useful if you want to divide the contents of one existing partition among multiple new partitions. If you omit this clause, then the database adds the new partition(s) after the existing partitions.

### Restriction on Adding Table Partitions

If *table* is an index-organized table, or if a local domain index is defined on *table*, then you can add only one partition at a time.

#### See Also:

["Adding a Table Partition with a LOB and Nested Table Storage: Examples"](#) and  
["Adding Multiple Partitions to a Table: Example"](#)

### *add\_range\_partition\_clause*

The *add\_range\_partition\_clause* lets you add a new range partition to the high end of a range-partitioned or composite range-partitioned table (after the last existing partition).

If a domain index is defined on *table*, then the index must not be marked IN\_PROGRESS or FAILED.

### Restrictions on Adding Range Partitions

Adding range partitions is subject to the following restrictions:

- If the upper partition bound of each partitioning key in the existing high partition is MAXVALUE, then you cannot add a partition to the table. Instead, use the *split\_table\_partition* clause to add a partition at the beginning or the middle of the table.
- The *prefix\_compression* and OVERFLOW clauses, are valid only for a partitioned index-organized table. You can specify *prefix\_compression* only if prefix compression is enabled at the table level. You can specify OVERFLOW only if the partitioned table already has an overflow segment.
- You cannot specify the PCTUSED parameter for the index segment of an index-organized table.

### *range\_values\_clause*

Specify the upper bound for the new partition. The *value\_list* is a comma-delimited, ordered list of literal values corresponding to the partitioning key columns. The *value\_list* must collate greater than the partition bound for the highest existing partition in the table.

#### ***table\_partition\_description***

Use this clause to specify any create-time physical attributes for the new partition. If the table contains LOB columns, then you can also specify partition-level attributes for one or more LOB items.

#### ***external\_part\_subpart\_data\_props***

Starting with Oracle Database 12c Release 2 (12.2), Oracle supports partitioned and composite-partitioned external tables. When adding a partition to such a table, you can optionally use this clause to specify the `DEFAULT DIRECTORY` and `LOCATION` for the partition. Refer to [DEFAULT DIRECTORY](#) and [LOCATION](#) in the documentation on `CREATE TABLE` for the full semantics of these clauses.

### **Subpartition Descriptions**

These clauses are valid only for composite-partitioned tables. Use the `range_subpartition_desc`, `list_subpartition_desc`, `individual_hash_subparts`, or `hash_subparts_by_quantity` clause as appropriate, if you want to specify subpartitions for the new partition. This clause overrides any subpartition descriptions defined in `subpartition_template` at the table level.

#### ***add\_hash\_partition\_clause***

The `add_hash_partition_clause` lets you add a new hash partition to the high end of a hash-partitioned table. Oracle Database populates the new partition with rows rehashed from other partitions of `table` as determined by the hash function. For optimal load balancing, the total number of partitions should be a power of 2.

You can specify a name for the partition, and optionally a tablespace where it should be stored. If you do not specify a name, then the database assigns a partition name of the form `SYS_Pn`. If you do not specify `TABLESPACE`, then the new partition is stored in the default tablespace of the table. Other attributes are always inherited from table-level defaults.

If this operation causes data to be rehashed among partitions, then the database marks `UNUSABLE` any corresponding local index partitions. You can update all indexes on heap-organized tables during this operation using the [update\\_index\\_clauses](#).

Use the `parallel_clause` to specify whether to parallelize the creation of the new partition.

Use the `read_only_clause` to put a table partition in read-only or read/write mode. Refer to the [read\\_only\\_clause](#) of `CREATE TABLE` for the full semantics of this clause.

Use the `indexing_clause` to specify the indexing property for the partition. If you do not specify this clause, then the partition inherits the default indexing property of `table`.

 See Also:

[CREATE TABLE](#) and *Oracle Database VLDB and Partitioning Guide* for more information on hash partitioning

***add\_list\_partition\_clause***

The *add\_list\_partition\_clause* lets you add a new partition to *table* using a new set of partition values. You can specify any create-time physical attributes for the new partition. If the table contains LOB columns, then you can also specify partition-level attributes for one or more LOB items.

**Restrictions on Adding List Partitions**

You cannot add a list partition if you have already defined a `DEFAULT` partition for the table. Instead, you must use the *split\_table\_partition* clause to split the `DEFAULT` partition.

 See Also:

- [list\\_partitions](#) of CREATE TABLE for more information and restrictions on list partitions
- "Working with Default List Partitions: Example"

***add\_system\_partition\_clause***

Use this clause to add a partition to a system-partitioned table. Oracle Database adds a corresponding index partition to all local indexes defined on the table.

The *table\_partition\_description* lets you specify partition-level attributes of the new partition. The values of any unspecified attributes are inherited from the table-level values.

**Restriction on Adding System Partitions**

You cannot specify the `OVERFLOW` clause when adding a system partition.

 See Also:

The CREATE TABLE clause [system\\_partitioning](#) for more information on system partitions

***coalesce\_table\_partition***

`COALESCE` applies only to hash partitions. Use the *coalesce\_table\_partition* clause to indicate that Oracle Database should select the last hash partition, distribute its contents into one or more remaining partitions as determined by the hash function, and then drop the last partition.

Oracle Database drops local index partitions corresponding to the selected partition. The database marks `UNUSABLE` the local index partitions corresponding to one or more absorbing

partitions. The database invalidates any indexes on heap-organized tables. You can update all indexes during this operation using the [update\\_index\\_clauses](#).

### Restriction on Coalescing Table Partitions

If you update global indexes using the [update\\_all\\_indexes\\_clause](#), then you can specify only the keywords UPDATE INDEXES, not the subclause.

#### ***drop\_external\_partitionAttrs***

Use this clause to drop external parameters in a partitioned table.

#### ***drop\_table\_partition***

The [drop\\_table\\_partition](#) clause removes partitions, and the data in those partitions, from a partitioned table. If you want to drop a partition but keep its data in the table, then you must merge the partition into one of the adjacent partitions.

Starting with Oracle Database 12c Release 2 (12.2), you can use this clause to drop a partition from a partitioned table or composite-partitioned external table.

#### See Also:

[merge\\_table\\_partitions](#)

Use the [partition\\_extended\\_names](#) clause to specify one or more partitions to be dropped. When specifying multiple partitions, you must specify all partitions by name, as shown in the upper branch of the syntax diagram, or all partitions using the FOR clause, as shown in the lower branch of the syntax diagram. You cannot use both types of syntax in one drop operation.

- If *table* has LOB columns, then Oracle Database also drops the LOB data and LOB index partitions and any subpartitions corresponding to the table partition(s) being dropped.
- If *table* has equipartitioned nested table columns, then Oracle Database also drops the nested table partitions corresponding to the table partition(s) being dropped.
- If *table* is index organized and has a mapping table defined on it, then the database drops the corresponding mapping table partition(s) as well.
- Oracle Database drops local index partitions and subpartitions corresponding to the dropped partition(s), even if they are marked UNUSABLE.

You can update indexes on *table* during this operation using the [update\\_index\\_clauses](#). Updates to global indexes are metadata-only and the index entries for records that are dropped by the drop operation will continue to be physically stored in the index. You can remove these orphaned index entries by specifying COALESCE CLEANUP in the [ALTER INDEX](#) statement or in the [modify\\_index\\_partition](#) clause.

If you specify the [parallel\\_clause](#) with the [update\\_index\\_clauses](#), then the database parallelizes the index update, not the drop operation.

If you drop a range partition and later insert a row that would have belonged to the dropped partition, then the database stores the row in the next higher partition.

However, if that partition is the highest partition, then the insert will fail, because the range of values represented by the dropped partition is no longer valid for the table.

### Restrictions on Dropping Table Partitions

Dropping table partitions is subject to the following restrictions:

- You cannot drop a partition of a hash-partitioned table. Instead, use the `coalesce_table_partition` clause.
- You cannot drop all of the partitions in a table. Instead, drop the table.
- If you update global indexes using the `update_all_indexes_clause`, then you can specify only the `UPDATE INDEXES` keywords but not the subclause.
- If `table` is an index-organized table, or if a local domain index is defined on `table`, then you can drop only one partition at a time.
- You cannot drop a partition of a duplicated table.
- Dropping a partition does not place the partition in the Oracle Database recycle bin, regardless of the setting of the recycle bin. Dropped partitions are immediately removed from the system.

#### See Also:

["Dropping a Table Partition: Example"](#)

### `drop_table_subpartition`

Use this clause to drop range or list subpartitions from a range, list, or hash composite-partitioned table. Oracle Database deletes any rows in the dropped subpartition(s).

Starting with Oracle Database 12c Release 2 (12.2), you can use this clause to drop a subpartition from a composite-partitioned external table.

Use the `subpartition_extended_names` clause to specify one or more subpartitions to be dropped. When specifying multiple subpartitions, you must specify all subpartitions by name, as shown in the upper branch of the syntax diagram, or all subpartitions using the `FOR` clause, as shown in the lower branch of the syntax diagram. You cannot use both types of syntax in one drop operation.

Oracle Database drops the corresponding subpartition(s) of any local index. Other index subpartitions are not affected. Any global indexes are marked `UNUSABLE` unless you specify the `update_global_index_clause` or `update_all_indexes_clause`. Updates to global indexes are metadata-only and the index entries for records that are dropped by the drop operation will continue to be physically stored in the index. You can remove these orphaned index entries by specifying `COALESCE CLEANUP` in the `ALTER INDEX` statement or in the `modify_index_partition` clause.

### Restrictions on Dropping Table Subpartitions

Dropping table subpartitions is subject to the following restrictions:

- You cannot drop a hash subpartition. Instead use the `MODIFY PARTITION ... COALESCE SUBPARTITION` syntax.

- You cannot drop all of the subpartitions in a partition. Instead, use the *drop\_table\_partition* clause.
- If you update the global indexes, then you cannot specify the optional subclause of the *update\_all\_indexes\_clause*.
- If *table* is an index-organized table, then you can drop only one subpartition at a time.
- When dropping multiple subpartitions, all of the subpartitions must be in the same partition.
- You cannot drop a subpartition of a duplicated table.

#### ***rename\_partition\_subpart***

Use the *rename\_partition\_subpart* clause to rename a table partition or subpartition to *new\_name*. For both partitions and subpartitions, *new\_name* must be different from all existing partitions and subpartitions of the same table.

If *table* is index organized, then Oracle Database assigns the same name to the corresponding primary key index partition as well as to any existing overflow partitions and mapping table partitions.

Starting with Oracle Database 12c Release 2 (12.2), you can use this clause to rename a partition or subpartition in a partitioned or composite-partitioned external table.

 **See Also:**

["Renaming Table Partitions: Examples"](#)

#### ***truncate\_partition\_subpart***

Specify *TRUNCATE partition\_extended\_names* to remove all rows from the partition(s) identified by *partition\_extended\_names* or, if the table is composite partitioned, all rows from the subpartitions of those partitions. Specify *TRUNCATE subpartition\_extended\_names* to remove all rows from individual subpartitions. If *table* is index organized, then Oracle Database also truncates any corresponding mapping table partitions and overflow area partitions.

When specifying multiple partitions, you must specify all partitions by name, as shown in the upper branch of the *partition\_extended\_names* syntax diagram, or all partitions using the *FOR* clause, as shown in the lower branch of the syntax diagram. You cannot use both types of syntax in one truncate operation. The same rule applies when specifying multiple subpartitions with the *subpartition\_extended\_names* clause.

For each specified partition or subpartition:

- If the partition or subpartition to be truncated contain data, then you must first disable any referential integrity constraints on the table. Alternatively, you can delete the rows and then truncate the partition.
- If *table* contains any LOB columns, then the LOB data and LOB index segments for the partition are also truncated. If *table* is composite partitioned, then the LOB data and LOB index segments for the subpartitions of the partition are truncated.

- If *table* contains any equipartitioned nested tables, then you cannot truncate the parent partition unless its corresponding nested table partition is empty.
- If a domain index is defined on *table*, then the index must not be marked IN\_PROGRESS or FAILED, and the index partition corresponding to the table partition being truncated must not be marked IN\_PROGRESS.

For each partition or subpartition truncated, Oracle Database also truncates corresponding local index partitions and subpartitions. If those index partitions or subpartitions are marked UNUSABLE, then the database truncates them and resets the UNUSABLE marker to VALID.

You can update indexes on *table* during this operation using the [update\\_index\\_clauses](#).

Updates to global indexes are metadata-only and the index entries for records that are dropped by the truncate operation will continue to be physically stored in the index. You can remove these orphaned index entries by specifying COALESCE CLEANUP in the [ALTER INDEX](#) statement or in the [modify\\_index\\_partition](#) clause.

If you specify the *parallel\_clause* with the *update\_index\_clauses*, then the database parallelizes the index update, not the truncate operation.

#### DROP STORAGE

Specify DROP STORAGE to deallocate all space from the deleted rows, except the space allocated by the MINEXTENTS parameter. This space can subsequently be used by other objects in the tablespace.

#### DROP ALL STORAGE

Specify DROP ALL STORAGE to deallocate all space from the deleted rows, including the space allocated by the MINEXTENTS parameter. All segments for the partition(s) or subpartition(s), as well as all segments for their dependent objects, will be deallocated.

#### Restrictions on DROP ALL STORAGE

This clause is subject to the same restrictions as described in "[Restrictions on Deferred Segment Creation](#)".

#### REUSE STORAGE

Specify REUSE STORAGE to keep space from the deleted rows allocated to the partition(s) or subpartition(s). The space is subsequently available only for inserts and updates to the same partition(s) or subpartition(s).

#### CASCADE

Specify CASCADE to truncate the corresponding partition(s) or subpartition(s) in all reference-partitioned child tables of *table*.

#### Restrictions on Truncating Table Partitions and Subpartitions

Truncating table partitions and subpartitions is subject to the following restrictions:

- If you update global indexes using the *update\_all\_indexes\_clause*, then you can specify only the UPDATE INDEXES keywords, not the subclause.
- If *table* is an index-organized table, or if a local domain index is defined on *table*, then you can truncate only one table partition or one table subpartition at a time.
- You cannot truncate partitions or subpartitions in a duplicated table.

 See Also:

["Truncating Table Partitions: Example"](#)

***split\_table\_partition***

The *split\_table\_partition* clause lets you create, from the partition identified by *partition\_extended\_name*, multiple new partitions, each with a new segment, new physical attributes, and new initial extents. The segment associated with the current partition is discarded.

The new partitions inherit all unspecified physical attributes from the current partition.

 Note:

Oracle Database can optimize and speed up SPLIT PARTITION and SPLIT SUBPARTITION operations if specific conditions are met. Refer to *Oracle Database VLDB and Partitioning Guide* for information on optimizing these operations.

- If you split a DEFAULT list partition, then the last resulting partition will have the DEFAULT value. All other resulting partitions will have the specified split values.
- If *table* is index organized, then Oracle Database splits any corresponding mapping table partition and places it in the same tablespace as the parent index-organized table partition. The database also splits any corresponding overflow area, and you can use the OVERFLOW clause to specify segment attributes for the new overflow areas.
- If *table* contains LOB columns, then you can use the *LOB\_storage\_clause* to specify separate LOB storage attributes for the LOB data segments resulting from the split. The database drops the LOB data and LOB index segments of the current partition and creates new segments for each LOB column, for each partition, even if you do not specify a new tablespace.
- If *table* contains nested table columns, then you can use the *split\_nested\_table\_part* clause to specify the storage table names and segment attributes of the nested table segments resulting from the split. The database drops the nested table segments of the current partition and creates new segments for each nested table column, for each partition. This clause allows for multiple nested table columns in the parent table as well as multilevel nested table columns.

Oracle Database splits the corresponding local index partition, even if it is marked UNUSABLE. The database marks UNUSABLE, and you must rebuild the local index partitions corresponding to the split partitions. The new index partitions inherit their attributes from the partition being split. The database stores the new index partitions in the default tablespace of the index partition being split. If that index partition has no default tablespace, then the database uses the tablespace of the new underlying table partitions.

**AT Clause**

The `AT` clause applies only to range partitions and lets you split one range partition into two range partitions. Specify the new noninclusive upper bound for the first of the two new partitions. The value list must compare less than the original partition bound for the current partition and greater than the partition bound for the next lowest partition (if there is one).

### VALUES Clause

The `VALUES` clause applies only to list partitions and allows you to split one list partition into two list partitions. If the table is partitioned on one key column, then use the upper branch of the `list_values` syntax to specify a list of values for that column. You can specify `NULL` if you have not already specified `NULL` for another partition in the table. If the table is partitioned on multiple key columns, then use the lower branch of the `list_values` syntax to specify a list of value lists. Each value list is enclosed in parentheses and represents a list of values for the key columns. Oracle Database creates the first new partition using the `list_values` you specify and creates the second new partition using the remaining partition values from the current partition. Therefore, the value list cannot contain all of the partition values of the current partition, nor can it contain any partition values that do not already exist for the current partition.

### INTO Clause

The `INTO` clause lets you describe the new partitions resulting from the split.

- The `AT ... INTO` clause lets you describe the partitions resulting from splitting one range partition into two range partitions. In `range_partition_desc`, the keyword `PARTITION` is required even if you do not specify the optional names and physical attributes of the two partitions resulting from the split. If you do not specify new partition names, then Oracle Database assigns names of the form `SYS_Pn`. Any attributes you do not specify are inherited from the current partition.
- The `VALUES ... INTO` clause lets you describe the partitions resulting from splitting one list partition into two list partitions. In `list_partition_desc`, the keyword `PARTITION` is required even if you do not specify the optional names and physical attributes of the two partitions resulting from the split. If you do not specify new partition names, then Oracle Database assigns names of the form `SYS_Pn`. Any attributes you do not specify are inherited from the current partition.
- The `INTO` clause lets you split one range partition into two or more range partitions, or one list partition into two or more list partitions. If you do not specify new partition names, then Oracle Database assigns names of the form `SYS_Pn`. Any attributes you do not specify are inherited from the current partition.
  - You must specify range partitions in ascending order of their partition bounds. The partition bound of the first specified range partition must be greater than the partition bound for the next lowest partition in the table (if there is one). Do not specify a partition bound for the last range partition; it will inherit the partition bound of the current partition.
  - For list partitions, all specified partition values for the new partitions must exist in the current partition. Do not specify any partition values for the last partition. Oracle Database creates the last partition using the remaining partition values from the current partition.

For range-hash composite-partitioned tables, if you specify subpartitioning for the new partitions, then you can specify only `TABLESPACE` and table compression for the subpartitions. All other attributes are inherited from the current partition. If you do not specify subpartitioning for the new partitions, then their tablespace is also inherited from the current partition.

For range-list and list-list composite-partitioned tables, you cannot specify subpartitions for the new partitions at all. The list subpartitions of the split partition inherit the number of subpartitions and value lists from the current partition.

For all composite-partitioned tables for which you do not specify subpartition names for the newly created subpartitions, the newly created subpartitions inherit their names from the parent partition as follows:

- For those subpartitions in the parent partition with names of the form `partition_name underscore (_) subpartition_name` (for example, `P1_SUBP1`), Oracle Database generates corresponding names in the newly created subpartitions using the new partition names (for example `P1A_SUB1` and `P1B_SUB1`).
- For those subpartitions in the parent partition with names of any other form, Oracle Database generates subpartition names of the form `SYS_SUBPn`.

Oracle Database splits the corresponding partition(s) in each local index defined on `table`, even if the index is marked `UNUSABLE`.

If `table` is the parent table of a reference-partitioned table, then you can use the `dependent_tables_clause` to propagate the partition maintenance operation you are specifying in this statement to all the reference-partitioned child tables.

Oracle Database invalidates any indexes on heap-organized tables. You can update these indexes during this operation using the [update\\_index\\_clauses](#).

The `parallel_clause` lets you parallelize the split operation but does not change the default parallel attributes of the table.

## ONLINE

Specify `ONLINE` to indicate that DML operations on the table will be allowed while splitting the table partition.

### Restrictions on the ONLINE Clause

The `ONLINE` clause is subject to the following restrictions when splitting table partitions:

- You cannot specify the `ONLINE` clause for tables owned by `SYS`.
- You cannot specify the `ONLINE` clause for index-organized tables.
- You cannot specify the `ONLINE` clause if a domain index is defined on the table.
- You cannot specify the `ONLINE` clause for heap-organized tables that contain object types or on which bitmap join indexes are defined.
- Parallel DML and direct path `INSERT` operations require an exclusive lock on the table. Therefore, these operations are not supported concurrently with an ongoing online partition split, due to conflicting locks.

### Restrictions on Splitting Table Partitions

Splitting table partitions is subject to the following restrictions:

- You cannot specify this clause for a hash partition.
- You cannot specify the `parallel_clause` for index-organized tables.
- If `table` is an index-organized table, or if a local domain index is defined on `table`, then you can split the partition into only two new partitions.

 See Also:

"[Splitting Table Partitions: Examples](#)"

***split\_table\_subpartition***

Use this clause to split a subpartition into multiple new subpartitions with nonoverlapping value lists.

 Note:

Oracle Database can optimize and speed up `SPLIT PARTITION` and `SPLIT SUBPARTITION` operations if specific conditions are met. Refer to *Oracle Database VLDB and Partitioning Guide* for information on optimizing these operations.

**AT Clause**

The `AT` clause is valid only for range subpartitions. Specify the new noninclusive upper bound for the first of the two new subpartitions. The value list must compare less than the original subpartition bound for the subpartition identified by `subpartition_extended_name` and greater than the partition bound for the next lowest subpartition (if there is one).

**VALUES Clause**

The `VALUES` clause is valid only for list subpartitions. If the table is subpartitioned on one key column, then use the upper branch of the `list_values` syntax to specify a list of values for that column. You can specify `NULL` if you have not already specified `NULL` for another subpartition in the same partition. If the table is subpartitioned on multiple key columns, then use the lower branch of the `list_values` syntax to specify a list of value lists. Each value list is enclosed in parentheses and represents a list of values for the key columns. Oracle Database creates the first new subpartition using the subpartition value list you specify and creates the second new partition using the remaining partition values from the current subpartition. Therefore, the value list cannot contain all of the partition values of the current subpartition, nor can it contain any partition values that do not already exist for the current subpartition.

**INTO Clause**

The `INTO` clause lets you describe the new subpartitions resulting from the split.

- The `AT ... INTO` clause lets you describe the two subpartitions resulting from splitting one range partition into two range partitions. In `range_subpartition_desc`, the keyword `SUBPARTITION` is required even if you do not specify the optional names and attributes of the two new subpartitions. If you do not specify new subpartition names, then Oracle Database assigns names of the form `SYS_SUBPn`. Any attributes you do not specify are inherited from the current subpartition.
- The `VALUES ... INTO` clause lets you describe the two subpartitions resulting from splitting one list partition into two list partitions. In `list_subpartition_desc`, the keyword `SUBPARTITION` is required even if you do not specify the optional names and attributes of the two new subpartitions. If you do not specify new subpartition names, then Oracle

Database assigns names of the form `SYS_SUBPn`. Any attributes you do not specify are inherited from the current subpartition.

- The `INTO` clause lets you split one range subpartition into two or more range subpartitions, or one list subpartition into two or more list subpartitions. If you do not specify new subpartition names, then Oracle Database assigns names of the form `SYS_SUBPn`. Any attributes you do not specify are inherited from the current subpartition.
  - You must specify range subpartitions in ascending order of their subpartition bounds. The subpartition bound of the first specified range subpartition must be greater than the subpartition bound for the next lowest subpartition (if there is one). Do not specify a subpartition bound for the last range subpartition; it will inherit the partition bound of the current subpartition.
  - For list subpartitions, all specified subpartition values for the new subpartitions must exist in the current subpartition. Do not specify any subpartition values for the last subpartition. Oracle Database creates the last subpartition using the remaining partition values from the current subpartition.

Oracle Database splits any corresponding local subpartition index, even if it is marked `UNUSABLE`. The new index subpartitions inherit the names of the new table subpartitions unless those names are already held by index subpartitions. In that case, the database assigns new index subpartition names of the form `SYS_SUBPn`. The new index subpartitions inherit physical attributes from the parent subpartition. However, if the parent subpartition does not have a default `TABLESPACE` attribute, then the new subpartitions inherit the tablespace of the corresponding new table subpartitions.

Oracle Database invalidates indexes on heap-organized tables. You can update these indexes by using the [update\\_index\\_clauses](#).

## ONLINE

Specify `ONLINE` to indicate that DML operations on the table will be allowed while splitting the table subpartition.

### Restrictions on the ONLINE Clause

The `ONLINE` clause for splitting table subpartitions is subject to the same restrictions as the `ONLINE` clause for splitting table partitions. Refer to [Restrictions on the ONLINE Clause](#).

### Restrictions on Splitting Table Subpartitions

Splitting table subpartitions is subject to the following restrictions:

- You cannot specify this clause for a hash subpartition.
- In subpartition descriptions, the only clauses of `partitioning_storage_clause` you can specify are `TABLESPACE` and table compression.
- You cannot specify the `parallel_clause` for index-organized tables.
- If `table` is an index-organized table, then you can split the subpartition into only two new subpartitions.

### `merge_table_partitions`

The `merge_table_partitions` clause lets you merge the contents of two or more range, list, or system partitions of `table` into one new partition and then drop the

original partitions. This clause is not valid for hash partitions. Use the `coalesce_table_partition` clause instead.

Specify a comma-separated list of two or more range, list, or system partitions to be merged. You can use the `TO` clause to specify two or more adjacent range partitions to be merged.

For each partition, use `partition` to specify a partition name or the `FOR` clause to specify a partition without using its name. See "[References to Partitioned Tables and Indexes](#)" for more information on the `FOR` clause.

- The partitions to be merged must be adjacent and must be specified in ascending order of their partition bounds if they are range partitions. List partitions and system partitions need not be adjacent in order to be merged.
- When you merge range partitions, the new partition inherits the partition bound of the highest of the original partitions.
- When you merge list partitions, the resulting partition value list is the union of the set of the partition values lists of the partitions being merged. If you merge a `DEFAULT` list partition with other list partitions, then the resulting partition will be the `DEFAULT` partition and will have the `DEFAULT` value.
- When you merge composite range partitions or composite list partitions, range-list or list-list composite partitions, you cannot specify subpartition descriptions. Oracle Database obtains the subpartitioning information from the subpartition template. If you have not specified a subpartition template, then the database creates one `MAXVALUE` subpartition from range subpartitions or one `DEFAULT` subpartition from list subpartitions.

Any attributes you do not specify explicitly for the new partition are inherited from table-level defaults. However, if you reuse one of the partition names for the new partition, then the new partition inherits values from the partition whose name is being reused rather than from table-level default values.

Oracle Database drops local index partitions corresponding to the selected partitions and marks `UNUSABLE` the local index partition corresponding to merged partition. The database also marks `UNUSABLE` any global indexes on heap-organized tables. You can update all these indexes during this operation using the [`update\_index\_clauses`](#).

If `table` is the parent table of a reference-partitioned table, then you can use the `dependent_tables_clause` to propagate the partition maintenance operation you are specifying in this statement to all the reference-partitioned child tables.

## ONLINE

Specify `ONLINE` to allow DML operations on the table partitions during the merge partitions operation.

### Restriction on Merging Table Partitions

If `table` is an index-organized table, or if a local domain index is defined on `table`, then you can merge only two partitions at a time.

#### See Also:

["Merging Two Table Partitions: Example"](#), ["Merging Four Adjacent Range Partitions: Example"](#), and ["Working with Default List Partitions: Example"](#)

### ***merge\_table\_subpartitions***

The *merge\_table\_subpartitions* clause lets you merge the contents of two or more range or list subpartitions of *table* into one new subpartition and then drop the original subpartitions. This clause is not valid for hash subpartitions. Use the *coalesce\_hash\_subpartition* clause instead.

Specify a comma-separated list of two or more range or list subpartitions to be merged. You can use the *TO* clause to specify two or more adjacent range subpartitions to be merged.

For each subpartition, use *subpartition* to specify a subpartition name or the *FOR* clause to specify a subpartition without using its name. See "[References to Partitioned Tables and Indexes](#)" for more information on the *FOR* clause.

The subpartitions to be merged must belong to the same partition. If they are range subpartitions, then they must be adjacent. If they are list subpartitions, then they need not be adjacent. The data in the resulting subpartition consists of the combined data from the merged subpartitions.

If you specify the *INTO* clause, then in the *range\_subpartition\_desc* or *list\_subpartition\_desc* you cannot specify the *range\_values\_clause* or *list\_values\_clause*, respectively. Further, the only clauses you can specify in the *partitioning\_storage\_clause* are the *TABLESPACE* clause and *table\_compression*.

Any attributes you do not specify explicitly for the new subpartition are inherited from partition-level values. However, if you reuse one of the subpartition names for the new subpartition, then the new subpartition inherits values from the subpartition whose name is being reused rather than from partition-level default values.

Oracle Database merges corresponding local index subpartitions and marks the resulting index subpartition *UNUSABLE*. The database also marks *UNUSABLE* both partitioned and nonpartitioned global indexes on heap-organized tables. You can update all indexes during this operation using the *update\_index\_clauses*.

### **ONLINE**

Specify *ONLINE* to allow DML operations on the table subpartitions during the merge subpartitions operation.

### **Restriction on Merging Table Subpartitions**

If *table* is an index-organized table, then you can merge only two subpartitions at a time.

### ***exchange\_partition\_subpart***

Use the EXCHANGE PARTITION or EXCHANGE SUBPARTITION clause to exchange the data and index segments of:

- One nonpartitioned table with:
  - one range, list, or hash partition
  - one range, list, or hash subpartition
- One range-partitioned table with the range subpartitions of a range-range or list-range composite-partitioned table partition

- One hash-partitioned table with the hash subpartitions of a range-hash or list-hash composite-partitioned table partition
- One list-partitioned table with the list subpartitions of a range-list or hash-list composite-partitioned table partition

In all cases, the structure of the table and the partition or subpartition being exchanged, including their partitioning keys, must be identical. In the case of list partitions and subpartitions, the corresponding value lists must also match.

This clause facilitates high-speed data loading when used with transportable tablespaces.

#### See Also:

*Oracle Database Administrator's Guide* for information on transportable tablespaces

If `table` contains LOB columns, then for each LOB column Oracle Database exchanges LOB data and LOB index partition or subpartition segments with corresponding LOB data and LOB index segments of `table`.

If `table` has nested table columns, then for each such column Oracle Database exchanges nested table partition segments with corresponding nested table segments of the nonpartitioned table.

If `table` contains an identity column, then so must the partition or subpartition being exchanged, and vice versa. The sequence generators must both be increasing or decreasing. The sequence generators are not exchanged, so `table` and the partition or subpartition will continue to use the same sequence generators. The high water mark for both sequence generators will be adjusted so that new identity column values will not conflict with existing values.

All of the segment attributes of the two objects (including tablespace and logging) are also exchanged.

Existing statistics for the table being exchanged into the partitioned table will be exchanged. However, the global statistics for the partitioned table will not be altered. Use the `DBMS_STATS.GATHER_TABLE_STATS` procedure to re-create global statistics. You can set the `GRANULARITY` attribute equal to '`APPROX_GLOBAL AND PARTITION`' to speed up the process and aggregate new global statistics based on the existing partition statistics. See *Oracle Database PL/SQL Packages and Types Reference* for more information on this packaged procedure.

Oracle Database invalidates any global indexes on the objects being exchanged. You can update the global indexes on the table whose partition is being exchanged by using either the `update_global_index_clause` or the `update_all_indexes_clause`. For the `update_all_indexes_clause`, you can specify only the keywords `UPDATE INDEXES`, not the subclause. Global indexes on the table being exchanged remain invalidated. The `update_global_index_clause` and `update_all_indexes_clause` do not update local indexes during an exchange operation. You can specify local index maintenance by using the `INCLUDING | EXCLUDING INDEXES` clause. If you specify the `parallel_clause` with either of these clauses, then the database parallelizes the index update, not the exchange operation.

 See Also:

"[Notes on Exchanging Partitions and Subpartitions](#)"

### WITH TABLE

Specify the *table* with which the partition or subpartition will be exchanged. If you omit *schema*, then Oracle Database assumes that *table* is in your own schema.

### INCLUDING | EXCLUDING INDEXES

Specify **INCLUDING INDEXES** if you want local index partitions or subpartitions to be exchanged with the corresponding table index (for a nonpartitioned table) or local indexes (for a hash-partitioned table). Specify **EXCLUDING INDEXES** if you want all index partitions or subpartitions corresponding to the partition and all the regular indexes and index partitions on the exchanged table to be marked **UNUSABLE**. If you omit this clause, then the default is **EXCLUDING INDEXES**.

### WITH | WITHOUT VALIDATION

Specify **WITH VALIDATION** if you want Oracle Database to return an error if any rows in the exchanged table do not map into partitions or subpartitions being exchanged.

Specify **WITHOUT VALIDATION** if you do not want Oracle Database to check the proper mapping of rows in the exchanged table. If you omit this clause, then the default is **WITH VALIDATION**.

#### *exceptions\_clause*

See "[Handling Constraint Exceptions](#)" for information on this clause. In the context of exchanging partitions, this clause is valid only if the partitioned table has been defined with a **UNIQUE** constraint, and that constraint must be in **DISABLE VALIDATE** state. This clause is valid only for exchanging partition, not subpartitions.

### CASCADE

Specify **CASCADE** to exchange the corresponding partition or subpartition in all reference-partitioned child tables of *table*. The reference-partitioned table hierarchies of the source and target must match.

### Restrictions on CASCADE

The following restrictions apply to the **CASCADE** clause:

- You cannot specify **CASCADE** if a parent key in the reference-partitioned table hierarchy is referenced by multiple partitioning constraints.
- You cannot specify **CASCADE** if a domain index or an **XMLIndex** index is defined on any of the reference-partitioned child tables of *table*.

 See Also:

- The `DBMS_IOT` package in *Oracle Database PL/SQL Packages and Types Reference* for information on the SQL scripts
- *Oracle Database Administrator's Guide* for information on eliminating migrated and chained rows
- `constraint` for more information on constraint checking and "[Creating an Exceptions Table for Index-Organized Tables: Example](#)"

**Notes on Exchanging Partitions and Subpartitions**

The following notes apply when exchanging partitions and subpartitions:

- Both tables involved in the exchange must have the same primary key, and no validated foreign keys can be referencing either of the tables unless the referenced table is empty.
- When exchanging partitioned index-organized tables:
  - The source and target table or partition must have their primary key set on the same columns, in the same order.
  - If prefix compression is enabled, then it must be enabled for both the source and the target, and with the same prefix length.
  - Both the source and target must be index organized.
  - Both the source and target must have overflow segments, or neither can have overflow segments. Also, both the source and target must have mapping tables, or neither can have a mapping table.
  - Both the source and target must have identical storage attributes for any LOB columns.

 See Also:

- "[Exchanging Table Partitions: Example](#)"

**`dependent_tables_clause`**

This clause is valid only when you are altering the parent table of a reference-partitioned table. The clause lets you specify attributes of partitions that are created by the operation for reference-partitioned child tables of the parent table.

- If the parent table is not composite partitioned, then specify one or more child tables, and for each child table specify one `partition_spec` for each partition created in the parent table.
- If the parent table is composite, then specify one or more child tables, and for each child table specify one `partition_spec` for each subpartition created in the parent table.

 **See Also:**

The CREATE TABLE clause [reference\\_partitioning](#) for information on creating reference-partitioned tables and *Oracle Database VLDB and Partitioning Guide* for information on partitioning by reference in general

### UNUSABLE LOCAL INDEXES Clauses

These two clauses modify the attributes of local index partitions and index subpartitions corresponding to *partition*, depending on whether you are modifying a partition or subpartition.

- UNUSABLE LOCAL INDEXES marks UNUSABLE the local index partition or index subpartition associated with *partition*.
- REBUILD UNUSABLE LOCAL INDEXES rebuilds the unusable local index partition or index subpartition associated with *partition*.

### Restrictions on UNUSABLE LOCAL INDEXES

This clause is subject to the following restrictions:

- You cannot specify this clause with any other clauses of the *modify\_table\_partition* clause.
- You cannot specify this clause in the *modify\_table\_partition* clause for a partition that has subpartitions. However, you can specify this clause in the *modify\_table\_subpartition* clause.

### *update\_index\_clauses*

Use the *update\_index\_clauses* to update the indexes on *table* as part of the table partitioning operation. When you perform DDL on a table partition, if an index is defined on *table*, then Oracle Database invalidates the entire index, not just the partitions undergoing DDL. This clause lets you update the index partition you are changing during the DDL operation, eliminating the need to rebuild the index after the DDL.

The *update\_index\_clauses* are not needed, and are not valid, for partitioned index-organized tables. Index-organized tables are primary key based, so Oracle can keep global indexes **USABLE** during operations that move data but do not change its value.

### *update\_global\_index\_clause*

Use this clause to update only global indexes on *table*. Oracle Database marks UNUSABLE all local indexes on *table*.

### UPDATE GLOBAL INDEXES

Specify UPDATE GLOBAL INDEXES to update the global indexes defined on *table*.

### Restriction on Updating Global Indexes

If the global index is a global domain index defined on a LOB column, then Oracle Database marks the domain index **UNUSABLE** instead of updating it.

### INVALIDATE GLOBAL INDEXES

Specify INVALIDATE GLOBAL INDEXES to invalidate the global indexes defined on *table*.

If you specify neither, then Oracle Database invalidates the global indexes.

### Restrictions on Invalidating Global Indexes

This clause is supported only for global indexes. It is not supported for index-organized tables. In addition, this clause updates only indexes that are USABLE and VALID. UNUSABLE indexes are left unusable, and INVALID global indexes are ignored.

#### *update\_all\_indexes\_clause*

Use this clause to update all indexes on *table*.

#### *update\_index\_partition*

This clause is valid only for operations on table partitions and affects only local indexes.

- The *index\_partition\_description* lets you specify physical attributes, tablespace storage, and logging for each partition of each local index. If you specify only the PARTITION keyword, then Oracle Database updates the index partition as follows:
  - For operations on a single table partition (such as MOVE PARTITION and SPLIT PARTITION), the corresponding index partition inherits the attributes of the affected index table partition, Oracle Database does not generate names for new index partitions, so any new index partitions resulting from this operation inherit their names from the corresponding new table partition.
  - For MERGE PARTITION operations, the resulting local index partition inherits its name from the resulting table partition and inherits its attributes from the local index.

For a domain index, you can use the PARAMETERS clause to specify the parameter string that is passed uninterpreted to the appropriate ODCI indextype routine. The PARAMETERS clause is valid only for domain indexes, and is the only part of the *index\_partition\_description* you can specify for a domain index.

#### See Also:

*Oracle Database Data Cartridge Developer's Guide* for more information on domain indexes

- For a composite-partitioned index, the *index\_subpartition\_clause* lets you specify tablespace storage for each subpartition. Refer to the [index\\_subpartition\\_clause](#) (in CREATE INDEX) for more information on this component of the *update\_index\_partition* clause.

For information on the USABLE and UNUSABLE keywords, refer to ALTER INDEX ... [USABLE | UNUSABLE](#).

#### *update\_index\_subpartition*

This clause is valid only for operations on subpartitions of composite-partitioned tables and affects only local indexes on composite-partitioned tables. It lets you specify tablespace storage for one or more subpartitions.

### Restrictions on Updating All Indexes

The following restrictions apply to the *update\_all\_indexes\_clause*:

- You cannot specify this clause for index-organized tables.
- When you exchange a partition or subpartition with the `exchange_partition_subpart` clause, the `update_all_indexes_clause` is applicable only to global indexes. Therefore, you cannot specify the `update_index_partition` or `update_index_subpartition` clauses. You can, however, specify local index maintenance during an exchange operation by using the **INCLUDING | EXCLUDING INDEXES** clause.

 **See Also:**

"[Updating Global Indexes: Example](#)" and "[Updating Partitioned Indexes: Example](#)"

### ***parallel\_clause***

The `parallel_clause` lets you change the default degree of parallelism for queries and DML on the table.

For complete information on this clause, refer to [`parallel\_clause`](#) in the documentation on `CREATE TABLE`.

### **Restrictions on Changing Table Parallelization**

Changing parallelization is subject to the following restrictions:

- If `table` contains any columns of LOB or user-defined object type, then subsequent `INSERT`, `UPDATE`, and `DELETE` operations on `table` are executed serially without notification. Subsequent queries, however, are executed in parallel.
- If you specify the `parallel_clause` in conjunction with the `move_table_clause`, then the parallelism applies only to the move, not to subsequent DML and query operations on the table.

 **See Also:**

"[Specifying Parallel Processing: Example](#)"

### ***alter\_table\_partitionset***

The clauses of `alter_table_partitionset` only apply to sharded tables within a composite sharding setup.

The following notes apply when changing table partitioning of sharded tables:

- Specify `add_partitionset` only to root sharded tables.
- For add and split partitionset operations you must deploy a new primary shardspace per partitionset before specifying `add_partitionset`.
- For add and split partitionset operations partition names do not have a value list after them. This is different from partition by list.

- Specify `modify_partitionset` only to root sharded tables that are partitioned by list.
- You must provide all the partitionset names as these are not generated by the system.

#### ***add\_partitionset***

`add_partitionset` clause is only valid for a root sharded table in a composite sharding setup. When a new primary shardspace is created, `add_partitionset` needs to be used to create new partitionsets.

See [Operations on Directory-Based Partitioned Table](#) for examples.

#### ***modify\_partitionset***

`modify_partitionset` clause is only value for a root sharded table that is partitionset by LIST. Use this clause to add a new list value to an existing partitionset.

#### ***move\_partitionset***

Use `move_partitionset` to move all existing partitions of a sharded table in a partitionset to new tablespace sets.

#### ***filter\_condition***

This clause lets you specify which rows to preserve during the following ALTER TABLE operations: moving, splitting, or merging table partitions or subpartitions; moving a table; or converting a nonpartitioned table to a partitioned table. The database preserves only the rows that satisfy the condition specified in the `where_clause`. Refer to the [`where\_clause`](#) in the documentation on SELECT for the full semantics of this clause.

### **Restrictions on Filter Conditions**

The following restrictions apply to the `filter_condition` clause:

- Filter conditions are supported only for heap-organized tables.
- Filter conditions can refer only to columns in the table being altered. Filter conditions cannot contain operations, such as joins or subqueries, that reference other database objects.
- Filter conditions are unsupported for tables with primary or unique keys that are referenced by enabled foreign keys.

### **Restrictions and Notes on Using Filter Conditions with Online Operations**

The following restrictions and notes apply when you specify a filter condition for an online ALTER TABLE operation:

- You cannot specify both the `filter_condition` and ONLINE clauses if supplemental logging is enabled.
- When you specify both the `filter_condition` and ONLINE clauses, DML operations on the table are allowed during the ALTER TABLE operation. The filter condition does not have a direct effect on the concurrent DML operations. However, consider this combination carefully, because the filter operation and the DML operations could unintentionally conflict, as follows:
  - Inserts into a nonpartitioned table will succeed. Inserts into a partitioned table will succeed if they do not violate the partitioning key criteria.

- Delete operations will apply only to rows that are preserved by the filter condition throughout the `ALTER TABLE` operation.
- Update operations will apply only to rows that are preserved by the filter condition throughout the `ALTER TABLE` operation. These update operations will succeed, regardless of whether the update operation would have disqualified the rows for preservation by the filter condition.
- Rows that do not qualify for preservation by the filter condition at the onset of the `ALTER TABLE` operation will not be preserved, regardless of whether an update operation would qualify the rows for preservation.

#### **`allow_disallow_clustering`**

This clause is valid for tables that use attribute clustering. It lets you allow or disallow attribute clustering for data movement that occurs during the move table operation specified by the `move_table_clause`, and the table partition and subpartition maintenance operations specified by the `coalesce_table_[sub]partition`, `merge_table_[sub]partitions`, `move_table_[sub]partition`, and `split_table_[sub]partition` clauses.

- Specify `ALLOW CLUSTERING` to allow attribute clustering for data movement. This clause overrides a `NO ON DATA MOVEMENT` setting in the DDL that created or altered the table.
- Specify `DISALLOW CLUSTERING` to disallow attribute clustering for data movement. This clause overrides a `YES ON DATA MOVEMENT` setting in the DDL that created or altered the table.

The `allow_disallow_clustering` clause has no effect if you specify it for a table that does not use attribute clustering.

#### See Also:

[clustering\\_when](#) clause of `CREATE TABLE` for more information on the `NO ON DATA MOVEMENT` and `YES ON DATA MOVEMENT` clauses

#### **{ DEFERRED | IMMEDIATE } INVALIDATION**

This clause lets you control when the database invalidates dependent cursors while performing table partition maintenance operations.

- If you specify `DEFERRED INVALIDATION`, then the database avoids or defers invalidating dependent cursors, when possible.
- If you specify `IMMEDIATE INVALIDATION`, then the database immediately invalidates dependent cursors, as it did in Oracle Database 12c Release 1 (12.1) and prior releases. This is the default.

If you omit this clause, then the value of the `CURSOR_INVALIDATION` initialization parameter determines when cursors are invalidated.

You can specify this clause only when performing table partition maintenance operations; it is not supported for any other `ALTER TABLE` operations.

 **See Also:**

- *Oracle Database SQL Tuning Guide* for more information on cursor invalidation
- *Oracle Database Reference* for more information in the `CURSOR_INVALIDATION` initialization parameter

**`move_table_clause`**

The `move_table_clause` lets you relocate data of a nonpartitioned or partitioned table into new segments. Alternatively you can move a partition or subpartition of a partitioned table into a new segment, optionally in a different tablespace, and optionally modify any of its storage attributes.

You can also move any LOB data segments associated with the table or partition using the `LOB_storage_clause` and `varray_col_properties` clause. LOB items not specified in this clause are not moved.

**Moving Partitions and Subpartitions of Heap-Organized Tables**

You can move all the partitions and subpartitions of a partitioned heap-organized table with a single `ALTER TABLE MOVE` statement.

Existing partition and subpartition properties that are not modified on table level will be preserved. For example, if you specify `COMPRESS` for the `ALTER TABLE MOVE` command, then all partitions will be compressed, whereas the tablespace location for each partition will be preserved. Conversely, if you specify a target tablespace for the `ALTER TABLE MOVE`, then all partitions will reside in the specified tablespace after the move, but the individual compression attribute for each partition will be preserved.

**Restrictions on Moving All Partitions and Subpartitions of a Partitioned Table with One Command**

- You cannot use this functionality if a domain index is defined on the table.
- You cannot use this functionality if the table has columns of type `VARRAY`.
- You cannot change the attribute clustering properties.
- You can only control table-level segment attributes clauses, such as tablespace or compression. Any segment attribute that is managed as default on the table-level is not supported.
- You cannot use this functionality for an index-organized table .

**ONLINE Clause**

Specify `ONLINE` if you want DML operations on the table to be allowed while the table is being moved.

**Restrictions on Moving Tables Online**

Moving tables online is subject to the following restrictions:

- You cannot combine this clause with any other clause in the same statement.
- You cannot specify this clause for a partitioned index-organized table.

- You cannot specify this clause if a domain index is defined on the table, like spatial, XML, or Text indexes.
- Parallel DML and direct path `INSERT` operations require an exclusive lock on the table. Therefore, these operations are not supported concurrently with an ongoing online table `MOVE`, due to conflicting locks.
- You cannot specify this clause for index-organized tables that contain any LOB, `VARRAY`, Oracle-supplied type, or user-defined object type columns.

#### ***index\_org\_table\_clause***

For an index-organized table, the `index_org_table_clause` of the `move_table_clause` lets you additionally specify overflow segment attributes. The `move_table_clause` rebuilds the primary key index of the index-organized table. The overflow data segment is not rebuilt unless the `OVERFLOW` keyword is explicitly stated, with two exceptions:

- If you alter the values of `PCTTHRESHOLD` or the `INCLUDING` column as part of this `ALTER TABLE` statement, then the overflow data segment is rebuilt.
- If you explicitly move any of out-of-line columns (LOBs, varrays, nested table columns) in the index-organized table, then the overflow data segment is also rebuilt.

The index and data segments of LOB columns are not rebuilt unless you specify the LOB columns explicitly as part of this `ALTER TABLE` statement.

#### ***mapping\_table\_clause***

Specify `MAPPING TABLE` if you want Oracle Database to create a mapping table if one does not already exist. If it does exist, then the database moves the mapping table along with the index-organized table, and marks any bitmapped indexes `UNUSABLE`. The new mapping table is created in the same tablespace as the parent table.

Specify `NOMAPPING` to instruct the database to drop an existing mapping table.

Refer to [mapping\\_table\\_clauses](#) (in `CREATE TABLE`) for more information on this clause.

#### **Restriction on Mapping Tables**

You cannot specify `NOMAPPING` if any bitmapped indexes have been defined on `table`.

#### ***prefix\_compression***

Use the `prefix_compression` clause to enable or disable prefix compression in an index-organized table.

- `COMPRESS` enables prefix compression, which eliminates repeated occurrence 1 of primary key column values in index-organized tables. Use `integer` to specify the prefix length (number of prefix columns to compress).

The valid range of prefix length values is from 1 to the number of primary key columns minus 1. The default prefix length is the number of primary key columns minus 1.

- `NOCOMPRESS` disables prefix compression in index-organized tables. This is the default.

#### ***TABLESPACE tablespace***

Specify the tablespace into which the rebuilt index-organized table is to be stored.

***LOB\_storage\_clause***

Use this clause to move a LOB segment to a different tablespace. You cannot use this clause to move a LOB segment if the table contains a `LONG` column. Instead, you must either convert the `LONG` column to a LOB, or you must export the table, re-create the table specifying the desired tablespace storage for the LOB column, and re-import the table data.

**UPDATE INDEXES**

This clause is valid only when performing online or offline moves of heap-organized tables. It allows you to update all global indexes on the table.

You can optionally change the tablespace for an index or index partition, as follows:

- Specify the `segment_attributes_clause` to change the tablespace of a nonpartitioned global index. Within this clause, you can specify only the `TABLESPACE` clause.
- Specify the `update_index_partition` clause to change the tablespace for a partition of a partitioned global index. Within this clause, you can specify only the `TABLESPACE` clause of the `segment_attributes_clause`.

**Restrictions on Moving Tables**

Moving tables is subject to the following restrictions:

- If you specify `MOVE`, then it must be the first clause in the `ALTER TABLE` statement, and the only clauses outside this clause that are allowed are the `physical_attributes_clause`, the `parallel_clause`, and the `LOB_storage_clause`.
- You cannot move a table containing a `LONG` or `LONG RAW` column.
- You cannot `MOVE` an entire partitioned table (either heap- or index-organized). You must move individual partitions or subpartitions.

**Note:**

For any LOB columns you specify in a `move_table_clause`:

- Oracle Database drops the old LOB data segment and corresponding index segment and creates new segments, even if you do not specify a new tablespace.
- If the LOB index in `table` resided in a different tablespace from the LOB data, then Oracle Database collocates the LOB index in the same tablespace with the LOB data after the move.

**See Also:**

[move\\_table\\_partition](#) and [move\\_table\\_subpartition](#)

***modify\_to\_partitioned***

Use this clause to partition a nonpartitioned or partitioned table, including indexes, online or offline.

You can change a nonpartitioned or partitioned table into any type of partitioned or composite partitioned table with the following characteristics:

- All data in the original table is preserved.
- The data in the newly created partitions or subpartitions of the modified table is stored in the same tablespace as the original table, unless you specify otherwise in the *table\_partitioning\_clauses*.
- Local index partitions or subpartitions and lob partitions or subpartitions of the modified table will be co-located with the table partitions or subpartitions unless you specify otherwise in the *table\_partitioning\_clauses*.
- All triggers, constraints, and VPD policies defined on the original table are preserved.
- If table compression is defined on the original nonpartitioned table, then the partitioned table will use the same type of table compression.
- In case of modifying a partitioned table, the compression setting of the newly created partitions or subpartitions is derived from the default compression setting of the partitioned table prior to the modification unless all partitions or subpartitions shared the same compression method.

Each range, list, or hash partitioning or subpartitioning key column with a character data type, specified in the *modify\_to\_partitioned* clause must have one of the following declared collations: BINARY, USING\_NLS\_COMP, USING\_NLS\_SORT, or USING\_NLS\_SORT\_CS.

#### ***table\_partitioning\_clauses***

Use this clause to specify the partitioning attributes for the table.

Each range, list, or hash partitioning or subpartitioning key column with a character data type, specified in the *modify\_to\_partitioned* clause must have one of the following declared collations: BINARY, USING\_NLS\_COMP, USING\_NLS\_SORT, or USING\_NLS\_SORT\_CS.

This clause has the same semantics here as it has for the CREATE TABLE statement. Refer to the CREATE TABLE *table\_partitioning\_clauses* for the full semantics of this clause.

#### **NONPARTITIONED**

Specify NONPARTITIONED to convert a partitioned table back to a nonpartitioned state.

#### **ONLINE**

Specify ONLINE to indicate that DML operations on the table will be allowed while changing to a partitioned table.

#### **UPDATE INDEXES**

Use this clause to specify how existing indexes on the table are converted into global partitioned indexes or local partitioned indexes.

- For *index*, specify the name of an existing index on the table.
- Specify the *local\_partitioned\_index* clause to convert *index* into a local partitioned index. This clause has the same semantics here as it has for the

CREATE INDEX statement. Refer to the clause *local\_partitioned\_index* in the documentation on CREATE INDEX for the full semantics of this clause.

- Specify the *global\_partitioned\_index* clause to convert *index* into a global partitioned index. This clause has the same semantics here as it has for the CREATE INDEX statement. Refer to the clause *global\_partitioned\_index* in the documentation on CREATE INDEX for the full semantics of this clause.
- Specify the GLOBAL keyword to allow prefixed partitioned and nonpartitioned global indexes to retain their global shape. This clause prevents such indexes from being converted to local partitioned indexes; it has no effect on nonprefixed global indexes.

If you specify only the UPDATE INDEXES keywords, or omit the UPDATE INDEXES clause altogether, then existing indexes are converted as follows:

- Nonprefixed indexes retain their original shape: normal indexes are converted to nonpartitioned global indexes, nonpartitioned global indexes remain the same, and partitioned global indexes remain the same and retain their partitioning shape.
- Prefixed indexes are converted to local partitioned indexes. Prefixed indexes include partitioning keys in the index definition, but the index definition is not limited to including only the partitioning keys.
- Bitmap indexes are converted to local partitioned indexes, regardless of whether they are prefixed or not.

### Default Index Rules for Conversion from Partitioned to Partitioned Table

The rule set for default index conversion for partitioned to partitioned table is identical to the one for nonpartitioned to partitioned table, with additional handling of existing local indexes on the partitioned table.

- If the index is already local, then the index stays as a local index if the index column is prefixed on both sides of the partitioning dimensions.
- If the partitioning columns are a subset of the key columns, (that is, they are prefixed), then the global index is converted to local. If the global index is not prefixed, then the shape of the global index is retained.

### Restrictions on Changing a Nonpartitioned Table to a Partitioned Table

The following restrictions apply to the *modify\_to\_partitioned* clause:

- You cannot specify this clause for an index-organized table.
- You cannot specify this clause if a domain index is defined on the table.
- You cannot specify ONLINE when changing a nonpartitioned table to a reference-partitioned child table. This operation is supported only in offline mode.

#### See Also:

*Oracle Database VLDB and Partitioning Guide* for more information on converting a nonpartitioned table into a partitioned table

### *modify\_opaque\_type*

Use the *modify\_opaque\_type* clause to instruct the database to store the specified abstract data type or XMLType in an ANYDATA column using unpacked storage.

You can specify any abstract data type with this clause. However, it is primarily useful because it allows you to specify the following data types, which cannot be stored in an ANYDATA column using conventional storage:

- XMLType
- Abstract data types that contain one or more attributes of type XMLType, CLOB, BLOB, or NCLOB.

When you use **unpacked storage**, data types are stored in system-generated hidden columns that are associated with the ANYDATA column. You can insert and query these data types as you would data types that are stored in an ANYDATA column using conventional storage.

#### ***anydata\_column***

Specify the name of a column of type ANYDATA. If *type\_name* is an abstract data type that does not contain an attribute of type XMLType, CLOB, BLOB, or NCLOB, then *anydata\_column* must be empty.

#### ***type\_name***

Specify the name of one or more abstract data types or XMLType. The abstract data type can contain an attribute of type XMLType, CLOB, BLOB, or NCLOB. The type can be EDITIONABLE. When you subsequently insert these data types into *anydata\_column*, they will use unpacked storage. If you previously specified this clause for the same *anydata\_column*, then unpacked storage will continue to be used for the previously specified data types as well as the newly specified data types.

#### **See Also:**

*Oracle Database PL/SQL Packages and Types Reference* for information on the ANYDATA type and "["Unpacked Storage in ANYDATA Columns: Example"](#)"

#### ***immutable\_table\_clauses***

You can use the NO DROP or NO DELETE clauses to modify the definition of an immutable table.

Use the NO DROP clause to modify the retention period for an immutable table or the retention period for rows within the immutable table. You cannot reduce the retention period.

#### **Example : Modifying the Retention Period for an Immutable Table**

The following statement modifies the definition of the immutable table *imm\_tab* and specifies that it cannot be dropped if the newest row is less than 50 days old.

```
ALTER TABLE imm_tab NO DROP UNTIL 50 DAYS IDLE;
```

#### **Example : Modifying the Retention Period for Immutable Table Rows**

The following statement modifies the definition of the immutable table *imm\_tab* and specifies that rows cannot be deleted until 120 days after they were created.

```
ALTER TABLE imm_tab NO DELETE UNTIL 120 DAYS AFTER
INSERT;
```

### ***blockchain\_table\_clauses***

You can modify a table created using the keyword `BLOCKCHAIN` in the `ALTER TABLE` statement, and one or more of the `blockchain_table_clauses`.

See `blockchain_table_clauses` of [CREATE TABLE](#) for the full semantics of the clause.

You can add, drop, and rename a column in a V2 blockchain table.

Use the `blockchain_system_chains_clause` to configure the number of system chains in a blockchain table. The range of permissible values is 1 to 1024. For `ALTER TABLE`, you can increase or decrease the number of system chains per instance, but you cannot configure a number of system chains per instance that is less than the maximum number of a system chain already in the blockchain table.

You cannot use the `blockchain_hash_and_data_format_clause` of the `blockchain_table_clauses` in the `ALTER TABLE` statement.

### **Restrictions on All Versions of Blockchain Tables V1 and V2**

You can use all the clauses of `ALTER TABLE` on a blockchain table except the following clauses:

- `DROP (SUB) PARTITION`
- `TRUNCATE (SUB) PARTITION`
- `EXCHANGE (SUB) PARTITION`
- `MODIFY TYPE`
- `RENAME TABLE`

### **Additional Restrictions on V1 Blockchain Tables**

The following `ADD`, `DROP`, and `RENAME COLUMN` restrictions apply to V1 blockchain tables but not V2 blockchain tables:

- `RENAME COLUMN`
- `ADD COLUMN`
- `DROP COLUMN`

### ***duplicated\_table\_refresh***

Use this clause to specify fine-grained refresh rate control for a duplicated table when it is created with `CREATE TABLE`. You can also specify the refresh rate later with `ALTER TABLE`.

### ***enable\_disable\_clause***

The `enable_disable_clause` lets you specify whether and how Oracle Database should apply an integrity constraint. The `DROP` and `KEEP` clauses are valid only when you are disabling a unique or primary key constraint.

 **See Also:**

The [enable\\_disable\\_clause](#) (in CREATE TABLE) for a complete description of this clause, including notes and restrictions that relate to this statement

**TABLE LOCK**

Oracle Database permits DDL operations on a table only if the table can be locked during the operation. Such table locks are not required during DML operations.

 **Note:**

Table locks are not acquired on temporary tables.

- Specify `ENABLE TABLE LOCK` to enable table locks, thereby allowing DDL operations on the table. All currently executing transactions must commit or roll back before Oracle Database enables the table lock.

 **Note:**

Oracle Database waits until active DML transactions in the database have completed before locking the table. Sometimes the resulting delay is considerable.

- Specify `DISABLE TABLE LOCK` to disable table locks, thereby preventing DDL operations on the table.

 **Note:**

Parallel DML operations are not performed when the table lock of the target table is disabled.

**ALL TRIGGERS**

Use the `ALL TRIGGERS` clause to enable or disable all triggers associated with the table.

- Specify `ENABLE ALL TRIGGERS` to enable all triggers associated with the table. Oracle Database fires the triggers whenever their triggering condition is satisfied.

To enable a single trigger, use the `enable_clause` of `ALTER TRIGGER`.

 **See Also:**

[CREATE TRIGGER](#) , [ALTER TRIGGER](#) , and "Enabling Triggers: Example"

- Specify `DISABLE ALL TRIGGERS` to disable all triggers associated with the table. Oracle Database does not fire a disabled trigger even if the triggering condition is satisfied.

## **CONTAINER\_MAP**

Use the `CONTAINER_MAP` clause to enable or disable the table to be queried using a container map.

- Specify `ENABLE CONTAINER_MAP` to enable the table to be queried using a container map.
- Specify `DISABLE CONTAINER_MAP` to disable the table from being queried using a container map.

## **CONTAINERS\_DEFAULT**

Use the `CONTAINERS_DEFAULT` clause to enable or disable the table for the `CONTAINERS` clause.

- Specify `ENABLE CONTAINERS_DEFAULT` to enable the table for the `CONTAINERS` clause.
- Specify `DISABLE CONTAINERS_DEFAULT` to disable the table for the `CONTAINERS` clause.

## **Examples**

### **Adding Constraints to Tables: Example**

The following statements create a new table to manipulate data and display the information in the newly created table:

```
CREATE TABLE JOBS_Temp AS SELECT * FROM HR.JOBS;

SELECT * FROM JOBS_Temp WHERE MIN_SALARY < 3000;

JOB_ID      JOB_TITLE          MIN_SALARY MAX_SALARY
-----      -----          -----
PU_CLERK    Purchasing Clerk      2500     5500
ST_CLERK    Stock Clerk          2008     5000
SH_CLERK    Shipping Clerk       2500     5500
```

The following statement updates the column values to a higher value:

```
UPDATE JOBS_Temp SET MIN_SALARY = 2300 WHERE MIN_SALARY < 2010;
```

The following statement adds a constraint:

```
ALTER TABLE JOBS_Temp ADD CONSTRAINT chk_sal_min CHECK (MIN_SALARY >=2010);
```

The following statement displays the table information:

```
SELECT * FROM JOBS_Temp WHERE MIN_SALARY < 3000;
```

```
JOB_ID      JOB_TITLE          MIN_SALARY MAX_SALARY
-----      -----          -----
PU_CLERK    Purchasing Clerk      2500     5500
ST_CLERK    Stock Clerk          2300     5000
SH_CLERK    Shipping Clerk       2500     5500
```

The following statement displays the constraint:

```
SELECT CONSTRAINT_NAME FROM USER_CONSTRAINTS WHERE TABLE_NAME='JOBS_TEMP';
```

```
CONSTRAINT_NAME
-----
```

```
SYS_C008830
CHK_SAL_MIN
```

### **Adding and Modifying Precheck State Constraint: Example**

The following statement create a product table with constraint state PRECHECK set on some columns:

```
CREATE TABLE product(
    id NUMBER NOT NULL PRIMARY KEY,
    name VARCHAR2(50),
    price NUMBER CHECK (mod(price,4) = 0 and 10 <> price) PRECHECK,
    color NUMBER CHECK (color >= 10 and color <=50 and mod(color,2) = 0)
        PRECHECK,
    description VARCHAR2(50) CHECK (length(description) <= 40) PRECHECK,
    constant NUMBER CHECK (constant=10) PRECHECK,
    CONSTRAINT TC1 CHECK (color > 0 AND price > 10) PRECHECK,
    CONSTRAINT TC2 CHECK (CATEGORY IN ('home', 'apparel') AND price > 10)
) ;
```

Add precheck to a new constraint

```
ALTER TABLE product MODIFY (name VARCHAR2(50) CHECK
    (regexp_like(name, '^Product')) PRECHECK);
```

Modify an existing constraint TC2:

```
ALTER TABLE product MODIFY CONSTRAINT TC2 PRECHECK;
```

Remove an existing precheck constraint on TC1:

```
ALTER TABLE product MODIFY CONSTRAINT TC1 NOPRECHECK;
```

### **Collection Retrieval: Example**

The following statement modifies nested table column ad\_textdocs\_ntab in the sample table sh.print\_media so that when queried it returns actual values instead of locators:

```
ALTER TABLE print_media MODIFY NESTED TABLE ad_textdocs_ntab
    RETURN AS VALUE;
```

### **Specifying Parallel Processing: Example**

The following statement specifies parallel processing for queries to the sample table oe.customers:

```
ALTER TABLE customers
    PARALLEL;
```

### **Changing the State of a Constraint: Examples**

The following statement places in ENABLE VALIDATE state an integrity constraint named emp\_manager\_fk in the employees table:

```
ALTER TABLE employees
    ENABLE VALIDATE CONSTRAINT emp_manager_fk
    EXCEPTIONS INTO exceptions;
```

Each row of the employees table must satisfy the constraint for Oracle Database to enable the constraint. If any row violates the constraint, then the constraint remains

disabled. The database lists any exceptions in the table exceptions. You can also identify the exceptions in the employees table with the following statement:

```
SELECT e.*  
  FROM employees e, exceptions ex  
 WHERE e.rowid = ex.row_id  
   AND ex.table_name = 'EMPLOYEES'  
   AND ex.constraint = 'EMP_MANAGER_FK';
```

The following statement tries to place in ENABLE NOVALIDATE state two constraints on the employees table:

```
ALTER TABLE employees  
  ENABLE NOVALIDATE PRIMARY KEY  
  ENABLE NOVALIDATE CONSTRAINT emp_last_name_nn;
```

This statement has two ENABLE clauses:

- The first places a primary key constraint on the table in ENABLE NOVALIDATE state.
- The second places the constraint named emp\_last\_name\_nn in ENABLE NOVALIDATE state.

In this case, Oracle Database enables the constraints only if both are satisfied by each row in the table. If any row violates either constraint, then the database returns an error and both constraints remain disabled.

Consider the foreign key constraint on the location\_id column of the departments table, which references the primary key of the locations table. The following statement disables the primary key of the locations table:

```
ALTER TABLE locations  
  MODIFY PRIMARY KEY DISABLE CASCADE;
```

The unique key in the locations table is referenced by the foreign key in the departments table, so you must specify CASCADE to disable the primary key. This clause disables the foreign key as well.

### Creating an Exceptions Table for Index-Organized Tables: Example

The following example creates the except\_table table to hold rows from the index-organized table hr.countries that violate the primary key constraint:

```
EXECUTE DBMS_IOT.BUILD_EXCEPTIONS_TABLE ('hr', 'countries', 'except_table');  
  
ALTER TABLE countries  
  ENABLE PRIMARY KEY  
  EXCEPTIONS INTO except_table;
```

To specify an exception table, you must have the privileges necessary to insert rows into the table. To examine the identified exceptions, you must have the privileges necessary to query the exceptions table.

#### See Also:

[INSERT](#) and [SELECT](#) for information on the privileges necessary to insert rows into tables

### Disabling a CHECK Constraint: Example

The following statement defines and disables a CHECK constraint on the employees table:

```
ALTER TABLE employees ADD CONSTRAINT check_comp
    CHECK (salary + (commission_pct*salary) <= 5000)
    DISABLE;
```

The constraint `check_comp` ensures that no employee's total compensation exceeds \$5000. The constraint is disabled, so you can increase an employee's compensation above this limit.

### Enabling Triggers: Example

The following statement enables all triggers associated with the employees table:

```
ALTER TABLE employees
    ENABLE ALL TRIGGERS;
```

### Deallocating Unused Space: Example

The following statement frees all unused space for reuse in table `employees`, where the high water mark is above MINEXTENTS:

```
ALTER TABLE employees
    DEALLOCATE UNUSED;
```

### Modifying the Collation of a Column for Fine-Grained Case-Insensitivity: Example

This example shows how to modify a column to be case-insensitive. First, create and populate table `students` as follows:

```
CREATE TABLE students (last_name VARCHAR2(20), id NUMBER);

INSERT INTO students VALUES('Dodd', 364);
INSERT INTO students VALUES('de Niro', 132);
INSERT INTO students VALUES('Vogel', 837);
INSERT INTO students VALUES('van der Kamp', 549);
INSERT INTO students VALUES('van Der Meer', 624);
```

The following statement returns column `last_name` in alphabetical order. Notice that the results are case-sensitive; lowercase letters are ordered after uppercase letters.

```
SELECT last_name, id
    FROM students
    ORDER BY last_name;
```

LAST_NAME	ID
Dodd	364
Vogel	837
de Niro	132
van Der Meer	624
van der Kamp	549

The following statement changes the data-bound collation of column `last_name` to case-insensitive collation `BINARY_CI`:

```
ALTER TABLE students
    MODIFY (last_name COLLATE BINARY_CI);
```

The following statement again returns column `last_name` in alphabetical order. Notice that the results are now case-insensitive:

```
SELECT last_name, id
    FROM students
    ORDER BY last_name;
```

LAST_NAME	ID
de Niro	132
Dodd	364
van der Kamp	549
van Der Meer	624
Vogel	837

### **Renaming a Column: Example**

The following example renames the `credit_limit` column of the sample table `oe.customers` to `credit_amount`:

```
ALTER TABLE customers
    RENAME COLUMN credit_limit TO credit_amount;
```

### **Dropping a Column: Example**

This statement illustrates the `drop_column_clause` with `CASCADE CONSTRAINTS`. Assume table `t1` is created as follows:

```
CREATE TABLE t1 (
    pk NUMBER PRIMARY KEY,
    fk NUMBER,
    c1 NUMBER,
    c2 NUMBER,
    CONSTRAINT ri FOREIGN KEY (fk) REFERENCES t1,
    CONSTRAINT ck1 CHECK (pk > 0 and c1 > 0),
    CONSTRAINT ck2 CHECK (c2 > 0)
);
```

An error will be returned for the following statements:

```
ALTER TABLE t1 DROP (pk); -- pk is a parent key
ALTER TABLE t1 DROP (c1); -- c1 is referenced by multicolumn
                          -- constraint ck1
```

Submitting the following statement drops column `pk`, the primary key constraint, the foreign key constraint, `ri`, and the check constraint, `ck1`:

```
ALTER TABLE t1 DROP (pk) CASCADE CONSTRAINTS;
```

If all columns referenced by the constraints defined on the dropped columns are also dropped, then `CASCADE CONSTRAINTS` is not required. For example, assuming that no other referential constraints from other tables refer to column `pk`, then it is valid to submit the following statement without the `CASCADE CONSTRAINTS` clause:

```
ALTER TABLE t1 DROP (pk, fk, c1);
```

### **Dropping Unused Columns: Example**

The following statements create a new table to manipulate data and display the information in the newly created table:

```
CREATE TABLE JOBS_Temp AS SELECT * FROM HR.JOBS;

SELECT * FROM JOBS_Temp WHERE MAX_SALARY > 20000;

JOB_ID      JOB_TITLE          MIN_SALARY MAX_SALARY
-----      -----          -----
AD_PRES     President           20080      40000
AD_VP       Administration Vice President   15000      30000
SA_MAN     Sales Manager        10000      20080
```

The following statement adds two new columns:

```
ALTER TABLE JOBS_Temp ADD (DUMMY1 NUMBER(2), DUMMY2 NUMBER(2));
```

The following statements inserts values into the newly added columns:

```
INSERT INTO JOBS_Temp(JOB_ID, JOB_TITLE, DUMMY1, DUMMY2) VALUES
('D','DUMMY',10,20);
```

```
INSERT INTO JOBS_Temp(JOB_ID, JOB_TITLE, DUMMY1, DUMMY2) VALUES
('D','DUMMY',10,20)
```

The following statement sets the newly added columns to unused:

```
ALTER TABLE JOBS_TEMP SET UNUSED (DUMMY1, DUMMY2);
```

The following statement displays the count of unused columns:

```
SELECT * FROM USER_UNUSED_COL_TABS WHERE TABLE_NAME='JOBS_TEMP';

TABLE_NAM      COUNT
-----      -----
JOBS_TEMP      2
```

The following statement drops the unused columns:

```
ALTER TABLE JOBS_TEMP DROP UNUSED COLUMNS;
```

The following statement displays the table information:

```
SELECT * FROM JOBS_TEMP;
```

```
JOB_ID      JOB_TITLE          MIN_SALARY MAX_SALARY
-----      -----          -----
AD_PRES     President           20080      40000
AD_VP       Administration Vice President   15000      30000
AD_ASST     Administration Assistant      3000      6000
FI_MGR      Finance Manager        8200      16000
FI_ACCOUNT  Accountant          4200      9000
AC_MGR      Accounting Manager      8200      16000
AC_ACCOUNT  Public Accountant      4200      9000
SA_MAN     Sales Manager          10000      20080
SA_REP      Sales Representative      6000      12008
PU_MAN     Purchasing Manager      8000      15000
PU_CLERK    Purchasing Clerk        2500      5500
ST_MAN     Stock Manager          5500      8500
ST_CLERK    Stock Clerk            2008      5000
SH_CLERK    Shipping Clerk          2500      5500
IT_PROG     Programmer            4000      10000
```

MK_MAN	Marketing Manager	9000	15000
MK REP	Marketing Representative	4000	9000
HR REP	Human Resources Representative	4000	9000
PR REP	Public Relations Representative	4500	10500
D	DUMMY		
D	DUMMY		

### Modifying Index-Organized Tables: Examples

This statement modifies the INITRANS parameter for the index segment of index-organized table `countries_demo`, which is based on `hr.countries`:

```
ALTER TABLE countries_demo INITRANS 4;
```

The following statement adds an overflow data segment to index-organized table `countries`:

```
ALTER TABLE countries_demo ADD OVERFLOW;
```

This statement modifies the INITRANS parameter for the overflow data segment of index-organized table `countries`:

```
ALTER TABLE countries_demo OVERFLOW INITRANS 4;
```

### Splitting Table Partitions: Examples

The following statement splits the old partition `sales_q4_2000` in the sample table `sh.sales`, creating two new partitions, naming one `sales_q4_2000b` and reusing the name of the old partition for the other:

```
ALTER TABLE sales SPLIT PARTITION SALES_Q4_2000
  AT (TO_DATE('15-NOV-2000','DD-MON-YYYY'))
  INTO (PARTITION SALES_Q4_2000, PARTITION SALES_Q4_2000b);
```

The following statement splits the old partition `sales_q1_2002` into three new partitions `sales_jan_2002`, `sales_feb_2002`, and `sales_mar_2002`:

```
ALTER TABLE sales SPLIT PARTITION SALES_Q1_2002 INTO (
  PARTITION SALES_JAN_2002 VALUES LESS THAN (TO_DATE('01-FEB-2002','DD-MON-YYYY')),
  PARTITION SALES_FEB_2002 VALUES LESS THAN (TO_DATE('01-MAR-2002','DD-MON-YYYY')),
  PARTITION SALES_MAR_2002);
```

The following statements create a partitioned version of the `pm.print_media` table. The `LONG` column in the `print_media` table has been converted to LOB. The table is stored in tablespaces created in "Creating Oracle Managed Files: Examples". The object types underlying the `ad_textdocs_ntab` and `ad_header` columns are created in the script that creates the `pm` sample schema:

```
CREATE TABLE print_media_part (
  product_id NUMBER(6),
  ad_id NUMBER(6),
  ad_composite BLOB,
  ad_sourcetext CLOB,
  ad_finaltext CLOB,
  ad_ftextn NCLOB,
  ad_textdocs_ntab TEXTDOC_TAB,
  ad_photo BLOB,
  ad_graphic BFILE,
  ad_header ADHEADER_TYP)
  NESTED TABLE ad_textdocs_ntab STORE AS textdoc_nt
  PARTITION BY RANGE (product_id)
```

```
(PARTITION p1 VALUES LESS THAN (100),
PARTITION p2 VALUES LESS THAN (200));
```

The following statement splits partition p2 of that table into partitions p2a and p2b:

```
ALTER TABLE print_media_part
SPLIT PARTITION p2 AT (150) INTO
(PARTITION p2a TABLESPACE omf_ts1
LOB (ad_photo, ad_composite) STORE AS (TABLESPACE omf_ts2),
PARTITION p2b
LOB (ad_photo, ad_composite) STORE AS (TABLESPACE omf_ts2))
NESTED TABLE ad_textdocs_ntab INTO (PARTITION nt_p2a, PARTITION nt_p2b);
```

In both partitions p2a and p2b, Oracle Database creates the LOB segments for columns ad\_photo and ad\_composite in tablespace omf\_ts2. The LOB segments for the remaining columns in partition p2a are stored in tablespace omf\_ts1. The LOB segments for the remaining columns in partition p2b remain in the tablespaces in which they resided prior to this ALTER statement. However, the database creates new segments for all the LOB data and LOB index segments, even if they are not moved to a new tablespace.

The database also creates new segments for nested table column ad\_textdocs\_ntab. The storage tables is those new segments are nt\_p2a and nt\_p2b.

### Merging Two Table Partitions: Example

The following statement merges back into one partition the partitions created in "[Splitting Table Partitions: Examples](#)":

```
ALTER TABLE sales
MERGE PARTITIONS sales_q4_2000, sales_q4_2000b
INTO PARTITION sales_q4_2000;
```

The next statement reverses the example in "[Splitting Table Partitions: Examples](#)":

```
ALTER TABLE print_media_part
MERGE PARTITIONS p2a, p2b INTO PARTITION p2ab TABLESPACE example
NESTED TABLE ad_textdocs_ntab STORE AS nt_p2ab;
```

### Merging Four Adjacent Range Partitions: Example

The following statement merges four adjacent range partitions, sales\_q1\_2000, sales\_q2\_2000, sales\_q3\_2000, and sales\_q4\_2000 into one partition sales\_all\_2000:

```
ALTER TABLE sales
MERGE PARTITIONS sales_q1_2000 TO sales_q4_2000
INTO PARTITION sales_all_2000;
```

### Adding a Table Partition with a LOB and Nested Table Storage: Examples

The following statement adds a partition p3 to the print\_media\_part table (see preceding example) and specifies storage characteristics for the BLOB, CLOB, and nested table columns of that table:

```
ALTER TABLE print_media_part ADD PARTITION p3 VALUES LESS THAN (400)
LOB(ad_photo, ad_composite) STORE AS (TABLESPACE omf_ts1)
LOB(ad_sourcetext, ad_finaltext) STORE AS (TABLESPACE omf_ts2)
NESTED TABLE ad_textdocs_ntab STORE AS nt_p3;
```

The LOB data and LOB index segments for columns `ad_photo` and `ad_composite` in partition `p3` will reside in tablespace `omf_ts1`. The remaining attributes for these LOB columns will be inherited first from the table-level defaults, and then from the tablespace defaults.

The LOB data segments for columns `ad_source_text` and `ad_finaltext` will reside in the `omf_ts2` tablespace, and will inherit all other attributes first from the table-level defaults, and then from the tablespace defaults.

The partition for the storage table for nested table storage column `ad_textdocs_ntab` corresponding to partition `p3` of the base table is named `nt_p3` and inherits all other attributes first from the table-level defaults, and then from the tablespace defaults.

### Adding Multiple Partitions to a Table: Example

The following statement adds three partitions to the table `print_media_part` created in "[Splitting Table Partitions: Examples](#)":

```
ALTER TABLE print_media_part ADD
  PARTITION p3 values less than (300),
  PARTITION p4 values less than (400),
  PARTITION p5 values less than (500);
```

### Working with Default List Partitions: Example

The following statements use the list partitioned table created in "[List Partitioning Example](#)". The first statement splits the existing default partition into a new `south` partition and a default partition:

```
ALTER TABLE list_customers SPLIT PARTITION rest
  VALUES ('MEXICO', 'COLOMBIA')
  INTO (PARTITION south, PARTITION rest);
```

The next statement merges the resulting default partition with the `asia` partition:

```
ALTER TABLE list_customers
  MERGE PARTITIONS asia, rest INTO PARTITION rest;
```

The next statement re-creates the `asia` partition by splitting the default partition:

```
ALTER TABLE list_customers SPLIT PARTITION rest
  VALUES ('CHINA', 'THAILAND')
  INTO (PARTITION asia, PARTITION rest);
```

### Dropping a Table Partition: Example

The following statement drops partition `p3` created in "[Adding a Table Partition with a LOB and Nested Table Storage: Examples](#)":

```
ALTER TABLE print_media_part DROP PARTITION p3;
```

### Exchanging Table Partitions: Example

This example creates the table `exchange_table` with the same structure as the partitions of the `list_customers` table created in "[List Partitioning Example](#)". It then replaces partition `rest` of table `list_customers` with table `exchange_table` without exchanging local index partitions with corresponding indexes on `exchange_table` and without verifying that data in `exchange_table` falls within the bounds of partition `rest`:

```
CREATE TABLE exchange_table (
  customer_id      NUMBER(6),
```

```
cust_first_name VARCHAR2(20),
cust_last_name  VARCHAR2(20),
cust_address    CUST_ADDRESS_TYP,
nls_territory   VARCHAR2(30),
cust_email      VARCHAR2(40));

ALTER TABLE list_customers
EXCHANGE PARTITION rest WITH TABLE exchange_table
WITHOUT VALIDATION;
```

### Modifying Table Partitions: Examples

The following statement marks all the local index partitions corresponding to the `asia` partition of the `list_customers` table `UNUSABLE`:

```
ALTER TABLE list_customers MODIFY PARTITION asia
UNUSABLE LOCAL INDEXES;
```

The following statement rebuilds all the local index partitions that were marked `UNUSABLE`:

```
ALTER TABLE list_customers MODIFY PARTITION asia
REBUILD UNUSABLE LOCAL INDEXES;
```

### Moving Table Partitions: Example

The following statement moves partition `p2b` (from "[Splitting Table Partitions: Examples](#)") to tablespace `omf_ts1`:

```
ALTER TABLE print_media_part
MOVE PARTITION p2b TABLESPACE omf_ts1;
```

### Renaming Table Partitions: Examples

The following statement renames a partition of the `sh.sales` table:

```
ALTER TABLE sales RENAME PARTITION sales_q4_2003 TO sales_currentq;
```

### Truncating Table Partitions: Example

The following statement uses the `print_media_demo` table created in "[Partitioned Table with LOB Columns Example](#)". It deletes all the data in the `p1` partition and deallocates the freed space:

```
ALTER TABLE print_media_demo
TRUNCATE PARTITION p1 DROP STORAGE;
```

### Updating Global Indexes: Example

The following statement splits partition `sales_q1_2000` of the sample table `sh.sales` and updates any global indexes defined on it:

```
ALTER TABLE sales SPLIT PARTITION sales_q1_2000
AT (TO_DATE('16-FEB-2000','DD-MON-YYYY'))
INTO (PARTITION q1a_2000, PARTITION q1b_2000)
UPDATE GLOBAL INDEXES;
```

### Updating Partitioned Indexes: Example

The following statement splits partition `costs_Q4_2003` of the sample table `sh.costs` and updates the local index defined on it. It uses the tablespaces created in "[Creating Basic Tablespaces: Examples](#)".

```
CREATE INDEX cost_ix ON costs(channel_id) LOCAL;

ALTER TABLE costs
  SPLIT PARTITION costs_q4_2003 at
    (TO_DATE('01-Nov-2003','dd-mon-yyyy'))
    INTO (PARTITION c_p1, PARTITION c_p2)
  UPDATE INDEXES (cost_ix (PARTITION c_p1 tablespace tbs_02,
                           PARTITION c_p2 tablespace tbs_03));
```

### **Specifying Object Identifiers: Example**

The following statements create an object type, a corresponding object table with a primary-key-based object identifier, and a table having a user-defined `REF` column:

```
CREATE TYPE emp_t AS OBJECT (empno NUMBER, address CHAR(30));

CREATE TABLE emp OF emp_t (
  empno PRIMARY KEY)
  OBJECT IDENTIFIER IS PRIMARY KEY;

CREATE TABLE dept (dno NUMBER, mgr_ref REF emp_t SCOPE is emp);
```

The next statements add a constraint and a user-defined `REF` column, both of which reference table `emp`

```
ALTER TABLE dept ADD CONSTRAINT mgr_cons FOREIGN KEY (mgr_ref)
  REFERENCES emp;
ALTER TABLE dept ADD sr_mgr REF emp_t REFERENCES emp;
```

### **Adding a Table Column: Example**

The following statement adds to the `countries` table a column named `duty_pct` of data type `NUMBER` and a column named `visa_needed` of data type `VARCHAR2` with a size of 3 and a `CHECK` integrity constraint:

```
ALTER TABLE countries
  ADD (duty_pct      NUMBER(2,2)  CHECK (duty_pct < 10.5),
       visa_needed  VARCHAR2(3));
```

### **Adding a Virtual Table Column: Example**

The following statement adds to a copy of the `hr.employees` table a column named `income`, which is a combination of salary plus commission. Both salary and commission are `NUMBER` columns, so the database creates the virtual column as a `NUMBER` column even though the data type is not specified in the statement:

```
CREATE TABLE emp2 AS SELECT * FROM employees;

ALTER TABLE emp2 ADD (income AS (salary + (salary*commission_pct)));
```

### **Modifying Table Columns: Examples**

The following statement increases the size of the `duty_pct` column:

```
ALTER TABLE countries
  MODIFY (duty_pct NUMBER(3,2));
```

Because the `MODIFY` clause contains only one column definition, the parentheses around the definition are optional.

The following statement changes the values of the `PCTFREE` and `PCTUSED` parameters for the `employees` table to 30 and 60, respectively:

```
ALTER TABLE employees
  PCTFREE 30
  PCTUSED 60;
```

### Modifying Storage Attributes for a Table

The following statement creates a table named `JOBS_TEMP` by using the existing `JOBS` table:

```
CREATE TABLE JOBS_TEMP AS SELECT * FROM HR.JOBS;
```

The following statement queries the `USER_TABLES` table for storage parameters:

```
SELECT initial_extent,
       next_extent,
       min_extents,
       max_extents,
       pct_increase,
       blocks,
       sample_size
  FROM user_tables
 WHERE table_name = 'JOBS_TEMP';

INITIAL EXTENT NEXT EXTENT MIN EXTENTS MAX EXTENTS PCT INCREASE
BLOCKS SAMPLE SIZE
----- ----- ----- -----
----- -----
65536      1048576          1
2147483645                      19
```

The following statement alters the `JOBS_TEMP` table with new storage parameters:

```
ALTER TABLE JOBS_TEMP MOVE
  STORAGE ( INITIAL 20K
            NEXT 40K
            MINEXTENTS 2
            MAXEXTENTS 20
            PCTINCREASE 0 )
  TABLESPACE USERS;
```

The following statement queries the `USER_TABLES` table for the new storage parameters:

```
SELECT initial_extent,
       next_extent,
       min_extents,
       max_extents,
       pct_increase,
```

```

blocks,
sample_size
FROM user_tables
WHERE table_name = 'JOBS_TEMP';

INITIAL_EXTENT NEXT_EXTENT MIN_EXTENTS MAX_EXTENTS PCT_INCREASE      BLOCKS
SAMPLE_SIZE
-----
-----  -----  -----  -----  -----
-----  -----  -----  -----  -----
65536      40960          1  2147483645
1           19

```

### **Adding, Altering, Renaming and Dropping Table Columns: Example**

The following statements create a new table to manipulate data and display the information in the newly created table:

```

CREATE TABLE JOBS_Temp AS SELECT * FROM HR.JOBS;

SELECT * FROM JOBS_Temp WHERE MAX_SALARY > 30000;

JOB_ID      JOB_TITLE            MIN_SALARY MAX_SALARY
-----  -----  -----  -----
AD_PRES     President           20080      40000

```

The following statement modifies an existing column definition:

```
ALTER TABLE JOBS_Temp MODIFY (JOB_TITLE VARCHAR2(100));
```

The following statement adds two new columns to the table:

```
ALTER TABLE JOBS_Temp ADD (BONUS NUMBER (7,2), COMM NUMBER (5,2), DUMMY NUMBER(2));
```

The following statement displays the newly added columns:

```

SELECT JOB_ID, BONUS, COMM, DUMMY FROM JOBS_Temp WHERE MAX_SALARY > 20000;

JOB_ID      BONUS      COMM      DUMMY
-----  -----  -----  -----
AD_PRES
AD_VP
SA_MAN

```

The following statements rename an existing column and display the modified column:

```
ALTER TABLE JOBS_Temp RENAME COLUMN COMM TO COMMISSION;
```

```
SELECT JOB_ID, COMMISSION FROM JOBS_Temp WHERE MAX_SALARY > 20000;
```

```

JOB_ID      COMMISSION
-----  -----
AD_PRES
AD_VP
SA_MAN

```

The following statement drops a single column from the table:

```
ALTER TABLE JOBS_Temp DROP COLUMN DUMMY;
```

The following statement drops multiple columns from the table:

```
ALTER TABLE JOBS_Temp DROP (BONUS, COMMISSION);
```

### Data Encryption: Examples

The following statement encrypts the salary column of the `hr.employees` table using the encryption algorithm AES256. As described in "Semantics" above, you must first enable Transparent Data Encryption:

```
ALTER TABLE employees
    MODIFY (salary ENCRYPT USING 'AES256' 'NOMAC');
```

The following statement adds a new encrypted column `online_acct_pw` to the `oe.customers` table, using the default encryption algorithm AES192. Specifying NO SALT will allow a B-tree index to be created on the column, if desired.

```
ALTER TABLE customers
    ADD (online_acct_pw VARCHAR2(8) ENCRYPT 'NOMAC' NO SALT);
```

The following example decrypts the `customer.online_acct_pw` column:

```
ALTER TABLE customers
    MODIFY (online_acct_pw DECRYPT);
```

### Allocating Extents: Example

The following statement allocates an extent of 5 kilobytes for the `employees` table and makes it available to instance 4:

```
ALTER TABLE employees
    ALLOCATE EXTENT (SIZE 5K INSTANCE 4);
```

Because this statement omits the `DATAFILE` parameter, Oracle Database allocates the extent in one of the data files belonging to the tablespace containing the table.

### Specifying a Default Column Value: Examples

This statement modifies the `min_price` column of the `product_information` table so that it has a default value of 10:

```
ALTER TABLE product_information
    MODIFY (min_price DEFAULT 10);
```

If you subsequently add a new row to the `product_information` table and do not specify a value for the `min_price` column, then the value of the `min_price` column is automatically 10:

```
INSERT INTO product_information (product_id, product_name,
    list_price)
VALUES (300, 'left-handed mouse', 40.50);

SELECT product_id, product_name, list_price, min_price
    FROM product_information
    WHERE product_id = 300;

PRODUCT_ID PRODUCT_NAME      LIST_PRICE  MIN_PRICE
----- -----
300      left-handed mouse      40.5          10
```

To discontinue previously specified default values, so that they are no longer automatically inserted into newly added rows, replace the values with `NULL`, as shown in this statement:

```
ALTER TABLE product_information
    MODIFY (min_price DEFAULT NULL);
```

The `MODIFY` clause need only specify the column name and the modified part of the definition, rather than the entire column definition. This statement has no effect on any existing values in existing rows.

The following example adds a column defined with `DEFAULT ON NULL` to a table. The `DEFAULT` column value includes the sequence pseudocolumn `NEXTVAL`.

Create sequence `s1` and table `t1` as follows:

```
CREATE SEQUENCE s1 START WITH 1;

CREATE TABLE t1 (name VARCHAR2(10));
INSERT INTO t1 VALUES('Kevin');
INSERT INTO t1 VALUES('Julia');
INSERT INTO t1 VALUES('Ryan');
```

Add column `id`, which defaults to `s1.NEXTVAL`. The default column value for `id` is assigned to each existing row in the table. The order in which `s1.NEXTVAL` is assigned to each row is nondeterministic.

```
ALTER TABLE t1 ADD (id NUMBER DEFAULT ON NULL s1.NEXTVAL NOT NULL);

SELECT id, name FROM t1 ORDER BY id;
```

ID	NAME
1	Kevin
2	Julia
3	Ryan

If you subsequently add a new row to the table and specify a `NULL` value for the `id` column, then the `DEFAULT ON NULL` expression `s1.NEXTVAL` is inserted.

```
INSERT INTO t1(id, name) VALUES(NULL, 'Sean');

SELECT id, name FROM t1 ORDER BY id;

| ID | NAME  |
|----|-------|
| 1  | Kevin |
| 2  | Julia |
| 3  | Ryan  |
| 4  | Sean  |

```

### Adding a Constraint to an XMLType Table: Example

The following example adds a primary key constraint to the `xwarehouses` table, created in "XMLType Examples":

```
ALTER TABLE xwarehouses
    ADD (PRIMARY KEY(XMLDATA."WarehouseID"));
```

Refer to [XMLDATA Pseudocolumn](#) for information about this pseudocolumn.

### Renaming Constraints: Example

The following statement renames the `cust_fname_nn` constraint on the sample table `oe.customers` to `cust_firstname_nn`:

```
ALTER TABLE customers RENAME CONSTRAINT cust_fname_nn
    TO cust_firstname_nn;
```

### Dropping Constraints: Examples

The following statement drops the primary key of the `departments` table:

```
ALTER TABLE departments
    DROP PRIMARY KEY CASCADE;
```

If you know that the name of the PRIMARY KEY constraint is `pk_dept`, then you could also drop it with the following statement:

```
ALTER TABLE departments
    DROP CONSTRAINT pk_dept CASCADE;
```

The CASCADE clause causes Oracle Database to drop any foreign keys that reference the primary key.

The following statement drops the unique key on the `email` column of the `employees` table:

```
ALTER TABLE employees
    DROP UNIQUE (email);
```

The `DROP` clause in this statement omits the `CASCADE` clause. Because of this omission, Oracle Database does not drop the unique key if any foreign key references it.

### LOB Columns: Examples

The following statement adds CLOB column `resume` to the `employee` table and specifies LOB storage characteristics for the new column:

```
ALTER TABLE employees ADD (resume CLOB)
    LOB (resume) STORE AS resume_seg (TABLESPACE example);
```

To modify the LOB column `resume` to use caching, enter the following statement:

```
ALTER TABLE employees MODIFY LOB (resume) (CACHE);
```

The following statement adds a SecureFiles CLOB column `resume` to the `employee` table and specifies LOB storage characteristics for the new column. SecureFiles LOBs must be stored in tablespaces with automatic segment-space management. Therefore, the LOB data in this example is stored in the `auto_seg_ts` tablespace, which was created in "[Specifying Segment Space Management for a Tablespace: Example](#)".

```
ALTER TABLE employees ADD (resume CLOB)
    LOB (resume) STORE AS SECUREFILE resume_seg (TABLESPACE auto_seg_ts);
```

To modify the LOB column `resume` so that it does not use caching, enter the following statement:

```
ALTER TABLE employees MODIFY LOB (resume) (NOCACHE);
```

### Nested Tables: Examples

The following statement adds the nested table column `skills` to the `employee` table:

```
ALTER TABLE employees ADD (skills skill_table_type)
    NESTED TABLE skills STORE AS nested_skill_table;
```

You can also modify nested table storage characteristics. Use the name of the storage table specified in the `nested_table_col_properties` to make the modification. You cannot query or perform DML statements on the storage table. Use the storage table only to modify the nested table column storage characteristics.

The following statement creates table `vet_service` with nested table column `client` and storage table `client_tab`. Nested table `client_tab` is modified to specify constraints:

```
CREATE TYPE pet_t AS OBJECT
  (pet_id NUMBER, pet_name VARCHAR2(10), pet_dob DATE);
/
CREATE TYPE pet AS TABLE OF pet_t;
/
CREATE TABLE vet_service (vet_name VARCHAR2(30),
  client pet)
  NESTED TABLE client STORE AS client_tab;
ALTER TABLE client_tab ADD UNIQUE (pet_id);
```

The following statement alters the storage table for a nested table of REF values to specify that the REF is scoped:

```
CREATE TYPE emp_t AS OBJECT (eno number, ename char(31));
CREATE TYPE emps_t AS TABLE OF REF emp_t;
CREATE TABLE emptab OF emp_t;
CREATE TABLE dept (dno NUMBER, employees emps_t)
  NESTED TABLE employees STORE AS deptemps;
ALTER TABLE deptemps ADD (SCOPE FOR (COLUMN_VALUE) IS emptab);
```

Similarly, to specify storing the REF with rowid:

```
ALTER TABLE deptemps ADD (REF(column_value) WITH ROWID);
```

In order to execute these ALTER TABLE statements successfully, the storage table `deptemps` must be empty. Also, because the nested table is defined as a table of scalar values (REF values), Oracle Database implicitly provides the column name `COLUMN_VALUE` for the storage table.

### See Also:

- [CREATE TABLE](#) for more information about nested table storage
- [Oracle Database Object-Relational Developer's Guide](#) for more information about nested tables

### REF Columns: Examples

The following statement creates an object type `dept_t` and then creates table `staff`:

```
CREATE TYPE dept_t AS OBJECT
  (deptno NUMBER, dname VARCHAR2(20));
/
CREATE TABLE staff
  (name  VARCHAR2(100),
```

```
salary NUMBER,
dept REF dept_t);
```

An object table `offices` is created as:

```
CREATE TABLE offices OF dept_t;
```

The `dept` column can store references to objects of `dept_t` stored in any table. If you would like to restrict the references to point only to objects stored in the `departments` table, then you could do so by adding a scope constraint on the `dept` column as follows:

```
ALTER TABLE staff
ADD (SCOPE FOR (dept) IS offices);
```

The preceding `ALTER TABLE` statement will succeed only if the `staff` table is empty.

If you want the `REF` values in the `dept` column of `staff` to also store the rowids, then issue the following statement:

```
ALTER TABLE staff
ADD (REF(dept) WITH ROWID);
```

### **Unpacked Storage in ANYDATA Columns: Example**

This example creates a table with an `ANYDATA` column, stores opaque data types in the `ANYDATA` column using unpacked storage, and then queries the data types. This example assumes that you are connected to the database as user `hr`.

Create table `t1`, which contains a `NUMBER` column `n` and an `ANYDATA` column `x`:

```
CREATE TABLE t1 (n NUMBER, x ANYDATA);
```

Create an object type `clob_typ`, which contains a `CLOB` attribute:

```
CREATE OR REPLACE TYPE clob_typ AS OBJECT (c CLOB);
/
```

Enable unpacked storage of the opaque data types `XMLType` and `clob_typ` in `ANYDATA` column `x` of table `t1`:

```
ALTER TABLE t1 MODIFY OPAQUE TYPE x STORE (XMLType, clob_typ) UNPACKED;
```

Insert `XMLType` and `clob_typ` objects into table `t1`. These types will use unpacked storage:

```
INSERT INTO t1
VALUES(1, anydata.convertobject(XMLType('<Test>This is test XML</Test>')));

INSERT INTO t1
VALUES(2, anydata.convertobject(clob_typ(TO_CLOB('This is a test CLOB'))));
```

Query table `t1` to view the names of the types stored in `ANYDATA` column `x`:

```
SELECT t1.* , anydata.getTypeName(t1.x) typename FROM t1;
```

N	X()	TYPENAME
1	ANYDATA()	SYS.XMLTYPE
2	ANYDATA()	HR.CLOB_TYP

Create functions that allow you to query the values stored in the XMLType and clob\_typ data types:

```

CREATE FUNCTION get_xmltype (ad IN ANYDATA) RETURN VARCHAR2 AS
    rtn_val PLS_INTEGER;
    my_xmltype XMLType;
    string_val VARCHAR2(30);
BEGIN
    rtn_val := ad.getObject(my_xmltype);
    string_val := my_xmltype.getstringval();
    return (string_val);
END;
/
CREATE FUNCTION get_clob_typ (ad IN ANYDATA) RETURN VARCHAR2 AS
    rtn_val PLS_INTEGER;
    my_clob_typ clob_typ;
    string_val VARCHAR2(30);
BEGIN
    rtn_val := ad.getObject(my_clob_typ);
    string_val := (my_clob_typ.c);
    return (string_val);
END;
/

```

Query table t1 to view the values stored in each data type in ANYDATA column x:

```

SELECT t1.* , anydata.getTypeName(t1.x) typename,
CASE
    WHEN anydata.gettypename(t1.x) = 'SYS.XMLTYPE' THEN get_xmltype(t1.x)
    WHEN anydata.gettypename(t1.x) = 'HR.CLOB_TYP' THEN get_clob_typ(t1.x)
END string_value
FROM t1;

```

N X()	TYPENAME	STRING_VALUE
1 ANYDATA()	SYS.XMLTYPE	<Test>This is test XML</Test>
2 ANYDATA()	HR.CLOB_TYP	This is a test CLOB

## Additional Examples

For examples of defining integrity constraints with the ALTER TABLE statement, see the [constraint](#).

For examples of changing the storage parameters of a table, see the [storage\\_clause](#).

## Add and Drop Annotations at the Table Level

The following examples use table1:

```
CREATE TABLE table1 (T NUMBER) ANNOTATIONS(Operations 'Sort', Hidden);
```

The following example drops all annotations from table1:

```
ALTER TABLE table1 ANNOTATIONS(DROP Operations, DROP Hidden);
```

The following example adds a new annotation Operations with a JSON value:

```
ALTER TABLE table1 ANNOTATIONS(ADD Operations '["Sort", "Group"]');
```

## Add and Drop Annotations at the Column Level

The following example adds a new Identity annotation for column T of table1:

```
ALTER TABLE table1 MODIFY T ANNOTATIONS(Identity 'ID');
```

The following example adds Hidden, and drops Identity:

```
ALTER TABLE table1 MODIFY T ANNOTATIONS(ADD Hidden, DROP Identity);
```

### Operations on Directory-Based Partitioned Table

#### Example: Create Sharded Table and Partition by Directory

```
CREATE SHARDED TABLE departments
  ( department_id NUMBER(6)
    , department_name VARCHAR2(30) CONSTRAINT dept_name_nn NOT NULL
    , manager_id NUMBER(6)
    , location_id NUMBER(4)
    , CONSTRAINT dept_id_pk PRIMARY KEY(department_id)
  )
PARTITION BY DIRECTORY (department_id)
(
  PARTITION p_1 TABLESPACE tbs1,
  PARTITION p_2 TABLESPACE tbs2
);
```

The following two examples use the table departments above for operations add and split.

#### Add Partitions to a Table Partitioned by Directory

```
ALTER TABLE departments ADD
  PARTITION p_3 TABLESPACE tbs3,
  PARTITION p_4 TABLESPACE tbs4;
```

#### Split Partitions of a Table Partitioned by Directory

```
ALTER TABLE departments
  SPLIT PARTITION p_1 INTO
  (PARTITION p_1 TABLESPACE tbs1,
  PARTITION p_3 TABLESPACE tbs3)
  UPDATE INDEXES;
```

## ALTER TABLESPACE

### Purpose

Use the ALTER TABLESPACE statement to alter an existing tablespace or one or more of its data files or temp files.

You cannot use this statement to convert a dictionary-managed tablespace to a locally managed tablespace. For that purpose, use the DBMS\_SPACE\_ADMIN package, which is documented in *Oracle Database PL/SQL Packages and Types Reference*.

 See Also:

*Oracle Database Administrator's Guide* and [CREATE TABLESPACE](#) for information on creating a tablespace

### Prerequisites

To alter the `SYSAUX` tablespace, you must have the `SYSDBA` system privilege.

If you have the `ALTER TABLESPACE` system privilege, then you can perform any `ALTER TABLESPACE` operation. If you have the `MANAGE TABLESPACE` system privilege, then you can only perform the following operations:

- Take a tablespace online or offline
- Begin or end a backup
- Make a tablespace read only or read write
- Change the state of a tablespace to `PERMANENT` or `TEMPORARY`
- Set the default logging mode of a tablespace to `LOGGING` or `NOLOGGING`
- Put a tablespace in force logging mode or take it out of force logging mode
- Rename a tablespace or a tablespace data file
- Specify `RETENTION GUARANTEE` or `RETENTION NOGUARANTEE` for an undo tablespace
- Resize a data file for a tablespace
- Enable or disable autoextension of a data file for a tablespace
- Shrink the amount of space a temporary tablespace or a temp file is taking

Before you can make a tablespace read only, the following conditions must be met:

- The tablespace must be online.
- The tablespace must not contain any active rollback segments. For this reason, the `SYSTEM` tablespace can never be made read only, because it contains the `SYSTEM` rollback segment. Additionally, because the rollback segments of a read-only tablespace are not accessible, Oracle recommends that you drop the rollback segments before you make a tablespace read only.
- The tablespace must not be involved in an open backup, because the end of a backup updates the header file of all data files in the tablespace.

Performing this function in restricted mode may help you meet these restrictions, because only users with `RESTRICTED SESSION` system privilege can be logged on.

### Syntax

`alter_tablespace ::=`

(`alter_tablespaceAttrs ::=`)

**alter\_tablespace\_attrs ::=**

(*default\_tablespace\_params ::= size\_clause ::= datafile\_tempfile\_clauses ::=,  
 tablespace\_logging\_clauses ::=, tablespace\_group\_clause ::=,  
 tablespace\_state\_clauses ::=, autoextend\_clause ::=, flashback\_mode\_clause ::=,  
 tablespace\_retention\_clause ::=, alter\_tablespace\_encryption ::=,  
 lost\_write\_protection ::=*)

**default\_tablespace\_params ::=**

(*default\_table\_compression ::=—part of CREATE TABLESPACE,  
 default\_index\_compression ::=—part of CREATE TABLESPACE, inmemory\_clause ::=—part  
 of CREATE TABLESPACE, ilm\_clause ::=—part of ALTER TABLE, storage\_clause ::=*)

 **Note:**

If you specify the `DEFAULT` clause, then you must specify at least one of the clauses `default_table_compression`, `default_index_compression`, `inmemory_clause`, `ilm_clause`, or `storage_clause`.

***datafile\_tempfile\_clauses ::=***

(*file\_specification ::=*).

***tablespace\_logging\_clauses ::=***

(*logging\_clause ::=*)

***tablespace\_group\_clause ::=***

*tablespace\_state\_clauses ::=*

*autoextend\_clause ::=*

(*size\_clause ::=*)

*maxsize\_clause ::=*

(*size\_clause ::=*)

*flashback\_mode\_clause ::=*

*tablespace\_retention\_clause ::=*

***alter\_tablespace\_encryption ::=***

(*tablespace\_encryption\_spec ::=*, *ts\_file\_name\_convert ::=*)

***tablespace\_encryption\_spec ::=***

***ts\_file\_name\_convert ::=***

***lost\_write\_protection ::=***

**Semantics**

**IF NOT EXISTS**

Specify **IF EXISTS** to alter an existing tablespace.

Specifying **IF NOT EXISTS** with **ALTER** results in error: Incorrect **IF EXISTS** clause for **ALTER/DROP** statement.

### **tablespace**

Specify the name of the tablespace to be altered.

### **Restrictions on Altering Tablespaces**

Altering tablespaces is subject to the following restrictions:

- If `tablespace` is an undo tablespace, then the only other clauses you can specify in this statement are ADD DATAFILE, RENAME DATAFILE, RENAME TO (renaming the tablespace), DATAFILE ... ONLINE, DATAFILE ... OFFLINE, BEGIN BACKUP, and END BACKUP.
- You cannot make the SYSTEM tablespace read only or temporary and you cannot take it offline.
- For locally managed temporary tablespaces, the only clause you can specify in this statement is the ADD clause.

#### **See Also:**

*Oracle Database Administrator's Guide* for information on automatic undo management and undo tablespaces

### **alter\_tablespace\_attrs**

Use the `alter_tablespace_attrs` clauses to change the attributes of the tablespace.

### **default\_tablespace\_params**

This clause lets you specify new default parameters for the tablespace. The new default parameters apply to objects subsequently created in the tablespace.

The clauses `default_table_compression`, `default_index_compression`, `inmemory_clause`, `ilm_clause`, and `storage_clause` have the same semantics in CREATE TABLESPACE and ALTER TABLESPACE. For complete information on these clauses, refer to the [default\\_tablespace\\_params](#) clause in the documentation on CREATE TABLESPACE.

### **MINIMUM EXTENT**

This clause is valid only for permanent dictionary-managed tablespaces. The `MINIMUM EXTENT` clause lets you control free space fragmentation in the tablespace by ensuring that every used or free extent in a tablespace is at least as large as, and is a multiple of, the value specified in the `size_clause`.

### **Restriction on MINIMUM EXTENT**

You cannot specify this clause for a locally managed tablespace or for a dictionary-managed temporary tablespace.

 **See Also:**

[size\\_clause](#) for information about that clause, *Oracle Database Administrator's Guide* for more information about using `MINIMUM EXTENT` to control space fragmentation

**RESIZE Clause**

This clause is valid only for bigfile tablespaces, including shadow tablespaces which store lost write protection tracking data. It lets you increase or decrease the size of the single data file to an absolute size. Use K, M, G, or T to specify the size in kilobytes, megabytes, gigabytes, or terabytes, respectively.

To change the size of a newly added data file or temp file in smallfile tablespaces, use the `ALTER DATABASE ... autoextend_clause` (see [database\\_file\\_clauses](#) ).

 **See Also:**

[BIGFILE | SMALLFILE](#) for information on bigfile tablespaces

**COALESCE**

For each data file in the tablespace, this clause combines all contiguous free extents into larger contiguous extents.

**SHRINK SPACE Clause**

This clause is valid only for temporary tablespaces. It lets you reduce the amount of space the tablespace is taking. In the optional `KEEP` clause, the `size_clause` defines the lower bound that a tablespace can be shrunk to. It is the opposite of `MAXSIZE` for an autoextensible tablespace. If you omit the `KEEP` clause, then the database will attempt to shrink the tablespace as much as possible as long as other tablespace storage attributes are satisfied.

**RENAME Clause**

Use this clause to rename `tablespace`. This clause is valid only if `tablespace` and all its data files are online and the `COMPATIBLE` parameter is set to 10.0.0 or greater. You can rename both permanent and temporary tablespaces.

If `tablespace` is read only, then Oracle Database does not update the data file headers to reflect the new name. The alert log will indicate that the data file headers have not been updated.

 **Note:**

If you re-create the control file, and if the data files that Oracle Database uses for this purpose are restored backups whose headers reflect the old tablespace name, then the re-created control file will also reflect the old tablespace name. However, after the database is fully recovered, the control file will reflect the new name.

If `tablespace` has been designated as the undo tablespace for any instance in an Oracle Real Application Clusters (Oracle RAC) environment, and if a server parameter file was used to start up the database, then Oracle Database changes the value of the `UNDO_TABLESPACE` parameter for that instance in the server parameter file (SPFILE) to reflect the new tablespace name. If a single-instance database is using a parameter file (pfile) instead of an spfile, then the database puts a message in the alert log advising the database administrator to change the value manually in the pfile.

#### Note:

The `RENAME` clause does not change the value of the `UNDO_TABLESPACE` parameter in the running instance. Although this does not affect the functioning of the undo tablespace, Oracle recommends that you issue the following statement to manually change the value of `UNDO_TABLESPACE` to the new tablespace name for the duration of the instance:

```
ALTER SYSTEM SET UNDO_TABLESPACE = new_tablespace_name SCOPE = MEMORY;
```

You only need to issue this statement once. If the `UNDO_TABLESPACE` parameter is set to the new tablespace name in the pfile or spfile, then the parameter will be set correctly when the instance is next restarted.

### Restriction on Renaming Tablespaces

You cannot rename the `SYSTEM` or `SYSAUX` tablespaces.

### BACKUP Clauses

Use these clauses to move all data files in a tablespace into or out of online (sometimes called hot) backup mode.

#### See Also:

- *Oracle Database Administrator's Guide* for information on restarting the database without media recovery
- `ALTER DATABASE "BACKUP Clauses"` for information on moving all data files in the database into and out of online backup mode
- `ALTER DATABASE alter_datafile_clause` for information on taking individual data files out of online backup mode

### BEGIN BACKUP

Specify `BEGIN BACKUP` to indicate that an open backup is to be performed on the data files that make up this tablespace. This clause does not prevent users from accessing the tablespace. You must use this clause before beginning an open backup.

### Restrictions on Beginning Tablespace Backup

Beginning tablespace backup is subject to the following restrictions:

- You cannot specify this clause for a read-only tablespace or for a temporary locally managed tablespace.
- While the backup is in progress, you cannot take the tablespace offline normally, shut down the instance, or begin another backup of the tablespace.

 **See Also:**

"[Backing Up Tablespaces: Examples](#)"

## END BACKUP

Specify `END BACKUP` to indicate that an online backup of the tablespace is complete. Use this clause as soon as possible after completing an online backup. Otherwise, if an instance failure or `SHUTDOWN ABORT` occurs, then Oracle Database assumes that media recovery (possibly requiring archived redo log) is necessary at the next instance startup.

### Restriction on Ending Tablespace Backup

You cannot use this clause on a read-only tablespace.

### `datafile_tempfile_clauses`

The tablespace file clauses let you add or modify a data file or temp file.

### ADD Clause

Specify `ADD` to add to the tablespace a data file or temp file specified by `file_specification`. Use the `datafile_tempfile_spec` form of `file_specification` (see [file\\_specification](#)) to list regular data files and temp files in an operating system file system or to list Oracle Automatic Storage Management disk group files.

For locally managed temporary tablespaces, this is the only clause you can specify at any time.

If you omit `file_specification`, then Oracle Database creates an Oracle Managed File of 100M with `AUTOEXTEND` enabled.

You can add a data file or temp file to a locally managed tablespace that is online or to a dictionary managed tablespace that is online or offline. Ensure the file is not in use by another database.

### Restriction on Adding Data Files and Temp Files

You cannot specify this clause for a bigfile (single-file) tablespace, as such a tablespace has only one data file or temp file.

 **Note:**

On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.

 **See Also:**

[file\\_specification](#), "Adding and Dropping Data Files and Temp Files: Examples", and "[Adding an Oracle-managed Data File: Example](#)"

### DROP Clause

Specify `DROP` to drop from the tablespace an empty data file or temp file specified by `filename` or `file_number`. This clause causes the data file or temp file to be removed from the data dictionary and deleted from the operating system. The database must be open at the time this clause is specified.

The `ALTER TABLESPACE ... DROP TEMPFILE` statement is equivalent to specifying the `ALTER DATABASE TEMPFILE ... DROP INCLUDING DATAFILES`.

### Restrictions on Dropping Files

To drop a data file or temp file, the data file or temp file:

- Must be empty.
- Cannot be the first data file that was created in the tablespace. In such cases, drop the tablespace instead.
- Cannot be in a read-only tablespace that was migrated from dictionary managed to locally managed. Dropping a data file from all other read-only tablespaces is supported.
- Cannot be offline.

 **See Also:**

- `ALTER DATABASE alter_tempfile_clause` for additional information on dropping temp files
- *Oracle Database Administrator's Guide* for information on data file numbers and for guidelines on managing data files
- "[Adding and Dropping Data Files and Temp Files: Examples](#)"

### SHRINK TEMPFILE Clause

This clause is valid only when altering a temporary tablespace. It lets you reduce the amount of space the specified temp file is taking. In the optional `KEEP` clause, the `size_clause` defines the lower bound that the temp file can be shrunk to. It is the opposite of `MAXSIZE` for an autoextensible tablespace. If you omit the `KEEP` clause, then the database will attempt to shrink the temp file as much as possible as long as other storage attributes are satisfied.

### RENAME DATAFILE Clause

Specify `RENAME DATAFILE` to rename one or more of the tablespace data files. The database must be open, and you must take the tablespace offline before renaming it. Each `filename` must fully specify a data file using the conventions for filenames on your operating system.

This clause merely associates the tablespace with the new file rather than the old one. This clause does not actually change the name of the operating system file. You must change the name of the file through your operating system.

#### See Also:

["Moving and Renaming Tablespaces: Example"](#)

### ONLINE | OFFLINE Clauses

Use these clauses to take all data files or temp files in the tablespace offline or put them online. These clauses have no effect on the `ONLINE` or `OFFLINE` status of the tablespace itself.

The database must be mounted. If `tablespace` is `SYSTEM`, or an undo tablespace, or the default temporary tablespace, then the database must not be open.

#### `tablespace_logging_clauses`

Use these clauses to set or change the logging characteristics of the tablespace.

##### `logging_clause`

Specify `LOGGING` if you want logging of all tables, indexes, and partitions within the tablespace. The tablespace-level logging attribute can be overridden by logging specifications at the table, index, and partition levels.

When an existing tablespace logging attribute is changed by an `ALTER TABLESPACE` statement, all tables, indexes, and partitions created *after* the statement will have the new default logging attribute (which you can still subsequently override). The logging attribute of existing objects is not changed.

If the tablespace is in `FORCE LOGGING` mode, then you can specify `NOLOGGING` in this statement to set the default logging mode of the tablespace to `NOLOGGING`, but this will not take the tablespace out of `FORCE LOGGING` mode.

##### [NO] FORCE LOGGING

Use this clause to put the tablespace in force logging mode or take it out of force logging mode. The database must be open and in `READ WRITE` mode. Neither of these settings changes the default `LOGGING` or `NOLOGGING` mode of the tablespace.

##### Restriction on Force Logging Mode

You cannot specify FORCE LOGGING for an undo or a temporary tablespace.

 **See Also:**

*Oracle Database Administrator's Guide* for information on when to use FORCE LOGGING mode and "["Changing Tablespace Logging Attributes: Example"](#)

#### ***tablespace\_group\_clause***

This clause is valid only for locally managed temporary tablespaces. Use this clause to add *tablespace* to or remove it from the *tablespace\_group\_name* tablespace group.

- Specify a group name to indicate that *tablespace* is a member of this tablespace group. If *tablespace\_group\_name* does not already exist, then Oracle Database implicitly creates it when you alter tablespace to be a member of it.
- Specify an empty string (' ') to remove *tablespace* from the *tablespace\_group\_name* tablespace group.

#### **Restriction on Tablespace Groups**

You cannot specify a tablespace group for a permanent tablespace or for a dictionary-managed temporary tablespace.

 **See Also:**

*Oracle Database Administrator's Guide* for more information on tablespace groups and "["Assigning a Tablespace Group: Example"](#)

#### ***tablespace\_state\_clauses***

Use these clauses to set or change the state of the tablespace.

##### **ONLINE | OFFLINE**

Specify ONLINE to bring the tablespace online. Specify OFFLINE to take the tablespace offline and prevent further access to its segments. When you take a tablespace offline, all of its data files are also offline.

 **Note:**

Before taking a tablespace offline for a long time, consider changing the tablespace allocation of any users who have been assigned the tablespace as either a default or temporary tablespace. While the tablespace is offline, such users cannot allocate space for objects or sort areas in the tablespace. See [ALTER USER](#) for more information on allocating tablespace quota to users.

#### **Restriction on Taking Tablespaces Offline**

You cannot take a temporary tablespace offline.

#### OFFLINE NORMAL

Specify `NORMAL` to flush all blocks in all data files in the tablespace out of the system global area (SGA). You need not perform media recovery on this tablespace before bringing it back online. This is the default.

#### OFFLINE TEMPORARY

If you specify `TEMPORARY`, then Oracle Database performs a checkpoint for all online data files in the tablespace but does not ensure that all files can be written. Files that are offline when you issue this statement may require media recovery before you bring the tablespace back online.

#### OFFLINE IMMEDIATE

If you specify `IMMEDIATE`, then Oracle Database does not ensure that tablespace files are available and does not perform a checkpoint. You must perform media recovery on the tablespace before bringing it back online.

##### Note:

The `FOR RECOVER` setting for `ALTER TABLESPACE ... OFFLINE` has been deprecated. The syntax is supported for backward compatibility. However, Oracle recommends that you use the transportable tablespaces feature for tablespace recovery.

##### See Also:

*Oracle Database Backup and Recovery User's Guide* for information on using transportable tablespaces to perform media recovery

#### READ ONLY | READ WRITE

Specify `READ ONLY` to place the tablespace in **transition read-only mode**. In this state, existing transactions can complete (commit or roll back), but no further DML operations are allowed to the tablespace except for rollback of existing transactions that previously modified blocks in the tablespace. You cannot make the `SYSAUX`, `SYSTEM`, or temporary tablespaces `READ ONLY`.

When a tablespace is read only, you can copy its files to read-only media. You must then rename the data files in the control file to point to the new location by using the SQL statement `ALTER DATABASE ... RENAME`.

##### See Also:

- *Oracle Database Concepts* for more information on read-only tablespaces
- [ALTER DATABASE](#)

Specify `READ WRITE` to indicate that write operations are allowed on a previously read-only tablespace.

#### **PERMANENT | TEMPORARY**

Specify `PERMANENT` to indicate that the tablespace is to be converted from a temporary to a permanent tablespace. A permanent tablespace is one in which permanent database objects can be stored. This is the default when a tablespace is created.

Specify `TEMPORARY` to indicate that the tablespace is to be converted from a permanent to a temporary tablespace. A temporary tablespace is one in which no permanent database objects can be stored. Objects in a temporary tablespace persist only for the duration of the session.

#### **Restrictions on Temporary Tablespaces**

Temporary tablespaces are subject to the following restrictions:

- You cannot specify `TEMPORARY` for the `SYSAUX` tablespace.
- If `tablespace` was not created with a standard block size, then you cannot change it from permanent to temporary.
- You cannot specify `TEMPORARY` for a tablespace in `FORCE LOGGING` mode.

#### ***autoextend\_clause***

This clause is valid only for bigfile (single-file) tablespaces. Use this clause to enable or disable autoextension of the single data file in the tablespace. To enable or disable autoextension of a newly added data file or temp file in smallfile tablespaces, use the `autoextend_clause` of the [database\\_file\\_clauses](#) in the `ALTER DATABASE` statement.

#### **See Also:**

- [Oracle Database Administrator's Guide](#) for information about bigfile (single-file) tablespaces
- [`file\_specification`](#) for more information about the `autoextend_clause`

#### ***flashback\_mode\_clause***

Use this clause to specify whether this tablespace should participate in any subsequent `FLASHBACK DATABASE` operation.

- For you to turn `FLASHBACK` mode on, the database must be mounted and closed.
- For you to turn `FLASHBACK` mode off, the database must be mounted, either open `READ WRITE` or closed.

This clause is not valid for temporary tablespaces.

Refer to [CREATE TABLESPACE](#) for more complete information on this clause.

 **See Also:**

*Oracle Database Backup and Recovery User's Guide* for more information about Flashback Database

***tablespace\_retention\_clause***

This clause has the same semantics in CREATE TABLESPACE and ALTER TABLESPACE statements. Refer to [tablespace\\_retention\\_clause](#) in the documentation on CREATE TABLESPACE.

***alter\_tablespace\_encryption***

These clauses let you encrypt, decrypt, or rekey the tablespace.

ONLINE is the default for ALTER TABLESPACE ENCRYPTION.

**ONLINE**

- Specify ENCRYPT to encrypt the tablespace. The tablespace must be unencrypted.
- Specify REKEY to encrypt an encrypted tablespace using a different encryption algorithm. The tablespace must have been encrypted when it was created or encrypted with online conversion (ONLINE ENCRYPT).
- Specify DECRYPT to decrypt the tablespace. The tablespace must have been encrypted when it was created or encrypted with online conversion (ONLINE ENCRYPT).

**FINISH**

If an online conversion operation is interrupted, use the FINISH clause to finish the operation. The ENCRYPT, DECRYPT, REKEY, and *ts\_file\_name\_convert* clauses have the same semantics here as they have for the ONLINE clause.

You can use FINISH to encrypt, decrypt, or rekey the tablespace with online conversion. The tablespace must be online. The online conversion method creates a new datafile for each datafile in the tablespace. Therefore, before using this clause, ensure that the amount of free disk space is greater than or equal to the amount of disk space currently used by the tablespace.

**OFFLINE**

This clause lets you encrypt or decrypt the tablespace with offline conversion. The tablespace must be offline or the database must be mounted, but not open. The offline conversion method does not use auxiliary disk space or files; it operates directly on the existing datafiles. Therefore, you should perform a full backup of the tablespace before converting it offline.

- Specify ENCRYPT to encrypt the tablespace. You can encrypt the tablespace using AES128, AES192, or AES256 algorithms. The tablespace must be unencrypted.
- Specify DECRYPT to decrypt the tablespace. The tablespace must have been previously encrypted with offline conversion (OFFLINE ENCRYPT).

If an offline conversion operation is interrupted, then you can reissue the offline conversion command to finish the operation.

***tablespace\_encryption\_spec***

Use this clause to specify the encryption algorithm to use when encrypting or rekeying the tablespace. If you omit this clause, then the datafiles will be encrypted using the AES128 algorithm. Refer to [tablespace\\_encryption\\_spec](#) in the documentation on CREATE TABLESPACE for the full semantics of this clause.

#### ***ts\_file\_name\_convert***

Use this clause to determine how the database generates the names of the new datafiles that are created during online conversion.

If FILE\_NAME\_CONVERT is omitted, Oracle will internally select a name for the auxiliary file, and later rename it back to the original name.

- For *filename\_pattern*, specify a string found in an existing datafile name.
- For *replacement\_filename\_pattern*, specify a replacement string. Oracle Database will replace *filename\_pattern* with *replacement\_filename\_pattern* when naming the new datafile.
- Specify KEEP to retain the original files after the tablespace conversion is finished. If you omit this clause, then the original files are deleted when the conversion is finished.

#### **Restriction on the *alter\_tablespace\_encryption* Clause**

You cannot perform offline or online conversions on temporary tablespaces.

#### ***lost\_write\_protection***

Before you can enable lost write protection on individual tablespaces, you must first enable the database for shadow lost write protection with ALTER DATABASE. Then you must create at least one shadow tablespace in that database using the CREATE TABLESPACE command.

After these steps you can use ALTER TABLESPACE to enable, remove, and suspend lost write protection on the shadow tablespace.

#### **Example: Enable Lost Write Protection for a Tablespace**

The following command enables lost write protection for the tbsu1 tablespace.

```
ALTER TABLESPACE tbsu1 ENABLE LOST WRITE PROTECTION
```

#### **Example: Remove Lost Write Protection for a Shadow Tablespace**

The following command removes lost write protection for the tbsu1 tablespace.

```
ALTER TABLESPACE tbsu1 REMOVE LOST WRITE PROTECTION
```

#### **Example: Suspend Lost Write Protection for a Shadow Tablespace**

The following command suspends lost write protection for the tbsu1 tablespace.

```
ALTER TABLESPACE tbsu1 SUSPEND LOST WRITE PROTECTION
```

#### **See Also:**

*Managing Lost Write Protection with Shadow Tablespaces*

## Examples

### Backing Up Tablespaces: Examples

The following statement signals to the database that a backup is about to begin:

```
ALTER TABLESPACE tbs_01
  BEGIN BACKUP;
```

The following statement signals to the database that the backup is finished:

```
ALTER TABLESPACE tbs_01
  END BACKUP;
```

### Moving and Renaming Tablespaces: Example

This example moves and renames a data file associated with the `tbs_02` tablespace, created in "[Enabling Autoextend for a Tablespace: Example](#)", from `diskb:tbs_f5.dbf` to `diska:tbs_f5.dbf`:

1. Take the tablespace offline using an `ALTER TABLESPACE` statement with the `OFFLINE` clause:

```
ALTER TABLESPACE tbs_02 OFFLINE NORMAL;
```

2. Copy the file from `diskb:tbs_f5.dbf` to `diska:tbs_f5.dbf` using your operating system commands.

3. Rename the data file using an `ALTER TABLESPACE` statement with the `RENAME DATAFILE` clause:

```
ALTER TABLESPACE tbs_02
  RENAME DATAFILE 'diskb:tbs_f5.dbf'
    TO          'diska:tbs_f5.dbf';
```

4. Bring the tablespace back online using an `ALTER TABLESPACE` statement with the `ONLINE` clause:

```
ALTER TABLESPACE tbs_02 ONLINE;
```

### Adding and Dropping Data Files and Temp Files: Examples

The following statement adds a data file to the tablespace. When more space is needed, new 10-kilobytes extents will be added up to a maximum of 100 kilobytes:

```
ALTER TABLESPACE tbs_03
  ADD DATAFILE 'tbs_f04.dbf'
  SIZE 100K
  AUTOEXTEND ON
  NEXT 10K
  MAXSIZE 100K;
```

The following statement drops the empty data file:

```
ALTER TABLESPACE tbs_03
  DROP DATAFILE 'tbs_f04.dbf';
```

The following statements add a temp file to the temporary tablespace created in "[Creating a Temporary Tablespace: Example](#)" and then drops the temp file:

```
ALTER TABLESPACE temp_demo ADD TEMPFILE 'temp05.dbf' SIZE 5 AUTOEXTEND ON;
```

```
ALTER TABLESPACE temp_demo DROP TEMPFILE 'temp05.dbf';
```

### Managing Space in a Temporary Tablespace: Example

The following statement manages the space in the temporary tablespace created in "[Creating a Temporary Tablespace: Example](#)" using the `SHRINK SPACE` clause. The `KEEP` clause is omitted, so the database will attempt to shrink the tablespace as much as possible as long as other tablespace storage attributes are satisfied.

```
ALTER TABLESPACE temp_demo SHRINK SPACE;
```

### Adding an Oracle-managed Data File: Example

The following example adds an Oracle-managed data file to the `omf_ts1` tablespace (see "[Creating Oracle Managed Files: Examples](#)" for the creation of this tablespace). The new data file is 100M and is autoextensible with unlimited maximum size:

```
ALTER TABLESPACE omf_ts1 ADD DATAFILE;
```

### Changing Tablespace Logging Attributes: Example

The following example changes the default logging attribute of a tablespace to `NOLOGGING`:

```
ALTER TABLESPACE tbs_03 NOLOGGING;
```

Altering a tablespace logging attribute has no affect on the logging attributes of the existing schema objects within the tablespace. The tablespace-level logging attribute can be overridden by logging specifications at the table, index, and partition levels.

### Changing Undo Data Retention: Examples

The following statement changes the undo data retention for tablespace `undots1` to normal undo data behavior:

```
ALTER TABLESPACE undots1
  RETENTION NOGUARANTEE;
```

The following statement changes the undo data retention for tablespace `undots1` to behavior that preserves unexpired undo data:

```
ALTER TABLESPACE undots1
  RETENTION GUARANTEE;
```

## ALTER TABLESPACE SET

### Note:

This SQL statement is valid only if you are using Oracle Sharding. For more information on Oracle Sharding, refer to *Oracle Database Administrator's Guide*.

### Purpose

Use the `ALTER TABLESPACE SET` statement to change an attribute of an existing tablespace set. The attribute change is applied to all tablespaces in the tablespace set.

 See Also:

[CREATE TABLESPACE SET](#) and [DROP TABLESPACE SET](#)

## Prerequisites

You must be connected to a shard catalog database as an SDB user.

If you have the `ALTER TABLESPACE` system privilege, then you can perform any `ALTER TABLESPACE SET` operation. If you have the `MANAGE TABLESPACE` system privilege, then you can only perform the following operations:

- Take all tablespaces in a tablespace set online or offline
- Begin or end a backup
- Make all tablespaces in a tablespace set read only or read write
- Set the default logging mode of all tablespaces in a tablespace set to `LOGGING` or `NOLOGGING`
- Put all tablespaces in a tablespace set in force logging mode or take them out of force logging mode
- Resize all data files for a tablespace set
- Enable or disable autoextension of all data files for a tablespace set

Before you can make a tablespace set read only, the following conditions must be met:

- The tablespaces in the tablespace set must be online.
- The tablespace set must not contain any active rollback segments. Additionally, because the rollback segments of a read-only tablespace set are not accessible, Oracle recommends that you drop the rollback segments before you make a tablespace set read only.
- The tablespace set must not be involved in an open backup, because the end of a backup updates the header file of all data files in the tablespace set.

## Syntax

`alter_tablespace_set ::=`

***alter\_tablespace\_attrs ::=***

(See the following clauses of ALTER TABLESPACE: [default\\_tablespace\\_params::=](#), [size\\_clause::=](#), [datafile\\_tempfile\\_clauses::=](#), [tablespace\\_logging\\_clauses::=](#), [tablespace\\_state\\_clauses::=](#), [autoextend\\_clause::=](#), [alter\\_tablespace\\_encryption::=](#))

### Semantics

#### ***tablespace\_set***

Specify the name of the tablespace set to be altered.

#### ***alter\_tablespaceAttrs***

Use this clause to change an attribute for all tablespaces in the tablespace set.

The subclauses of *alter\_tablespaceAttrs* have the same semantics here as for the ALTER TABLESPACE statement, with the following exceptions:

- You cannot specify the following subclauses for tablespace sets:
  - MINIMUM EXTENT *size\_clause*
  - SHRINK SPACE [ KEEP *size\_clause* ]
  - *tablespace\_group\_clause*

- *flashback\_mode\_clause*
- *tablespace\_retention\_clause*
- For the *datafile\_tempfile\_clauses*, only the following subclauses are supported for tablespace sets:
  - RENAME DATAFILE
  - DATAFILE { ONLINE | OFFLINE }
- For the *tablespace\_state\_clauses*, the PERMANENT and TEMPORARY subclauses are not supported for tablespace sets.

 **See Also:**

[alter\\_tablespaceAttrs](#) in the documentation on ALTER TABLESPACE for the full semantics of this clause

## Examples

### Altering a Tablespace Set: Example

The following statement puts all tablespaces in tablespace set `ts1` in force logging mode:

```
ALTER TABLESPACE SET ts1
  FORCE LOGGING;
```

# ALTER TRIGGER

## Purpose

Triggers are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `ALTER TRIGGER` statement to enable, disable, or compile a database trigger.

 **Note:**

This statement does not change the declaration or definition of an existing trigger. To redeclare or redefine a trigger, use the `CREATE TRIGGER` statement with the `OR REPLACE` keywords.

 **See Also:**

- [CREATE TRIGGER](#) for information on creating a trigger
- [DROP TRIGGER](#) for information on dropping a trigger
- *Oracle Database Concepts* for general information on triggers

## Prerequisites

The trigger must be in your own schema or you must have ALTER ANY TRIGGER system privilege.

In addition, to alter a trigger on DATABASE, you must have the ADMINISTER DATABASE TRIGGER privilege.

 **See Also:**

[CREATE TRIGGER](#) for more information on triggers based on DATABASE triggers

## Syntax

***alter\_trigger ::=***

(*trigger\_compile\_clause*: See *Oracle Database PL/SQL Language Reference* for the syntax of this clause.)

## Semantics

### IF EXISTS

Specify IF EXISTS to alter an existing table.

Specifying IF NOT EXISTS with ALTER VIEW results in ORA-11544: Incorrect IF EXISTS clause for ALTER/DROP statement.

### schema

Specify the schema containing the trigger. If you omit *schema*, then Oracle Database assumes the trigger is in your own schema.

### trigger\_name

Specify the name of the trigger to be altered.

### trigger\_compile\_clause

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling triggers.

### ENABLE | DISABLE

Specify `ENABLE` to enable the trigger. You can also use the `ENABLE ALL TRIGGERS` clause of `ALTER TABLE` to enable all triggers associated with a table. See [ALTER TABLE](#).

Specify `DISABLE` to disable the trigger. You can also use the `DISABLE ALL TRIGGERS` clause of `ALTER TABLE` to disable all triggers associated with a table.

### RENAME Clause

Specify `RENAME TO new_name` to rename the trigger. Oracle Database renames the trigger and leaves it in the same state it was in before being renamed.

When you rename a trigger, the database rebuilds the remembered source of the trigger in the `USER_SOURCE`, `ALL_SOURCE`, and `DBA_SOURCE` data dictionary views. As a result, comments and formatting may change in the `TEXT` column of those views even though the trigger source did not change.

### EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the trigger becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `TRIGGER` in `schema`. The default is `EDITIONABLE`. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

### Restriction on NONEDITIONABLE

You cannot specify `NONEDITIONABLE` for a crossedition trigger.

## ALTER TYPE

### Purpose

Object types are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `ALTER TYPE` statement to add or drop member attributes or methods. You can change the existing properties (`FINAL` or `INSTANTIABLE`) of an object type, and you can modify the scalar attributes of the type.

You can also use this statement to recompile the specification or body of the type or to change the specification of an object type by adding new object member subprogram specifications.

### Prerequisites

The object type must be in your own schema and you must have `CREATE TYPE` or `CREATE ANY TYPE` system privilege, or you must have `ALTER ANY TYPE` system privileges.

## Syntax

**alter\_type ::=**

(*alter\_type\_clause*: See *Oracle Database PL/SQL Language Reference* for the syntax of this clause.)

## Semantics

### IF EXISTS

Specify **IF EXISTS** to alter an existing table.

Specifying **IF NOT EXISTS** with **ALTER VIEW** results in ORA-11544: Incorrect **IF EXISTS** clause for **ALTER/DROP** statement.

### schema

Specify the schema that contains the type. If you omit *schema*, then Oracle Database assumes the type is in your current schema.

### type\_name

Specify the name of an object type, a nested table type, or a varray type.

### Restriction on type\_name

You cannot evolve an editioned object type. The **ALTER TYPE** statement fails with ORA-22348 if either of the following is true:

- The type is an editioned object type and the **ALTER TYPE** statement has no *type\_compile\_clause*. You can use the **ALTER TYPE** statement to recompile an editioned object type, but not for any other purpose.
- The type has a dependent that is an editioned object type and the **ALTER TYPE** statement has a **CASCADE** clause.

Refer to *Oracle Database PL/SQL Language Reference* for more information on the *type\_compile\_clause* and the **CASCADE** clause.

### alter\_type\_clause

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of this clause and for complete information on creating and compiling object types.

### EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the type becomes an editioned or noneditioned object if editioning is later enabled for the schema object type **TYPE** in *schema*. The default is **EDITIONABLE**. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

# ALTER USER

## Purpose

Use the `ALTER USER` statement:

- To change the authentication or database resource characteristics of a database user
- To permit a proxy server to connect as a client without authentication
- In an Oracle Automatic Storage Management (Oracle ASM) cluster, to change the password of a user in the password file that is local to the Oracle ASM instance of the current node

### See Also:

*Oracle Database Security Guide* for detailed information about user authentication methods

## Prerequisites

In general, you must have the `ALTER USER` system privilege. However, the current user can change his or her own password without this privilege.

To change the `SYS` password, password file must exist, and an account granted `alter user` privilege must have the `SYSDBA` administrative role in order to have the ability to change `SYS` password.

You must be authenticated `AS SYSASM` to change the password of a user other than yourself in an Oracle ASM instance password file.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). If the current container is the root, then you can specify `CONTAINER = ALL` or `CONTAINER = CURRENT`. If the current container is a pluggable database (PDB), then you can specify only `CONTAINER = CURRENT`.

To set and modify `CONTAINER_DATA` attributes using the `container_data_clause`, you must be connected to a CDB and the current container must be the root.

## Syntax

*alter\_user*::=

(size\_clause::=)

### ***container\_data\_clause::=***

*proxy\_clause*::=

## ***db\_user\_proxy\_clauses ::=***

## Semantics

The keywords, parameters, and clauses described in this section are unique to `ALTER USER` or have different semantics than they have in `CREATE USER`. Keywords, parameters, and clauses that do not appear here have the same meaning as in the `CREATE USER` statement.

**Note:**

Oracle recommends that user names and passwords be encoded in ASCII or EBCDIC characters only, depending on your platform.

**See Also:**

[CREATE USER](#) for information on the keywords and parameters and [CREATE PROFILE](#) for information on assigning limits on database resources to a user

**IF EXISTS**

Specify `IF EXISTS` to alter an existing table.

Specifying `IF NOT EXISTS` with `ALTER VIEW` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

**IDENTIFIED Clause****BY *password***

Specify `BY password` to specify a new password for the user. Passwords are case sensitive. Any subsequent `CONNECT` string used to connect this user to the database must specify the password using the same case (upper, lower, or mixed) that is used in this `ALTER USER` statement. Passwords can contain single-byte, or multibyte characters, or both from your database character set.

**Note:**

Oracle Database expects a different timestamp for each resetting of a particular password. If you reset one password multiple times within one second (for example, by cycling through a set of passwords using a script), then the database may return an error message that the password cannot be reused. For this reason, Oracle recommends that you avoid using scripts to reset passwords.

You can omit the `REPLACE` clause if you are setting your own password or you have the `ALTER USER` system privilege and you are changing another user's password. However, unless you have the `ALTER USER` system privilege, you must always specify the `REPLACE` clause if a password complexity verification function has been enabled, either by running the `UTLPWDMG.SQL` script or by specifying such a function in the `PASSWORD_VERIFY_FUNCTION` parameter of a profile that has been assigned to the user.

In an Oracle ASM cluster, you can use this clause to change the password of a user in the password file that is local to an Oracle ASM instance of the current node. You must be authenticated AS `SYSASM` to specify `IDENTIFIED BY password` without the `REPLACE`

*old\_password* clause. If you are not authenticated AS SYSASM, then you can only change your own password by specifying REPLACE *old\_password*.

Oracle Database does not check the old password, even if you provide it in the REPLACE clause, unless you are changing your own existing password.

### Changing a Password to Begin the Gradual Database Password Rollover Period

#### Prerequisite

Enable gradual database password rollover period by setting a non-zero value to the PASSWORD\_ROLLOVER\_TIME user profile parameter using CREATE PROFILE or ALTER PROFILE .

After you set the PASSWORD\_ROLLOVER\_TIME to specify the duration of the gradual password rollover period in the profile of the user, you can use the ALTER USER statement to change the user's password, which will allow clients to login using both the old password and the new password until the password rollover period expires.

During the password rollover period, you must propagate the new password to all clients (before the PASSWORD\_ROLLOVER\_TIME ends). If you successfully propagated the new password to all clients early (before the end of the password rollover period), then you can use the EXPIRE PASSWORD ROLLOVER PERIOD clause to end the password rollover (finalizing the password change, so that only the new password can be used).

### Changing a Password During the Gradual Database Password Rollover Period

You can change the password during the password rollover period (before the rollover period expires) using ALTER USER with or without the REPLACE clause.

For example, say user u1 has an original password p1, and p2 is the new password that started the rollover process. Now you want to switch to p3 instead of p2. You can use any one of the statements to change the password to p3:

```
ALTER USER u1 IDENTIFIED BY p3;  
  
ALTER USER u1 IDENTIFIED BY p3 REPLACE p1;  
  
ALTER USER u1 IDENTIFIED BY p3 REPLACE p2;
```

After you change the password to p3, the user can log in using either p1 or p3. Logging in with p2 returns error Invalid credential or not authorized; logon denied and is recorded as a failed login attempt.

The rollover start time remains set to the password change timestamp, this is the time the password of the user was changed. The rollover start time and password change time are not affected by any further password change made during the password rollover period. The old password can be used for at most PASSWORD\_ROLLOVER\_TIME days.

#### See Also:

- Oracle Database Security Guide for guidelines on creating passwords
- Configuring Authentication

#### GLOBALY

Refer to [CREATE USER](#) for more information on this clause.

You can change a user's access verification method *from* IDENTIFIED GLOBALLY to either IDENTIFIED BY *password* or IDENTIFIED EXTERNALLY. You can change a user's access verification method *to* IDENTIFIED GLOBALLY from one of the other methods only if all external roles granted explicitly to the user are revoked.

#### EXTERNALLY

Refer to [CREATE USER](#) for more information on this clause.

#### See Also:

*Oracle Database Enterprise User Security Administrator's Guide* for more information on globally and externally identified users, "[Changing User Identification: Example](#)", and "[Changing User Authentication: Examples](#)"

#### NO AUTHENTICATION Clause

Use this clause to change an existing user account with authentication to a schema account without authentication to prevent logins to the account.

#### DEFAULT COLLATION Clause

Use this clause to change the default collation for the schema owned by the user. The new default collation is assigned to tables, views, and materialized views that are subsequently created in the schema. It does not influence default collations for existing tables views, and materialized views. Refer to the [DEFAULT COLLATION Clause](#) clause of [CREATE USER](#) for the full semantics of this clause.

#### DEFAULT TABLESPACE Clause

Use this clause to assign or reassign a tablespace for the user's permanent segments. This clause overrides any default tablespace that has been specified for the database.

#### Restriction on Default Tablespaces

You cannot specify a locally managed temporary tablespace, including an undo tablespace, or a dictionary-managed temporary tablespace, as a user's default tablespace.

#### [LOCAL] TEMPORARY TABLESPACE Clause

Use this clause to assign or reassign a temporary tablespace or tablespace group for the user's temporary segments.

- Specify *tablespace* to indicate the user's temporary tablespace. Specify TEMPORARY TABLESPACE to indicate a shared temporary tablespace. Specify LOCAL TEMPORARY TABLESPACE to indicate a local temporary tablespace. If you are connected to a CDB, then you can specify CDB\$DEFAULT to use the CDB-wide default temporary tablespace.
- Specify *tablespace\_group\_name* to indicate that the user can save temporary segments in any tablespace in the tablespace group specified by *tablespace\_group\_name*. Local temporary tablespaces cannot be part of a tablespace group.

## Restriction on User Temporary Tablespace

Any individual tablespace you assign or reassign as the user's temporary tablespace must be a temporary tablespace and must have a standard block size.

### See Also:

"[Assigning a Tablespace Group: Example](#)"

## DEFAULT ROLE Clause

Specify the roles enabled by default for the user at logon. This clause can contain only roles that have been granted directly to the user with a `GRANT` statement, or roles created by the user with the `CREATE ROLE` privilege. You cannot use the `DEFAULT ROLE` clause to specify:

- Roles not granted to the user
- Roles granted through other roles
- Roles managed by an external service (such as the operating system), or by the Oracle Internet Directory
- Roles that are enabled by the `SET ROLE` statement, such as password-authenticated roles and secure application roles

### See Also:

[CREATE ROLE](#)

## Assigning Default Roles to Common Users in a CDB

You can modify the default role assigned to a common user both in the current container and across all containers in a CDB.

While assigning a default role to a common user across all containers, `role` must be a common role that was commonly granted to the common user.

While assigning a default role to a common user in the current container, `role` must be one of the following:

- A local role that was granted to the common user in the current container
- A common role that was granted to the common user, either commonly or locally in the current container

## EXPIRE PASSWORD ROLLOVER PERIOD Clause

You can manually expire the password rollover period with `EXPIRE PASSWORD ROLLOVER PERIOD`.

## ENABLE EDITIONS

This clause is not reversible. Specify `ENABLE EDITIONS` to allow the user to create multiple versions of editionable objects in this schema using editions. Editionable objects in non-editions-enabled schemas cannot be editioned.

Use the `FOR` clause to specify one or more object types for which the user can create editionable objects. For a list of valid values for `object_type`, query the `V$EDITIONABLE_TYPES` dynamic performance view.

If you omit the `FOR` clause, then the types that become editionable in the schema are `VIEW`, `SYNONYM`, `PROCEDURE`, `FUNCTION`, `PACKAGE`, `PACKAGE BODY`, `TRIGGER`, `TYPE`, `TYPE BODY`, and `LIBRARY`.

To enable edition for other object types that are not enabled by default, you must explicitly specify the object type in the `FOR` clause.

### Example: Enable Edition for Object Type not Enabled by Default

```
ALTER USER username ENABLE EDITIONS FOR SQL TRANSLATION PROFILE;
```

#### See Also:

- For more on the semantics of the `ENABLE EDITIONS` clause see the corresponding section in [CREATE USER](#)
- Enabling Editions for a User*
- Oracle Database Reference* for more information about the `V$EDITIONABLE_TYPES` dynamic performance view

If the schema to be editions-enabled contains any objects that are not editionable and that depend on editionable type objects in the schema, then you must specify `FORCE` to enable editions for this schema. In this case, all the objects that are not editionable and that depend on the editionable type objects in the schema being editions-enabled become invalid.

## [HTTP] DIGEST Clause

This clause lets you enable or disable HTTP Digest Access Authentication for the user.

- Specify `ENABLE` to enable HTTP Digest Access Authentication. After specifying this clause, you must change the user's password. This causes the database to generate an HTTP Digest verifier for the new password. Only then will HTTP Digest Access Authentication take effect. One way to ensure that the user's password is changed after you issue this clause is to specify the `PASSWORD EXPIRE` clause in the same statement with the `HTTP DIGEST ENABLE` clause, as follows:

```
ALTER USER user PASSWORD EXPIRE HTTP DIGEST ENABLE;
```

This causes the database to prompt the user for a new password on his or her next attempt to log in to the database. After that, HTTP Digest Access Authentication will take effect for the user.

- Specify `DISABLE` to disable HTTP Digest Access Authentication for the user. You do not need to change the user's password in order for this clause to take effect. Specifying the `DISABLE` clause removes the HTTP Digest from dictionary tables.

```
ALTER USER user PASSWORD EXPIRE HTTP DIGEST DISABLE;
```

Refer to [\[HTTP\] DIGEST Clause](#) in the documentation on `CREATE USER` for more information on this clause.

### CONTAINER Clause

If the current container is a PDB, then you can specify `CONTAINER = CURRENT` to change the attributes of a local user, or the container-specific attributes (such as the default tablespace) of a common user, in the current container. If the current container is the root, then you can specify `CONTAINER = ALL` to change the attributes of a common user across the entire CDB. If you omit this clause and the current container is a PDB, then `CONTAINER = CURRENT` is the default. If you omit this clause and the current container is the root, then `CONTAINER = ALL` is the default.

### Restriction on Modifying Common Users in a CDB

Certain attributes of a common user must be modified for all the containers in a CDB and not for only some containers. Therefore, when you use any of the following clauses to modify a common user, ensure that you modify all of the containers by connecting to the root and specifying `CONTAINER=ALL`:

- `IDENTIFIED` clause
- `PASSWORD` clause
- [\[HTTP\] DIGEST](#) clause

### ENABLE or DISABLE DICTIONARY PROTECTION

Use this clause to enable or disable dictionary protection on the created user. When a schema is dictionary protected, other users cannot use system privileges (including `ANY` privileges) on the schema, even if they have been granted the system privilege on the schema. Only the `SELECT ANY DICTIONARY` and `ANALYZE ANY DICTIONARY` system privileges can be used on a dictionary-protected schema. Users can still use object privileges on the schema, assuming that the user has been granted the object privilege on the schema. A user without the object privileges on the object but with corresponding system privileges will be denied access to the object with an insufficient privileges error.

By default, Oracle-maintained schemas have dictionary protection, but this protection can be temporarily removed if necessary. You cannot enable dictionary protection on a customer (Non-Oracle maintained) schema. You also cannot create a custom schema with dictionary protection enabled.

You must be logged in as user `SYS` with the `SYSDBA` administrative privilege in order to manage dictionary protection for Oracle-maintained schemas.

 See Also:

- *Configuring Privilege and Role Authorization of the Oracle Database Security Guide.*

### READ ONLY | READ WRITE

Specify `READ ONLY` to set read-only access to a local PDB user.

With read-only access, the local PDB user is not permitted to execute any write operations on the PDB they connect to. The session operates as if the database is open in read-only mode.

Specify `READ WRITE` to revoke `READ ONLY` access on a local user.

You must have the `ALTER USER` privilege to execute this statement.

You can view the state of a local user in the `*_USERS` view.

### `container_data_clause`

The `container_data_clause` allows you to set and modify `CONTAINER_DATA` attributes for a common user. Use the `FOR` clause to indicate whether to set or modify the default `CONTAINER_DATA` attribute or an object-specific `CONTAINER_DATA` attribute. These attributes determine the set of containers (which can never exclude the root) whose data will be visible via `CONTAINER_DATA` objects to the specified common user when the current session is the root.

To specify the `container_data_clause`, the current session must be the root and you must specify `CONTAINER = CURRENT`.

### `SET CONTAINER_DATA`

Use this clause to set the default `CONTAINER_DATA` attribute or an object-specific `CONTAINER_DATA` attribute for a common user. When you specify this clause, you replace the existing value, if any, of the `CONTAINER_DATA` attribute.

Use `container_name` to specify one or more containers that will be accessible to the user.

Use `ALL` to specify that all current and future containers in the CDB will be accessible to the user.

Use `DEFAULT` to specify the default behavior, which is as follows:

- For a default `CONTAINER_DATA` attribute, the current container, that is, the root, and the CDB as a whole will be accessible to the user.
- For an object-specific `CONTAINER_DATA` attribute, the database will use the user's default `CONTAINER_DATA` attribute.

 **Note:**

CONTAINER\_DATA attributes that are set to DEFAULT are not visible in the DBA\_CONTAINER\_DATA view.

### ADD CONTAINER\_DATA

Use this clause to add containers to the default CONTAINER\_DATA attribute or an object-specific CONTAINER\_DATA attribute for a common user. Use *container\_name* to specify one or more containers to add.

You cannot use this clause if the default CONTAINER\_DATA attribute is set to ALL. If you use this clause when the default CONTAINER\_DATA attribute is set to DEFAULT, then CDB\$ROOT will automatically be added to the set of containers, unless the set already contains CDB\$ROOT.

You cannot use this clause if the object-specific CONTAINER\_DATA attribute is set to ALL or DEFAULT.

### REMOVE CONTAINER\_DATA

Use this clause to remove containers from the default CONTAINER\_DATA attribute or an object-specific CONTAINER\_DATA attribute for a common user. Use *container\_name* to specify one or more containers to remove.

You cannot use this clause if the default CONTAINER\_DATA attribute or object-specific CONTAINER\_DATA attribute is set to ALL or DEFAULT.

### FOR *container\_data\_object*

If you specify the FOR clause, then you can set and modify the object-specific CONTAINER\_DATA attribute for *container\_data\_object* for a common user. *container\_data\_object* must be a CONTAINER\_DATA table or view. If you omit *schema*, then Oracle Database assumes that *container\_data\_object* is in your own schema.

If you omit the FOR clause, then you can set and modify the default CONTAINER\_DATA attribute for a common user.

 **See Also:**

*Oracle Database Security Guide* for more information about enabling common users to view information about PDB objects

### *proxy\_clause*

The *proxy\_clause* lets you control the ability of an enterprise user (a user outside the database) or a database proxy (another database user) to connect as the database user being altered.

### GRANT CONNECT THROUGH

Specify GRANT CONNECT THROUGH to allow the connection.

### REVOKE CONNECT THROUGH

Specify REVOKE CONNECT THROUGH to prohibit the connection.

## ENTERPRISE USER

This clause lets you expose *user* to proxy use by enterprise users. The administrator working in Oracle Internet Directory must then grant privileges for appropriate enterprise users to act on behalf of *user*.

### ***db\_user\_proxy***

This clause lets you expose *user* to proxy use by database user *db\_user\_proxy* (the proxy).

- The proxy will have all privileges that were directly granted to *user*.
- The proxy will have all roles associated with *user*, unless you specify the **WITH** clauses of *db\_user\_proxy\_clauses* to limit the proxy to some or none of the roles of *user*. For each role associated with the proxy, if the role is enabled by default for *user* at login, then that role will also be enabled by default for the proxy at login.

### ***db\_user\_proxy\_clauses***

You can enable password-protected roles in a proxy session. Both secure application role and password-protected roles provide a secure method for enabling a role in a session. Oracle recommends using secure password roles instead of password protected roles in instances where the password has to be maintained and transmitted over insecure channels, or if more than one person needs to know the password.

Password-protected roles in a proxy session are suitable for situations where automation is used to set the role.

Proxy users can access password-protected roles. Specify the **WITH** clauses to limit the proxy to some or none of the roles associated with *user*, and the **AUTHENTICATION REQUIRED** clause to specify whether authentication is required.

### **WITH ROLE**

**WITH ROLE** *role\_name* permits the proxy to connect as the specified user and to activate only the roles that are specified by *role\_name*. This clause can contain only roles that are associated with *user*. Password protected roles and secure application roles also need to be listed in the **WITH ROLE** clause if the Proxy user will need to use these secure roles. These secure roles will be included with the **WITH ROLE ALL** clause (the default if **WITH ROLE** is not specified). If **WITH ROLE** doesn't specify the secure roles, then those cannot be enabled even with right password.

### **WITH ROLE ALL EXCEPT**

**WITH ROLE ALL EXCEPT** *role\_name* permits the proxy to connect as the specified user and to activate all roles associated with that user except those specified for *role\_name*. This clause can contain only roles that are associated with *user*.

### **WITH NO ROLES**

**WITH NO ROLES** permits the proxy to connect as the specified user, but prohibits the proxy from activating any of that user's roles after connecting, even the secure roles like password protected roles and secure application roles.

### **AUTHENTICATION REQUIRED**

Oracle Database does not expect the proxy to authenticate the user unless you specify the AUTHENTICATION REQUIRED clause. This clause ensures that authentication credentials for the user must be presented when the user is authenticated through the specified proxy. The credential is a password.

### AUTHENTICATED USING

The AUTHENTICATED USING clauses, which appeared in the syntax of earlier releases, have been deprecated and are no longer needed. If you specify the AUTHENTICATED USING PASSWORD clause, then Oracle Database converts it to the AUTHENTICATION REQUIRED clause. Specifying the AUTHENTICATED USING CERTIFICATE clause or the AUTHENTICATED USING DISTINGUISHED NAME clause is equivalent to omitting the AUTHENTICATION REQUIRED clause.

#### See Also:

- *Oracle Security Overview* for an overview of database security and for information on middle-tier systems and proxy authentication
- *Oracle Database Security Guide* for more information on proxies and their use of the database and "[Proxy Users: Examples](#)"

## Examples

### Changing User Identification: Example

The following statement changes the password of the user `sidney` (created in "[Creating a Database User: Example](#)") `second_2nd_pwd` and default tablespace to the tablespace `example`:

```
ALTER USER sidney
    IDENTIFIED BY second_2nd_pwd
    DEFAULT TABLESPACE example;
```

The following statement assigns the `new_profile` profile (created in "[Creating a Profile: Example](#)") to the sample user `sh`:

```
ALTER USER sh
    PROFILE new_profile;
```

In subsequent sessions, `sh` is restricted by limits in the `new_profile` profile.

The following statement makes all roles granted directly to `sh` default roles, except the `dw_manager` role:

```
ALTER USER sh
    DEFAULT ROLE ALL EXCEPT dw_manager;
```

At the beginning of `sh`'s next session, Oracle Database enables all roles granted directly to `sh` except the `dw_manager` role.

### Changing User Authentication: Examples

The following statement changes the authentication mechanism of user `app_user1` (created in "[Creating a Database User: Example](#)"):

```
ALTER USER app_user1 IDENTIFIED GLOBALLY AS 'CN=tom,O=oracle,C=US';
```

The following statement causes user `sidney`'s password to expire:

```
ALTER USER sidney PASSWORD EXPIRE;
```

If you cause a database user's password to expire with `PASSWORD EXPIRE`, then the user (or the DBA) must change the password before attempting to log in to the database following the expiration. However, tools such as SQL\*Plus allow the user to change the password on the first attempted login following the expiration.

### Assigning a Tablespace Group: Example

The following statement assigns `tbs_grp_01` (created in "[Adding a Temporary Tablespace to a Tablespace Group: Example](#)") as the tablespace group for user `sh`:

```
ALTER USER sh
  TEMPORARY TABLESPACE tbs_grp_01;
```

### Proxy Users: Examples

The following statement alters the user `app_user1`. The example permits the `app_user1` to connect through the proxy user `sh`. The example also allows `app_user1` to enable its `warehouse_user` role (created in "[Creating a Role: Example](#)") when connected through the proxy `sh`:

```
ALTER USER app_user1
  GRANT CONNECT THROUGH sh
  WITH ROLE warehouse_user;
```

To show basic syntax, this example uses the sample database Sales History user (`sh`) as the proxy. Normally a proxy user would be an application server or middle-tier entity. For information on creating the interface between an application user and a database by way of an application server, refer to *Oracle Call Interface Programmer's Guide*.

#### See Also:

- "[Creating External Database Users: Examples](#)" to see how to create the `app_user` user
- "[Creating a Role: Example](#)" to see how to create the `dw_user` role

The following statement takes away the right of user `app_user1` to connect through the proxy user `sh`:

```
ALTER USER app_user1 REVOKE CONNECT THROUGH sh;
```

The following hypothetical examples shows another method of proxy authentication:

```
ALTER USER sully GRANT CONNECT THROUGH OAS1
  AUTHENTICATED USING PASSWORD;
```

The following example exposes the user `app_user1` to proxy use by enterprise users. The enterprise users cannot act on behalf of `app_user1` until the Oracle Internet Directory administrator has granted them appropriate privileges:

```
ALTER USER app_user1
  GRANT CONNECT THROUGH ENTERPRISE USERS;
```

# ALTER VIEW

## Purpose

Use the `ALTER VIEW` statement to explicitly recompile a view that is invalid or to modify view constraints. Explicit recompilation lets you locate recompilation errors before run time. You may want to recompile a view explicitly after altering one of its base tables to ensure that the alteration does not affect the view or other objects that depend on it.

You can also use `ALTER VIEW` to define, modify, or drop view constraints.

You cannot use this statement to change the definition of an existing view. Further, if DDL changes to the view's base tables invalidate the view, then you cannot use this statement to compile the invalid view. In these cases, you must redefine the view using `CREATE VIEW` with the `OR REPLACE` keywords.

When you issue an `ALTER VIEW` statement, Oracle Database recompiles the view regardless of whether it is valid or invalid. The database also invalidates any local objects that depend on the view.

If you alter a view that is referenced by one or more materialized views, then those materialized views are invalidated. Invalid materialized views cannot be used by query rewrite and cannot be refreshed.

### See Also:

- [CREATE VIEW](#) for information on redefining a view and [ALTER MATERIALIZED VIEW](#) for information on revalidating an invalid materialized view
- *Oracle Database Data Warehousing Guide* for general information on data warehouses
- *Oracle Database Concepts* for more about dependencies among schema objects

## Prerequisites

The view must be in your own schema or you must have `ALTER ANY TABLE` system privilege.

## Syntax

***alter\_view ::=***

(*out\_of\_line\_constraint::=*—part of *constraint::=* syntax), *annotations\_clause*

***annotations\_clause ::=***

For the full syntax and semantics of the *annotations\_clause* see [annotations\\_clause](#).

## Semantics

### IF EXISTS

Specify **IF EXISTS** to alter an existing table.

Specifying **IF NOT EXISTS** with **ALTER VIEW** results in ORA-11544: Incorrect **IF EXISTS** clause for **ALTER/DROP** statement.

### *schema*

Specify the schema containing the view. If you omit *schema*, then Oracle Database assumes the view is in your own schema.

### *view*

Specify the name of the view to be recompiled.

### MODIFY CONSTRAINT Clause

Use the **MODIFY CONSTRAINT** clause to change the **RELY** or **NORELY** setting of an existing view constraint. Refer to "[Notes on View Constraints](#)" for general information on view constraints.

## Restriction on Modifying Constraints

You cannot change the setting of a unique or primary key constraint if it is part of a referential integrity constraint without dropping the foreign key or changing its setting to match that of *view*.

### ADD Clause

Use the ADD clause to add a constraint to *view*. Refer to [constraint](#) for information on view constraints and their restrictions.

### DROP Clause

Use the DROP clause to drop an existing view constraint.

## Restriction on Dropping Constraints

You cannot drop a unique or primary key constraint if it is part of a referential integrity constraint on a view.

### COMPILE

The COMPILE keyword directs Oracle Database to recompile the view.

### { READ ONLY | READ WRITE }

These clauses are valid only for editioning views.

- Specify READ ONLY to indicate that the editioning view cannot be updated.
- Specify READ WRITE to return a read-only editioning view to read/write status.

When you specify these clauses, the database does not invalidate dependent objects, but it may invalidate cursors.

### EDITIONABLE | NONEDITIONABLE

Use these clauses to specify whether the view becomes an editioned or noneditioned object if editioning is later enabled for the schema object type `VIEW` in *schema*. The default is EDITIONABLE. For information about altering editioned and noneditioned objects, see *Oracle Database Development Guide*.

#### See Also:

[CREATE VIEW](#) for information about editioning views

### *annotations\_clause*

For the full semantics of the annotations clause see [annotations\\_clause](#).

You can only change annotations at the view level with the ALTER statement. To drop column-level annotations, you must drop and recreate the view.

### Examples

#### Altering a View: Example

To recompile the view `customer_ro` (created in "Creating a Read-Only View: Example"), issue the following statement:

```
ALTER VIEW customer_ro
    COMPILE;
```

If Oracle Database encounters no compilation errors while recompiling `customer_ro`, then `customer_ro` becomes valid. If recompiling results in compilation errors, then the database returns an error and `customer_ro` remains invalid.

Oracle Database also invalidates all dependent objects. These objects include any procedures, functions, package bodies, and views that reference `customer_ro`. If you subsequently reference one of these objects without first explicitly recompiling it, then the database recompiles it implicitly at run time.

### Add and Drop Annotations: Example

The following example drops annotation `Title` from view `MView1` and adds annotation `Identity`:

```
ALTER VIEW HighWageEmp ANNOTATIONS (DROP Title, ADD Identity);
```

## ANALYZE

### Purpose

Use the `ANALYZE` statement to collect statistics, for example, to:

- Collect or delete statistics about an index or index partition, table or table partition, index-organized table, cluster, or scalar object attribute.
- Validate the structure of an index or index partition, table or table partition, index-organized table, cluster, or object reference (`REF`).
- Identify migrated and chained rows of a table or cluster.

#### Note:

The use of `ANALYZE` for the collection of optimizer statistics is obsolete.

If you want to collect optimizer statistics, use the `DBMS_STATS` package, which lets you collect statistics in parallel, global statistics for partitioned objects, and helps you fine tune your statistics collection in other ways. See *Oracle Database PL/SQL Packages and Types Reference* for more information on the `DBMS_STATS` package.

Use the `ANALYZE` statement only for the following cases:

- To use the `VALIDATE` or `LIST CHAINED ROWS` clauses
- To collect information on freelist blocks

### Prerequisites

The schema object to be analyzed must be local, and it must be in your own schema or you must have the `ANALYZE ANY` system privilege.

If you want to list chained rows of a table or cluster into a list table, then the list table must be in your own schema, or you must have `INSERT` privilege on the list table, or you must have `INSERT ANY TABLE` system privilege.

If you want to validate a partitioned table, then you must have the `INSERT` object privilege on the table into which you list analyzed rowids, or you must have the `INSERT ANY TABLE` system privilege.

### Syntax

**analyze::=**

**partition\_extension\_clause::=**

**validation\_clauses::=**

*into\_clause ::=*

### Semantics

#### *schema*

Specify the schema containing the table, index, or cluster. If you omit *schema*, then Oracle Database assumes the table, index, or cluster is in your own schema.

#### **TABLE *table***

Specify a table to be analyzed. When you analyze a table, the database collects statistics about expressions occurring in any function-based indexes as well. Therefore, be sure to create function-based indexes on the table before analyzing the table. Refer to [CREATE INDEX](#) for more information about function-based indexes.

When analyzing a table, the database skips all domain indexes marked `LOADING` or `FAILED`.

For an index-organized table, the database also analyzes any mapping table and calculates its `PCT_ACCESSS_DIRECT` statistics. These statistics estimate the accuracy of guess data block addresses stored as part of the local rowids in the mapping table.

Oracle Database collects the following statistics for a table. Statistics marked with an asterisk are always computed exactly. Table statistics, including the status of domain indexes, appear in the data dictionary views `USER_TABLES`, `ALL_TABLES`, and `DBA_TABLES` in the columns shown in parentheses.

- Number of rows (`NUM_ROWS`)
- \* Number of data blocks below the high water mark—the number of data blocks that have been formatted to receive data, regardless whether they currently contain data or are empty (`BLOCKS`)
- \* Number of data blocks allocated to the table that have never been used (`EMPTY_BLOCKS`)
- Average available free space in each data block in bytes (`AVG_SPACE`)
- Number of chained rows (`CHAIN_COUNT`)
- Average row length, including the row overhead, in bytes (`AVG_ROW_LEN`)

### Restrictions on Analyzing Tables

Analyzing tables is subject to the following restrictions:

- You cannot use `ANALYZE` to collect statistics on data dictionary tables.
- You cannot use `ANALYZE` to collect statistics on an external table. Instead, you must use the `DBMS_STATS` package.
- You cannot use `ANALYZE` to collect default statistics on a temporary table. However, if you have already created an association between one or more columns of a

temporary table and a user-defined statistics type, then you can use `ANALYZE` to collect the user-defined statistics on the temporary table.

- You cannot compute or estimate statistics for the following column types: `REF` column types, varrays, nested tables, LOB column types (LOB column types are not analyzed, they are skipped), `LONG` column types, or object types. However, if a statistics type is associated with such a column, then Oracle Database collects user-defined statistics.

 **See Also:**

- [ASSOCIATE STATISTICS](#)
- *Oracle Database Reference* for information on the data dictionary views

***partition\_extension\_clause***

***partition\_extension\_clause***

Specify the partition or subpartition, or the partition or subpartition value, on which you want statistics to be gathered. You cannot use this clause when analyzing clusters.

If you specify `PARTITION` and `table` is composite-partitioned, then Oracle Database analyzes all the subpartitions within the specified partition.

**INDEX *index***

Specify an index to be analyzed.

Oracle Database collects the following statistics for an index. Statistics marked with an asterisk are always computed exactly. For conventional indexes, when you compute or estimate statistics, the statistics appear in the data dictionary views `USER_INDEXES`, `ALL_INDEXES`, and `DBA_INDEXES` in the columns shown in parentheses.

- \* Depth of the index from its root block to its leaf blocks (`BLEVEL`)
- Number of leaf blocks (`LEAF_BLOCKS`)
- Number of distinct index values (`DISTINCT_KEYS`)
- Average number of leaf blocks for each index value (`AVG_LEAF_BLOCKS_PER_KEY`)
- Average number of data blocks for each index value (for an index on a table) (`AVG_DATA_BLOCKS_PER_KEY`)
- Clustering factor (how well ordered the rows are about the indexed values) (`CLUSTERING_FACTOR`)

For domain indexes, this statement invokes the user-defined statistics collection function specified in the statistics type associated with the index (see [ASSOCIATE STATISTICS](#)). If no statistics type is associated with the domain index, then the statistics type associated with its `indxtype` is used. If no statistics type exists for either the index or its `indxtype`, then no user-defined statistics are collected. User-defined index statistics appear in the `STATISTICS` column of the data dictionary views `USER_USTATS`, `ALL_USTATS`, and `DBA_USTATS`.

 **Note:**

- When you analyze an index from which a substantial number of rows has been deleted, Oracle Database sometimes executes a `COMPUTE` statistics operation (which can entail a full table scan) even if you request an `ESTIMATE` statistics operation. Such an operation can be quite time consuming.
- In some cases, analyzing an index with the `ANALYZE` statement takes an inordinate amount of time to complete. In these cases, you can use a SQL query to validate the index. If the query determines that there is an inconsistency between a table and the index, then you can use the `ANALYZE` statement for a thorough analysis of the index. Refer to *Oracle Database Administrator's Guide* for more information.

### Restriction on Analyzing Indexes

You cannot analyze a domain index that is marked `IN_PROGRESS` or `FAILED`.

 **See Also:**

- [CREATE INDEX](#) for more information on domain indexes
- [Oracle Database Reference](#) for information on the data dictionary views
- ["Analyzing an Index: Example"](#)

### CLUSTER *cluster*

Specify a cluster to be analyzed. When you collect statistics for a cluster, Oracle Database also automatically collects the statistics for all the tables in the cluster and all their indexes, including the cluster index.

For both indexed and hash clusters, the database collects the average number of data blocks taken up by a single cluster key (`AVG_BLOCKS_PER_KEY`). These statistics appear in the data dictionary views `ALL_CLUSTERS`, `USER_CLUSTERS`, and `DBA_CLUSTERS`.

 **See Also:**

[Oracle Database Reference](#) for information on the data dictionary views and ["Analyzing a Cluster: Example"](#)

### *validation\_clauses*

The validation clauses let you validate `REF` values and the structure of the analyzed object.

 **See Also:**

*Oracle Database Administrator's Guide* for more information about validating tables, indexes, clusters, and materialized views

### VALIDATE REF UPDATE Clause

Specify `VALIDATE REF UPDATE` to validate the `REF` values in the specified table, check the `rowid` portion in each `REF`, compare it with the true `rowid`, and correct it, if necessary. You can use this clause only when analyzing a table.

If the owner of the table does not have the `READ` or `SELECT` object privilege on the referenced objects, then Oracle Database will consider them invalid and set them to null. Subsequently these `REF` values will not be available in a query, even if it is issued by a user with appropriate privileges on the objects.

### SET DANGLING TO NULL

`SET DANGLING TO NULL` sets to null any `REF` values (whether or not scoped) in the specified table that are found to point to an invalid or nonexistent object.

### VALIDATE STRUCTURE

Specify `VALIDATE STRUCTURE` to validate the structure of the analyzed object. The statistics collected by this clause are not used by the Oracle Database optimizer.

 **See Also:**

"[Validating a Table: Example](#)"

- For a table, Oracle Database verifies the integrity of each of the data blocks and rows. For an index-organized table, the database also generates compression statistics (optimal prefix compression count) for the primary key index on the table.
- For a cluster, Oracle Database automatically validates the structure of the cluster tables.
- For a partitioned table, Oracle Database also verifies that each row belongs to the correct partition. If a row does not collate correctly, then its `rowid` is inserted into the `INVALID_ROWS` table.
- For a temporary table, Oracle Database validates the structure of the table and its indexes during the current session.
- For an index, Oracle Database verifies the integrity of each data block in the index and checks for block corruption. This clause does not confirm that each row in the table has an index entry or that each index entry points to a row in the table. You can perform these operations by validating the structure of the table with the `CASCADE` clause.

Oracle Database also computes compression statistics (optimal prefix compression count) for all normal indexes.

Oracle Database stores statistics about the index in the data dictionary views `INDEX_STATS` and `INDEX_HISTOGRAM`.

 **See Also:**

*Oracle Database Reference* for information on these views

If Oracle Database encounters corruption in the structure of the object, then an error message is returned. In this case, drop and re-create the object.

**CASCADE**

Specify **CASCADE** if you want Oracle Database to validate the structure of the indexes associated with the table or cluster. If you use this clause when validating a table, then the database also validates the indexes defined on the table. If you use this clause when validating a cluster, then the database also validates all the cluster tables indexes, including the cluster index.

By default, **CASCADE** performs a **COMPLETE** validation, which can be resource intensive. Specify **FAST** if you want the database to check for the existence of corruptions without reporting details about the corruption. If the **FAST** check finds a corruption, you can then use the **CASCADE** option without the **FAST** clause to locate and learn details about it.

If you use this clause to validate an enabled (but previously disabled) function-based index, then validation errors may result. In this case, you must rebuild the index.

**ONLINE | OFFLINE**

Specify **ONLINE** to enable Oracle Database to run the validation while DML operations are ongoing within the object. The database reduces the amount of validation performed to allow for concurrency.

 **Note:**

When you validate the structure of an object **ONLINE**, Oracle Database does not collect any statistics, as it does when you validate the structure of the object **OFFLINE**.

Specify **OFFLINE**, to maximize the amount of validation performed. This setting prevents **INSERT**, **UPDATE**, and **DELETE** statements from concurrently accessing the object during validation but allows queries. This is the default.

**Restriction on ONLINE**

You cannot specify **ONLINE** when analyzing a cluster.

**INTO**

The **INTO** clause of **VALIDATE STRUCTURE** is valid only for partitioned tables. Specify a table into which Oracle Database lists the rowids of the partitions whose rows do not collate correctly. If you omit *schema*, then the database assumes the list is in your own schema. If you omit this clause altogether, then the database assumes that the table is named **INVALID\_ROWS**. The SQL script used to create this table is **UTLVALID.SQL**.

## LIST CHAINED ROWS

LIST CHAINED ROWS lets you identify migrated and chained rows of the analyzed table or cluster. You cannot use this clause when analyzing an index.

In the `INTO` clause, specify a table into which Oracle Database lists the migrated and chained rows. If you omit `schema`, then the database assumes the chained-rows table is in your own schema. If you omit this clause altogether, then the database assumes that the table is named `CHAINED_ROWS`. The chained-rows table must be on your local database.

You can create the `CHAINED_ROWS` table using one of these scripts:

- `UTLCHAIN.SQL` uses physical rowids. Therefore it can accommodate rows from conventional tables but not from index-organized tables. (See the Note that follows.)
- `UTLCHN1.SQL` uses universal rowids, so it can accommodate rows from both conventional and index-organized tables.

If you create your own chained-rows table, then it must follow the format prescribed by one of these two scripts.

If you are analyzing index-organized tables based on primary keys (rather than universal rowids), then you must create a separate chained-rows table for each index-organized table to accommodate its primary-key storage. Use the SQL scripts `DBMSIOTC.SQL` and `PRVTIOTC.PLB` to define the `BUILD_CHAIN_ROWS_TABLE` procedure, and then execute this procedure to create an `IOT_CHAINED_ROWS` table for each such index-organized table.

### See Also:

- The `DBMS_IOT` package in *Oracle Database PL/SQL Packages and Types Reference* for information on the packaged SQL scripts
- "[Listing Chained Rows: Example](#)"

## DELETE STATISTICS

Specify `DELETE STATISTICS` to delete any statistics about the analyzed object that are currently stored in the data dictionary. Use this statement when you no longer want Oracle Database to use the statistics.

When you use this clause on a table, the database also automatically removes statistics for all the indexes defined on the table. When you use this clause on a cluster, the database also automatically removes statistics for all the cluster tables and all their indexes, including the cluster index.

Specify `SYSTEM` if you want Oracle Database to delete only system (not user-defined) statistics. If you omit `SYSTEM`, and if user-defined column or index statistics were collected for an object, then the database also removes the user-defined statistics by invoking the statistics deletion function specified in the statistics type that was used to collect the statistics.

 See Also:

"[Deleting Statistics: Example](#)"

## Examples

### Deleting Statistics: Example

The following statement deletes statistics about the sample table `oe.orders` and all its indexes from the data dictionary:

```
ANALYZE TABLE orders DELETE STATISTICS;
```

### Analyzing an Index: Example

The following statement validates the structure of the sample index `oe.inv_product_ix`:

```
ANALYZE INDEX inv_product_ix VALIDATE STRUCTURE;
```

### Validating a Table: Example

The following statement analyzes the sample table `hr.employees` and all of its indexes:

```
ANALYZE TABLE employees VALIDATE STRUCTURE CASCADE;
```

For a table, the `VALIDATE REF UPDATE` clause verifies the `REF` values in the specified table, checks the `rowid` portion of each `REF`, and then compares it with the true `rowid`. If the result is an incorrect `rowid`, then the `REF` is updated so that the `rowid` portion is correct.

The following statement validates the `REF` values in the sample table `oe.customers`:

```
ANALYZE TABLE customers VALIDATE REF UPDATE;
```

The following statement validates the structure of the sample table `oe.customers` while allowing simultaneous DML:

```
ANALYZE TABLE customers VALIDATE STRUCTURE ONLINE;
```

### Analyzing a Cluster: Example

The following statement analyzes the `personnel` cluster (created in "[Creating a Cluster: Example](#)"), all of its tables, and all of their indexes, including the cluster index:

```
ANALYZE CLUSTER personnel
    VALIDATE STRUCTURE CASCADE;
```

### Listing Chained Rows: Example

The following statement collects information about all the chained rows in the table `orders`:

```
ANALYZE TABLE orders
    LIST CHAINED ROWS INTO chained_rows;
```

The preceding statement places the information into the table `chained_rows`. You can then examine the rows with this query (no rows will be returned if the table contains no chained rows):

```
SELECT owner_name, table_name, head_rowid, analyze_timestamp
      FROM chained_rows
     ORDER BY owner_name, table_name, head_rowid, analyze_timestamp;

OWNER_NAME  TABLE_NAME   HEAD_ROWID          ANALYZE_TIMESTAMP
-----  -----  -----
OE          ORDERS      AAAAZzAABAAABrXAAA  25-SEP-2000
```

## ASSOCIATE STATISTICS

### Purpose

Use the `ASSOCIATE STATISTICS` statement to associate a statistics type (or default statistics) containing functions relevant to statistics collection, selectivity, or cost with one or more columns, standalone functions, packages, types, domain indexes, or indextypes.

For a listing of all current statistics type associations, query the `USER_ASSOCIATIONS` data dictionary view. If you analyze the object with which you are associating statistics, then you can also query the associations in the `USER_USTATS` view.

 **See Also:**

[ANALYZE](#) for information on the order of precedence with which `ANALYZE` uses associations

### Prerequisites

To issue this statement, you must have the appropriate privileges to alter the base object (table, function, package, type, domain index, or indextype). In addition, unless you are associating only default statistics, you must have execute privilege on the statistics type. The statistics type must already have been defined.

 **See Also:**

[CREATE TYPE](#) for information on defining types

### Syntax

`associate_statistics ::=`

*column\_association ::=*

*function\_association ::=*

*using\_statistics\_type ::=*

*default\_cost\_clause ::=*

**default\_selectivity\_clause ::=**

**storage\_table\_clause ::=**

### Semantics

#### *column\_association*

Specify one or more table columns. If you do not specify *schema*, then Oracle Database assumes the table is in your own schema.

#### *function\_association*

Specify one or more standalone functions, packages, user-defined data types, domain indexes, or indextypes. If you do not specify *schema*, then Oracle Database assumes the object is in your own schema.

- FUNCTIONS refers only to standalone functions, not to method types or to built-in functions.
- TYPES refers only to user-defined types, not to built-in SQL data types.

#### Restriction on *function\_association*

You cannot specify an object for which you have already defined an association. You must first disassociate the statistics from this object.

#### See Also:

[DISASSOCIATE STATISTICS "Associating Statistics: Example"](#)

#### *using\_statistics\_type*

Specify the statistics type (or a synonym for the type) being associated with column, function, package, type, domain index, or indextype. The *statistics\_type* must already have been created.

The `NULL` keyword is valid only when you are associating statistics with a column or an index. When you associate a statistics type with an object type, columns of that object type inherit the statistics type. Likewise, when you associate a statistics type with an indextype, index instances of the indextype inherit the statistics type. You can override this inheritance by associating a different statistics type for the column or index. Alternatively, if you do not want

to associate any statistics type for the column or index, then you can specify `NULL` in the `using_statistics_type` clause.

### Restriction on Specifying Statistics Type

You cannot specify `NULL` for functions, packages, types, or indextypes.

#### See Also:

*Oracle Database Data Cartridge Developer's Guide* for information on creating statistics collection functions

### `default_cost_clause`

Specify default costs for standalone functions, packages, types, domain indexes, or indextypes. If you specify this clause, then you must include one number each for CPU cost, I/O cost, and network cost, in that order. Each cost is for a single execution of the function or method or for a single domain index access. Accepted values are integers of zero or greater.

### `default_selectivity_clause`

Specify as a percent the default selectivity for predicates with standalone functions, types, packages, or user-defined operators. The `default_selectivity_clause` must be a number between 0 and 100. Values outside this range are ignored.

### Restriction on the `default_selectivity_clause`

You cannot specify `DEFAULT SELECTIVITY` for domain indexes or indextypes.

#### See Also:

["Specifying Default Cost: Example"](#)

### `storage_table_clause`

This clause is relevant only for statistics on `INDEXTYPE`.

- Specify `WITH SYSTEM MANAGED STORAGE TABLES` to indicate that the storage of statistics data is to be managed by the system. The type you specify in `statistics_type` should be storing the statistics related information in tables that are maintained by the system. Also, the indextype you specify must already have been created or altered to support the `WITH SYSTEM MANAGED STORAGE TABLES` clause.
- Specify `WITH USER MANAGED STORAGE TABLES` to indicate that the tables that store the user-defined statistics will be managed by the user. This is the default behavior.

### Examples

#### **Associating Statistics: Example**

This statement creates an association for the standalone package `emp_mgmt`. See *Oracle Database PL/SQL Language Reference* for the example that creates this package.

```
ASSOCIATE STATISTICS WITH PACKAGES emp_mgmt DEFAULT SELECTIVITY 10;
```

#### Specifying Default Cost: Example

This statement specifies that using the domain index `salary_index`, created in "Using Extensible Indexing", to implement a given predicate always has a CPU cost of 100, I/O cost of 5, and network cost of 0.

```
ASSOCIATE STATISTICS WITH INDEXES salary_index DEFAULT COST (100,5,0);
```

The optimizer will use these default costs instead of calling a cost function.

## AUDIT (Traditional Auditing)

### Note:

Traditional Auditing is unsupported in Oracle Database 23c. Unified Auditing replaces traditional auditing in this version.

## AUDIT (Unified Auditing)

This section describes the `AUDIT` statement for **unified auditing**. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to *Oracle Database Security Guide* for more information on unified auditing.

### Purpose

Use the `AUDIT` statement to:

- Enable a unified audit policy for all users or for specified users
- Specify whether an audit record is created if the audited event fails, succeeds, or both
- Specify application context attributes, whose values will be recorded in audit records

Changes made to the audit policy become effective immediately in the current session and in all active sessions without re-login.

### See Also:

- [NOAUDIT \(Unified Auditing\)](#)
- [CREATE AUDIT POLICY \(Unified Auditing\)](#)
- [ALTER AUDIT POLICY \(Unified Auditing\)](#)
- [DROP AUDIT POLICY \(Unified Auditing\)](#)

## Prerequisites

You must have the AUDIT SYSTEM system privilege or the AUDIT\_ADMIN role.

If you are connected to a multitenant container database (CDB), then to enable a common unified audit policy, the current container must be the root and you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT\_ADMIN common role. To enable a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT\_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT\_ADMIN local role in the container.

To specify the AUDIT CONTEXT ... statement when connected to a CDB, you must have the commonly granted AUDIT SYSTEM privilege or the AUDIT\_ADMIN common role, or you must have the locally granted AUDIT SYSTEM privilege or the AUDIT\_ADMIN local role in the current session's container.

## Syntax

*unified\_audit ::=*

*by\_users\_with\_roles ::=*

## Semantics

*policy*

With Oracle Database Release 21c unified audit policies are enforced on the current user who executes the SQL statement.

Specify the name of the unified audit policy to be enabled. (The policy must be created previously by the CREATE AUDIT POLICY statement.) The policy becomes active immediately for the current session and active ongoing sessions as soon as the AUDIT POLICY statement is executed.

You can find descriptions of all unified audit policies by querying the AUDIT\_UNIFIED\_POLICIES view and descriptions of all *enabled* unified audit policies by querying the AUDIT\_UNIFIED\_ENABLED\_POLICIES view.

When you enable a unified audit policy, all SQL statements and operations that satisfy either a system privilege or action or role audit option specified in the enabled policy will be audited—that is, a unified audit record will be created in the UNIFIED\_AUDIT\_TRAIL view. If a single SQL statement or operation satisfies multiple enabled policies, then only one unified audit record will be created and all satisfied audit policy names will appear in a comma-separated list in the UNIFIED\_AUDIT\_POLICIES column of the UNIFIED\_AUDIT\_TRAIL view.

#### See Also:

- [CREATE AUDIT POLICY \(Unified Auditing\)](#)
- [Oracle Database Reference](#) for more information on the AUDIT\_UNIFIED\_POLICIES, AUDIT\_UNIFIED\_ENABLED\_POLICIES, and UNIFIED\_AUDIT\_TRAIL views

## BY | EXCEPT

Specify the BY clause to enable *policy* for only the specified users.

Specify the EXCEPT clause to enable *policy* for all users except the specified users.

If you omit the BY and EXCEPT clauses and the *by\_users\_with\_roles* clause, then Oracle Database enables *policy* for all users.

If *policy* is a common unified audit policy, then *user* must be a common user. If *policy* is a local unified audit policy, then *user* must be a common user or a local user in the container to which you are connected.

### Notes on the BY and EXCEPT Clauses

The following notes apply to the BY and EXCEPT clauses:

- If multiple AUDIT ... BY ... statements are specified for the same unified audit policy, then the policy is enabled for the union of the users specified in each statement.
- If multiple AUDIT ... EXCEPT ... statements are specified for the same unified audit policy, then only the most recently specified statement takes effect. That is, the policy is enabled for all users except the users specified in the most recent AUDIT ... EXCEPT ... statement.
- If a policy is enabled using the BY clause and you would like to instead enable it using the EXCEPT clause, then you must first use the NOAUDIT ... BY ... statement to disable the policy for all users for whom the policy is currently enabled, and then enable the policy with the AUDIT ... EXCEPT ... statement.
- If a policy is enabled using the EXCEPT clause and you would like to instead enable it using the BY clause, then you must first use the NOAUDIT statement to disable the audit policy. Note that you cannot specify the EXCEPT clause with the NOAUDIT statement. You can then enable the policy with the AUDIT ... BY ... statement.

### Restriction on the BY and EXCEPT Clauses

You cannot specify an AUDIT ... BY ... statement and an AUDIT ... EXCEPT ... statement for the same unified audit policy. If you attempt to do so, then an error occurs.

#### ***by\_users\_with\_roles***

Specify this clause to enable *policy* for users who have been directly or indirectly granted the specified roles. If you subsequently grant one of the roles to an additional user or to a role which is directly or indirectly granted to a user, then the policy automatically applies to that user. If you subsequently revoke one of the roles from a user or from a role which was directly or indirectly granted to a role or a user, then the policy no longer applies to that user.

When you are connected to a CDB, if *policy* is a common unified audit policy, then *role* must be a common role. If *policy* is a local unified audit policy, then *role* must be a common role or a local role in the container to which you are connected.

#### **Enabling a Local Audit Policy on Roles**

Local audit policy can be enabled on local roles as well as on common roles. When a local audit policy is enabled on a common role, it generates audit records when a common role is granted to user locally or commonly in the container.

#### **Enabling a Common Audit Policy on Roles**

Common audit policy can only be enabled on common roles. When a common audit policy is enabled on a common role, it generates audit records when a common role is granted to an user commonly or locally in the ROOT container.

#### **WHENEVER [NOT] SUCCESSFUL**

Specify WHENEVER SUCCESSFUL to audit only SQL statements and operations that succeed.

Specify WHENEVER NOT SUCCESSFUL to audit only SQL statements and operations that fail or result in errors.

If you omit this clause, then Oracle Database performs the audit regardless of success or failure.

#### **CONTEXT Clause**

Specify the CONTEXT clause to include the values of context attributes in audit records.

- For *namespace*, specify the context namespace.
- For *attribute*, specify one or more context attributes whose values you want to include in audit records.
- Use the optional BY *user* clause to include the values of the context attributes only in audit records for events executed by the specified users. If you omit the BY clause, then the values of the context attributes are included in all audit records.

If you specify the CONTEXT clause when the current container is the root of a CDB, then the values of context attributes will be included in audit records only for events executed in the root. If you specify the optional BY clause, then *user* must be a common user.

If you specify the CONTEXT clause when the current container is a pluggable database (PDB), then the values of context attributes will be included in audit records only for

events executed in that PDB. If you specify the optional `BY` clause, then `user` must be a common user or a local user in that PDB.

You can find the application context attributes that are configured to be captured in the audit trail by querying the `AUDIT_UNIFIED_CONTEXTS` view.

### See Also:

*Oracle Database Reference* for more information on the `AUDIT_UNIFIED_CONTEXTS` view

## Examples

The following examples enable unified audit policies that were created in the `CREATE AUDIT POLICY "Examples"`.

### Enabling a Unified Audit Policy for All Users: Example

The following statement enables unified audit policy `table_pol` for all users:

```
AUDIT POLICY table_pol;
```

The following statement verifies that `table_pol` is enabled for all users:

```
SELECT policy_name, enabled_option, entity_name
  FROM audit_unified_enabled_policies
 WHERE policy_name = 'TABLE_POL';

POLICY_NAME  ENABLED_OPTION  ENTITY_NAME
-----  -----  -----
TABLE_POL    BY             ALL USERS
```

### Enabling a Unified Audit Policy for Specific Users: Examples

The following statement enables unified audit policy `dml_pol` for only users `hr` and `sh`:

```
AUDIT POLICY dml_pol BY hr, sh;
```

The following statement verifies that `dml_pol` is enabled for only users `hr` and `sh`:

```
SELECT policy_name, enabled_option, entity_name
  FROM audit_unified_enabled_policies
 WHERE policy_name = 'DML_POL'
 ORDER BY user_name;

POLICY_NAME  ENABLED_OPTION  ENTITY_NAME
-----  -----  -----
DML_POL     BY             HR
DML_POL     BY             SH
```

The following statement enables unified audit policy `read_dir_pol` for all users except `hr`:

```
AUDIT POLICY read_dir_pol EXCEPT hr;
```

The following statement verifies that `read_dir_pol` is enabled for all users except `hr`:

```
SELECT policy_name, enabled_option, entity_name
  FROM audit_unified_enabled_policies
```

```
WHERE policy_name = 'READ_DIR_POL';

POLICY_NAME    ENABLED_OPTION   ENTITY_NAME
-----  -----  -----
READ_DIR_POL    EXCEPT        HR
```

The following statement enables unified audit policy `security_pol` for user `hr` and audits only the SQL statements and operations that fail:

```
AUDIT POLICY security_pol BY hr WHENEVER NOT SUCCESSFUL;
```

The following statement verifies that `security_pol` is enabled for only user `hr` and that only the SQL statements and operations that fail will be audited:

```
SELECT policy_name, enabled_option, entity_name, success, failure
  FROM audit_unified_enabled_policies
 WHERE policy_name = 'SECURITY_POL';
```

POLICY_NAME	ENABLED_OPTION	ENTITY_NAME	SUCCESS	FAILURE
SECURITY_POL	BY	HR	NO	YES

### Including Values of Context Attributes in Audit Records: Example

The following statement instructs the database to include the values of namespace `USERENV` attributes `CURRENT_USER` and `DB_NAME` in all audit records for user `hr`:

```
AUDIT CONTEXT NAMESPACE userenv
  ATTRIBUTES current_user, db_name
  BY hr;
```

## CALL

### Purpose

Use the `CALL` statement to execute a **routine** (a standalone procedure or function, or a procedure or function defined within a type or package) from within SQL.

#### Note:

The restrictions on user-defined function expressions specified in "Function Expressions" apply to the `CALL` statement as well.

#### See Also:

*Oracle Database PL/SQL Language Reference* for information on creating such routine

### Prerequisites

You must have `EXECUTE` privilege on the standalone routine or on the type or package in which the routine is defined.

## Syntax

**call ::=**

**routine\_clause ::=**

**object\_access\_expression ::=**

## Semantics

You can execute a routine in two ways. You can issue a call to the routine itself by name, by using the `routine_clause`, or you can invoke a routine inside the type of an expression, by using an `object_access_expression`.

**routine\_clause**

Specify the name of the function or procedure being called, or a synonym that resolves to a function or procedure.

When you call a member function or procedure of a type, if the first argument (`SELF`) is a null `IN OUT` argument, then Oracle Database returns an error. If `SELF` is a null `IN` argument, then the database returns null. In both cases, the function or procedure is not invoked.

### Restriction on Functions

If the routine is a function, then the `INTO` clause is required.

#### ***schema***

Specify the schema in which the standalone routine, or the package or type containing the routine, resides. If you do not specify `schema`, then Oracle Database assumes the routine is in your own schema.

#### ***type or package***

Specify the type or package in which the routine is defined.

#### ***@dblink***

In a distributed database system, specify the name of the database containing the standalone routine, or the package or function containing the routine. If you omit `dblink`, then Oracle Database looks in your local database.

#### See Also:

"[Calling a Procedure: Example](#)" for an example of calling a routine directly

#### ***object\_access\_expression***

If you have an expression of an object type, such as a type constructor or a bind variable, then you can use this form of expression to call a routine defined within the type. In this context, the `object_access_expression` is limited to method invocations.

#### See Also:

"[Object Access Expressions](#)" for syntax and semantics of this form of expression, and "[Calling a Procedure Using an Expression of an Object Type: Example](#)" for an example of calling a routine using an expression of an object type

#### ***argument***

Specify one or more arguments to the routine, if the routine takes arguments. You can use positional, named, or mixed notation for `argument`. For example, all of the following notations are correct:

```
CALL my_procedure(arg1 => 3, arg2 => 4)
```

```
CALL my_procedure(3, 4)
```

```
CALL my_procedure(3, arg2 => 4)
```

## Restrictions on Applying Arguments to Routines

The *argument* is subject to the following restrictions:

- The data types of the parameters passed by the `CALL` statement must be SQL data types. They cannot be PL/SQL-only data types such as `BOOLEAN`.
- An *argument* cannot be a pseudocolumn or either of the object reference functions `VALUE` or `REF`.
- Any *argument* that is an `IN OUT` or `OUT` argument of the routine must correspond to a host variable expression.
- The number of arguments, including any return argument, is limited to 1000.
- You cannot bind arguments of character and raw data types (`CHAR`, `VARCHAR2`, `NCHAR`, `NVARCHAR2`, `RAW`, `LONG RAW`) that are larger than 4K.

### `INTO :host_variable`

The `INTO` clause applies only to calls to functions. Specify which host variable will store the return value of the function.

### `:indicator_variable`

Specify the value or condition of the host variable.

#### See Also:

*Pro\*C/C++ Programmer's Guide* for more information on host variables and indicator variables

## Examples

### Calling a Procedure: Example

The following statement removes the Entertainment department (created in "[Inserting Sequence Values: Example](#)") using uses the `remove_dept` procedure. See *Oracle Database PL/SQL Language Reference* for the example that creates this procedure.

```
CALL emp_mgmt.remove_dept(162);
```

### Calling a Procedure Using an Expression of an Object Type: Example

The following examples show how call a procedure by using an expression of an object type in the `CALL` statement. The example uses the `warehouse_typ` object type in the order entry sample schema OE:

```
ALTER TYPE warehouse_typ
    ADD MEMBER FUNCTION ret_name
    RETURN VARCHAR2
    CASCADE;

CREATE OR REPLACE TYPE BODY warehouse_typ
    AS MEMBER FUNCTION ret_name
    RETURN VARCHAR2
    IS
        BEGIN
```

```
        RETURN self.warehouse_name;
    END;
END;
/
VARIABLE x VARCHAR2(25);

CALL warehouse_typ(456, 'Warehouse 456', 2236).ret_name()
  INTO :x;

PRINT x;
X
-----
Warehouse 456
```

The next example shows how to use an external function to achieve the same thing:

```
CREATE OR REPLACE FUNCTION ret_warehouse_typ(x warehouse_typ)
  RETURN warehouse_typ
  IS
    BEGIN
      RETURN x;
    END;
/
CALL ret_warehouse_typ(warehouse_typ(234, 'Warehouse 234',
  2235)).ret_name()
  INTO :x;

PRINT x;
X
-----
Warehouse 234
```

## COMMENT

### Purpose

Use the `COMMENT` statement to add to the data dictionary a comment about a table or table column, unified audit policy, edition, indextype, materialized view, mining model, operator, or view.

To drop a comment from the database, set it to the empty string ''.

#### See Also:

- "[Comments](#)" for more information on associating comments with SQL statements and schema objects
- *Oracle Database Reference* for information on the data dictionary views that display comments

### Prerequisites

The object about which you are adding a comment must be in your own schema or:

- To add a comment to a table, view, or materialized view, you must have COMMENT ANY TABLE system privilege.
- To add a comment to a unified audit policy, you must have the AUDIT SYSTEM system privilege or the AUDIT\_ADMIN role.
- To add a comment to an edition, you must have the CREATE ANY EDITION system privilege, granted either directly or through a role.
- To add a comment to an indextype, you must have the CREATE ANY INDEXTYPE system privilege.
- To add a comment to a mining model, you must have the COMMENT ANY MINING MODEL system privilege.
- To add a comment to an operator, you must have the CREATE ANY OPERATOR system privilege.

## Syntax

*comment ::=*

## Semantics

### AUDIT POLICY Clause

Specify the name of the unified audit policy to be commented.

You can view the comments on a particular unified audit policy by querying the AUDIT\_UNIFIED\_POLICY\_COMMENTS data dictionary view.

### COLUMN Clause

Specify the name of the column of a table, view, or materialized view to be commented. If you omit *schema*, then Oracle Database assumes the table, view, or materialized view is in your own schema.

You can view the comments on a particular table or column by querying the data dictionary views `USER_TAB_COMMENTS`, `DBA_TAB_COMMENTS`, or `ALL_TAB_COMMENTS` or `USER_COL_COMMENTS`, `DBA_COL_COMMENTS`, or `ALL_COL_COMMENTS`.

#### EDITION Clause

Specify the name of an existing edition to be commented.

You can query the data dictionary view `ALL_EDITION_COMMENTS` to view comments associated with editions that are accessible to the current user. You can query `DBA_EDITION_COMMENTS` to view comments associated with all editions in the database.

#### TABLE Clause

Specify the schema and name of the table or materialized view to be commented. If you omit `schema`, then Oracle Database assumes the table or materialized view is in your own schema.

 **Note:**

In earlier releases, you could use this clause to create a comment on a materialized view. You should now use the `COMMENT ON MATERIALIZED VIEW` clause for materialized views.

#### INDEXTYPE Clause

Specify the name of the indextype to be commented. If you omit `schema`, then Oracle Database assumes the indextype is in your own schema.

You can view the comments on a particular indextype by querying the data dictionary views `USER_INDEXTYPE_COMMENTS`, `DBA_INDEXTYPE_COMMENTS`, or `ALL_INDEXTYPE_COMMENTS`.

#### MATERIALIZED VIEW Clause

Specify the name of the materialized view to be commented. If you omit `schema`, then Oracle Database assumes the materialized view is in your own schema.

You can view the comments on a particular materialized view by querying the data dictionary views `USER_MVIEW_COMMENTS`, `DBA_MVIEW_COMMENTS`, or `ALL_MVIEW_COMMENTS`.

#### MINING MODEL

Specify the name of the mining model to be commented.

You can view the comments on a particular mining model by querying the `COMMENTS` column of the data dictionary views `USER_MINING_MODELS`, `DBA_MINING_MODELS`, or `ALL_MINING_MODELS`.

#### OPERATOR Clause

Specify the name of the operator to be commented. If you omit `schema`, then Oracle Database assumes the operator is in your own schema.

You can view the comments on a particular operator by querying the data dictionary views `USER_OPERATOR_COMMENTS`, `DBA_OPERATOR_COMMENTS`, or `ALL_OPERATOR_COMMENTS`.

**IS '*string*'**

Specify the text of the comment. Refer to "[Text Literals](#)" for a syntax description of '*string*'.

**Examples**

**Creating Comments: Example**

To insert an explanatory remark on the `job_id` column of the `employees` table, you might issue the following statement:

```
COMMENT ON COLUMN employees.job_id
    IS 'abbreviated job title';
```

To drop this comment from the database, issue the following statement:

```
COMMENT ON COLUMN employees.job_id IS '';
```

# 13

## SQL Statements: COMMIT to CREATE JAVA

This chapter contains the following SQL statements:

- [COMMIT](#)
- [CREATE ANALYTIC VIEW](#)
- [CREATE ATTRIBUTE DIMENSION](#)
- [CREATE AUDIT POLICY \(Unified Auditing\)](#)
- [CREATE CLUSTER](#)
- [CREATE CONTEXT](#)
- [CREATE CONTROLFILE](#)
- [CREATE DATABASE](#)
- [CREATE DATABASE LINK](#)
- [CREATE DIMENSION](#)
- [CREATE DIRECTORY](#)
- [CREATE DISKGROUP](#)
- [CREATE DOMAIN](#)
- [CREATE EDITION](#)
- [CREATE FLASHBACK ARCHIVE](#)
- [CREATE FUNCTION](#)
- [CREATE HIERARCHY](#)
- [CREATE INDEX](#)
- [CREATE INDEXTYPE](#)
- [CREATE INMEMORY JOIN GROUP](#)
- [CREATE JAVA](#)

### COMMIT

#### Purpose

Use the `COMMIT` statement to end your current transaction and make permanent all changes performed in the transaction. A **transaction** is a sequence of SQL statements that Oracle Database treats as a single unit. This statement also erases all savepoints in the transaction and releases transaction locks.

Until you commit a transaction:

- You can see any changes you have made during the transaction by querying the modified tables, but other users cannot see the changes. After you commit the

transaction, the changes are visible to other users' statements that execute after the commit.

- You can roll back (undo) any changes made during the transaction with the ROLLBACK statement (see [ROLLBACK](#) ).

Oracle Database issues an implicit COMMIT under the following circumstances:

- Before any syntactically valid data definition language (DDL) statement, even if the statement results in an error
- After any data definition language (DDL) statement that completes without an error

You can also use this statement to:

- Commit an in-doubt distributed transaction manually
- Terminate a read-only transaction begun by a SET TRANSACTION statement

Oracle recommends that you explicitly end every transaction in your application programs with a COMMIT or ROLLBACK statement, including the last transaction, before disconnecting from Oracle Database. If you do not explicitly commit the transaction and the program terminates abnormally, then the last uncommitted transaction is automatically rolled back.

A normal exit from most Oracle utilities and tools causes the current transaction to be committed. A normal exit from an Oracle precompiler program does not commit the transaction and relies on Oracle Database to roll back the current transaction.

 **See Also:**

- [Oracle Database Concepts](#) for more information on transactions
- [SET TRANSACTION](#) for more information on specifying characteristics of a transaction

### Prerequisites

You need no privileges to commit your current transaction.

To manually commit a distributed in-doubt transaction that you originally committed, you must have FORCE TRANSACTION system privilege. To manually commit a distributed in-doubt transaction that was originally committed by another user, you must have FORCE ANY TRANSACTION system privilege.

## Syntax

**commit::=**

## Semantics

### COMMIT

All clauses after the COMMIT keyword are optional. If you specify only COMMIT, then the default is COMMIT WORK WRITE WAIT IMMEDIATE.

### WORK

The WORK keyword is supported for compliance with standard SQL. The statements COMMIT and COMMIT WORK are equivalent.

### COMMENT Clause

This clause is supported for backward compatibility. Oracle recommends that you use named transactions instead of commit comments.

#### See Also:

[SET TRANSACTION](#) and *Oracle Database Concepts* for more information on named transactions

Specify a comment to be associated with the current transaction. The 'text' is a quoted literal of up to 255 bytes that Oracle Database stores in the data dictionary view DBA\_2PC\_PENDING along with the transaction ID if a distributed transaction becomes in doubt. This comment can help you diagnose the failure of a distributed transaction.

#### See Also:

[COMMENT](#) for more information on adding comments to SQL statements

## WRITE Clause

Use this clause to specify the priority with which the redo information generated by the commit operation is written to the redo log. This clause can improve performance by reducing latency, thus eliminating the wait for an I/O to the redo log. Use this clause to improve response time in environments with stringent response time requirements where the following conditions apply:

- The volume of update transactions is large, requiring that the redo log be written to disk frequently.
- The application can tolerate the loss of an asynchronously committed transaction.
- The latency contributed by waiting for the redo log write to occur contributes significantly to overall response time.

You can specify the `WAIT | NOWAIT` and `IMMEDIATE | BATCH` clauses in any order.

 **Note:**

If you omit this clause, then the behavior of the commit operation is controlled by the `COMMIT_LOGGING` and `COMMIT_WAIT` initialization parameters, if they have been set.

## WAIT | NOWAIT

Use these clauses to specify when control returns to the user.

- The `WAIT` parameter ensures that the commit will return only after the corresponding redo is persistent in the online redo log. Whether in `BATCH` or `IMMEDIATE` mode, when the client receives a successful return from this `COMMIT` statement, the transaction has been committed to durable media. A crash occurring after a successful write to the log can prevent the success message from returning to the client. In this case the client cannot tell whether or not the transaction committed.
- The `NOWAIT` parameter causes the commit to return to the client whether or not the write to the redo log has completed. This behavior can increase transaction throughput. With the `WAIT` parameter, if the commit message is received, then you can be sure that no data has been lost.

 **Note:**

With `NOWAIT`, a crash occurring after the commit message is received, but before the redo log record(s) are written, can falsely indicate to a transaction that its changes are persistent.

If you omit this clause, then the transaction commits with the `WAIT` behavior.

## IMMEDIATE | BATCH

Use these clauses to specify when the redo is written to the log.

- The `IMMEDIATE` parameter causes the log writer process (LGWR) to write the transaction's redo information to the log. This operation option forces a disk I/O, so it can reduce transaction throughput.
- The `BATCH` parameter causes the redo to be buffered to the redo log, along with other concurrently executing transactions. When sufficient redo information is collected, a disk write of the redo log is initiated. This behavior is called "group commit", as redo for multiple transactions is written to the log in a single I/O operation.

If you omit this clause, then the transaction commits with the `IMMEDIATE` behavior.

#### **See Also:**

*Oracle Database Concepts* for more information on asynchronous commit

### **FORCE Clause**

In a distributed database system, the `FORCE string [, integer]` clause lets you manually commit an in-doubt distributed transaction. The transaction is identified by the '`string`' containing its local or global transaction ID. To find the IDs of such transactions, query the data dictionary view `DBA_2PC_PENDING`. You can use `integer` to specifically assign the transaction a system change number (SCN). If you omit `integer`, then the transaction is committed using the current SCN.

#### **Note:**

A `COMMIT` statement with a `FORCE` clause commits only the specified transactions. Such a statement does not affect your current transaction.

#### **See Also:**

*Oracle Database Administrator's Guide* for more information on these topics

### **Examples**

#### **Committing an Insert: Example**

This statement inserts a row into the `hr.regions` table and commits this change:

```
INSERT INTO regions VALUES (5, 'Antarctica');  
COMMIT WORK;
```

To commit the same insert operation and instruct the database to buffer the change to the redo log, without initiating disk I/O, use the following `COMMIT` statement:

```
COMMIT WRITE BATCH;
```

#### **Commenting on COMMIT: Example**

The following statement commits the current transaction and associates a comment with it:

```
COMMIT
    COMMENT 'In-doubt transaction Code 36, Call (415) 555-2637';
```

If a network or machine failure prevents this distributed transaction from committing properly, then Oracle Database stores the comment in the data dictionary along with the transaction ID. The comment indicates the part of the application in which the failure occurred and provides information for contacting the administrator of the database where the transaction was committed.

### Forcing an In-Doubt Transaction: Example

The following statement manually commits a hypothetical in-doubt distributed transaction. Query the `V$CORRUPT_XID_LIST` data dictionary view to find the transaction IDs of corrupt transactions. You must have DBA privileges to view the `V$CORRUPT_XID_LIST` and to issue this statement.

```
COMMIT FORCE '22.57.53';
```

## CREATE ANALYTIC VIEW

### Purpose

Use the `CREATE ANALYTIC VIEW` statement to create an analytic view. An analytic view specifies the source of its fact data and defines measures that describe calculations or other analytic operations to perform on the data. An analytic view also specifies the attribute dimensions and hierarchies that define the rows of the analytic view.

### Prerequisites

To create an analytic view in your own schema, you must have the `CREATE ANALYTIC VIEW` system privilege. To create an analytic view in another user's schema, you must have the `CREATE ANY ANALYTIC VIEW` system privilege.

### Syntax

`create_analytic_view::=`

*classification\_clause ::=*

*using\_clause ::=*

*source\_clause ::=*

*dim\_by\_clause ::=*

*dim\_key ::=*

**dim\_ref::=**

**hier\_ref::=**

**measures\_clause::=**

**av\_measure::=**

**base\_meas\_clause::=**

**calc\_meas\_clause::=**

**meas\_aggregate\_clause::=**

***default\_measure\_clause ::=***

***default\_aggregate\_clause ::=***

***cache\_clause ::=***

***cache\_specification ::=***

***levels\_clause ::=***

***level\_specification ::=***

***level\_group\_type ::=***

**fact\_columns\_clause ::=**

**qry\_transform\_clause ::=**

## Semantics

### OR REPLACE

Specify `OR REPLACE` to replace an existing definition of an analytic view with a different definition.

### FORCE and NOFORCE

Specify `FORCE` to force the creation of the analytic view even if it does not successfully compile. If you specify `NOFORCE`, then the analytic view must compile successfully, otherwise an error occurs. The default is `NOFORCE`.

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the analytic view does not exist, a new analytic view is created at the end of the statement.
- If the analytic view exists, this is the analytic view you have at the end of the statement. A new one is not created because the older one is detected.

You can have **one** of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

### schema

Specify the schema in which to create the analytic view. If you do not specify a schema, then Oracle Database creates the analytic view in your own schema.

***analytic\_view\_name***

Specify a name for the analytic view.

**SHARING**

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- METADATA - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- NONE - The object is not shared and can only be accessed in the application root.

***classification\_clause***

Use the classification clause to specify values for the `CAPTION` or `DESCRIPTION` classifications and to specify user-defined classifications. Classifications provide descriptive metadata that applications may use to provide information about analytic views and their components.

You may specify any number of classifications for the same object. A classification can have a maximum length of 4000 bytes.

For the `CAPTION` and `DESCRIPTION` classifications, you may use the DDL shortcuts `CAPTION 'caption'` and `DESCRIPTION 'description'` or the full classification syntax.

You may vary the classification values by language. To specify a language for the `CAPTION` or `DESCRIPTION` classification, you must use the full syntax. If you do not specify a language, then the language value for the classification is `NULL`. The language value must either be `NULL` or a valid `NLS_LANGUAGE` value.

***using\_clause***

Use this clause to declare the sources that you want to use to build the analytic view.

***source\_clause***

You can specify any of the following sources to build an analytic view:

- A fact table or a view.
- External tables and remote tables.
- A table or a view in another schema. You can specify an alias for the table or the view.

**REMOTE**

Specify `REMOTE` on a given source to indicate to the analytic view that the given source is backed by remote data and should be optimized as remote data.

***dim\_by\_clause***

Specify the attribute dimensions of the analytic view.

### ***dim\_key***

Specify an attribute dimension, columns of the fact table, columns of the attribute dimension, and hierarchies that are related in the analytic view.

With the `KEY` keyword, specify one or more columns in the fact table.

With the `REFERENCES` keyword, specify attributes of the attribute dimensions that the analytic view is dimensioned by. Each attribute must be a level key. The `DISTINCT` keyword supports the use of denormalized fact tables, in which the attribute dimension and fact data are in the same table. Use `REFERENCES DISTINCT` when an attribute dimension is defined using the fact table.

With the `HIERARCHIES` keyword, specify the hierarchies in the analytic view that use the attribute dimension.

### ***dim\_ref***

Specify an attribute dimension. You can specify an alias for an attribute dimension, which is required if you use the same dimension more than once or if you use multiple dimensions with the same name from different schemas.

### ***hier\_ref***

Specify a hierarchy. You can specify an alias for a hierarchy. You can specify one of the hierarchies in the list as the default. If you do not specify a default, the first hierarchy in the list is the default.

### ***measures\_clause***

Specify the measures for the analytic view.

#### ***av\_measure***

Define a measure using either a single fact column or an expression over measures in this analytic view. A measure can be either a base measure or a calculated measure.

#### ***base\_measure\_clause***

Define a base measure by optionally specifying a fact column or a `meas_aggregate_clause`, or both. If you do not specify a fact column, then the analytic view uses the column of the fact table that has the same name as the measure. If a column by the same name does not exist, an error is raised.

#### ***calc\_measure\_clause***

Define a calculated measure by specifying an analytic view expression. The expression may reference other measures in the analytic view, but may not reference fact columns. Calculated measures do not have an aggregate clause because they're computed over the aggregated base measures.

For the syntax and descriptions of analytic view expressions, see [Analytic View Expressions](#).

#### ***default\_measure\_clause***

Specify a measure to use as the default measure for the analytic view. If you do not specify a measure, the first measure defined is the default.

***meas\_aggregate\_clause***

Specify a default aggregation function for a base measure. If you do not specify an aggregation function, then the function specified by the *default\_aggregate\_clause* is used.

***aggr\_function***

The functions that you can aggregate by in the *meas\_aggregate\_clause* and *default\_aggregate\_clause* are the following: APPROX\_COUNT\_DISTINCT, APPROX\_COUNT\_DISTINCT\_ AGG, AVG, COUNT, MAX, MIN, STDDEV, STDDEV\_POP, STDDEV\_SAMP, SUM, VAR\_POP, VAR\_SAMP, and VARIANCE.

***default\_aggregate\_clause***

Specify a default aggregation function for all of the base measures in the analytic view. If you do not specify a default aggregation function, then the default value is SUM.

***cache\_clause***

Specify a cache clause to improve query response time when an appropriate materialized view is available. You can specify one or more cache specifications.

***cache\_specification***

Specify one or more measure groups for a cache clause. To include all measure groups, specify ALL. Each measure group can contain one or more measures and one or more level groupings. A level grouping can contain one or more level specifications.

***level\_specification***

Specify one or more levels for a level grouping of a measure group for a cache specification. Specify only one level per hierarchy. A materialized view must exist that contains the aggregated values for the hierarchy level.

***level\_group\_type***

If you specify the USING clause, then the given table will be directly used at query time, if the analytic view determines that this is the best cache to use for the query. The typical shape of the cache is a column for each measure in the MEASURE GROUP plus a column per level key of each level in the cache. There is one row per member combination, across all given levels, that has at least one contributing row from the fact table. The column names of the given table must match a specific format so that the analytic view can identify which columns line up with which measures and level keys. The names of the columns can be retrieved from the DBMS\_HIERARCHY package using the method GET\_MV\_SQL\_FOR\_AV\_CACHE.

This method takes in the cache to generate SQL for and returns the SQL text for the cache. This SQL text can be used to create a materialized view for the cache. It can also be used to create an aggregate table using CREATE TABLE AS.

At compile time of the analytic view, the following checks will be made in regard to the materialized table:

- The table must exist and be accessible by the owner of the analytic view
- The columns of the table must include the expected cache columns

### ***fact\_columns\_clause***

Specify this clause to explicitly state the fact columns that can be accessed by the derived analytic view. You can aggregate any columns of the fact table that appear in *fact\_columns\_clause* at query time with the aggregation operator specified in the derived analytic view.

If an alias is provided for the fact column, then the alias name must be used in the derived analytic view. The alias defaults to the fact column name if not specified.

It is a semantic analysis error, if two or more fact columns are specified with the same name.

If you do not specify this clause, then no fact columns can be accessed for aggregation by the derived analytic view. This is the default.

### ***qry\_transform\_clause***

Specify this clause on an analytic view, if you want the view to participate in detecting queries that match its semantic model and transform it into an equivalent analytic view query if appropriate.

### **Restrictions**

You cannot use *qry\_transform\_clause* on an analytic view in the following cases:

- When the analytic view contains an attribute dimension with more than one dimension table (either a snowflake or starflake schema)
- When a dimension table joins to the fact table at a level that is above the leaf level of the dimension (i.e. a REFERENCES DISTINCT join)
- When NORELY is specified and one or more base tables are remote tables

The new clause allows for an optional RELY or NORELY keyword. The default is NORELY.

The analytic view metadata can be viewed as a set of constraints on the underlying data. These constraints are not enforced by the database, but can be checked using the DBMS\_HIERARCHY.VALIDATE\_ANALYTIC\_VIEW procedure.

The RELY keyword indicates that the constraints implied on the data by the analytic view metadata can be relied upon without validation when being considered for base table transform. If NORELY is specified, then the data must be in a valid state in relation to the metadata in order for the base table transform to take place.

### **Examples**

The following is a description of the SALES\_FACT table:

```
desc SALES_FACT
Name          Null? Type
-----
MONTH_ID      VARCHAR2(10)
CATEGORY_ID   NUMBER(6)
STATE_PROVINCE_ID  VARCHAR2(120)
UNITS         NUMBER(6)
SALES         NUMBER(12,2)
```

The following example creates the SALES\_AV analytic view using the SALES\_FACT table:

```

CREATE OR REPLACE ANALYTIC VIEW sales_av
USING sales_fact
DIMENSION BY
  (time_attr_dim                                -- An attribute dimension of time
data
  KEY month_id REFERENCES month_id
  HIERARCHIES (
    time_hier DEFAULT),
  product_attr_dim                               -- An attribute dimension of
product data
  KEY category_id REFERENCES category_id
  HIERARCHIES (
    product_hier DEFAULT),
  geography_attr_dim                            -- An attribute dimension of store
data
  KEY state_province_id
  REFERENCES state_province_id HIERARCHIES (
    geography_hier DEFAULT)
)
MEASURES
  (sales FACT sales,                           -- A base measure
  units FACT units,                          -- A base measure
  sales_prior_period AS                      -- Calculated measures
    (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1)),
  sales_year_ago AS
    (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1
      ACROSS ANCESTOR AT LEVEL year)),
  chg_sales_year_ago AS
    (LAG_DIFF(sales) OVER (HIERARCHY time_hier OFFSET 1
      ACROSS ANCESTOR AT LEVEL year)),
  pct_chg_sales_year_ago AS
    (LAG_DIFF_PERCENT(sales) OVER (HIERARCHY time_hier OFFSET 1
      ACROSS ANCESTOR AT LEVEL year)),
  sales_qtr_ago AS
    (LAG(sales) OVER (HIERARCHY time_hier OFFSET 1
      ACROSS ANCESTOR AT LEVEL quarter)),
  chg_sales_qtr_ago AS
    (LAG_DIFF(sales) OVER (HIERARCHY time_hier OFFSET 1
      ACROSS ANCESTOR AT LEVEL quarter)),
  pct_chg_sales_qtr_ago AS
    (LAG_DIFF_PERCENT(sales) OVER (HIERARCHY time_hier OFFSET 1
      ACROSS ANCESTOR AT LEVEL quarter))
)
DEFAULT MEASURE SALES;

```

## CREATE ATTRIBUTE DIMENSION

### Purpose

Use the CREATE ATTRIBUTE DIMENSION statement to create an attribute dimension. An attribute dimension specifies dimension members for one or more analytic view hierarchies. It

specifies the data source it is using and the members it includes. It specifies levels for its members and determines attribute relationships between levels.

### Prerequisites

To create an attribute dimension in your own schema, you must have the `CREATE ATTRIBUTE DIMENSION` system privilege. To create an attribute dimension in another user's schema, you must have the `CREATE ANY ATTRIBUTE DIMENSION` system privilege.

### Syntax

*create\_attribute\_dimension ::=*

*classification\_clause ::=*

*attr\_dim\_using\_clause ::=*

**source\_clause ::=**

**join\_path\_clause ::=**

**join\_condition ::=**

**join\_condition\_elem ::=**

**attributes\_clause ::=**

**attr\_dim\_attributes\_clause ::=**

**attr\_dim\_level\_clause ::=**

**key\_clause ::=**

***alternate\_key\_clause ::=***

***dim\_order\_clause ::=***

***all\_clause ::=***

## Semantics

### OR REPLACE

Specify `OR REPLACE` to replace an existing definition of an attribute dimension with a different definition.

### FORCE and NOFORCE

Specify `FORCE` to force the creation of the attribute dimension even if it does not successfully compile. If you specify `NOFORCE`, then the attribute dimension must compile successfully, otherwise an error occurs. The default is `NOFORCE`.

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the attribute dimension does not exist, a new attribute dimension is created at the end of the statement.
- If the attribute dimension exists, this is the attribute dimension you have at the end of the statement. A new one is not created because the older one is detected.

You can have **one** of OR REPLACE or IF NOT EXISTS in a statement at a time. Using both OR REPLACE with IF NOT EXISTS in the very same statement results in the following error: ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.

Using IF EXISTS with CREATE results in ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.

### ***schema***

Specify the schema in which to create the attribute dimension. If you do not specify a schema, then Oracle Database creates the attribute dimension in your own schema.

### ***attr\_dimension***

Specify a name for the attribute dimension.

### **SHARING**

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- METADATA - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- NONE - The object is not shared and can only be accessed in the application root.

### ***classification\_clause***

Use the classification clause to specify values for the CAPTION or DESCRIPTION classifications and to specify user-defined classifications. Classifications provide descriptive metadata that applications may use to provide information about analytic views and their components.

You may specify any number of classifications for the same object. A classification can have a maximum length of 4000 bytes.

For the CAPTION and DESCRIPTION classifications, you may use the DDL shortcuts CAPTION 'caption' and DESCRIPTION 'description' or the full classification syntax.

You may vary the classification values by language. To specify a language for the CAPTION or DESCRIPTION classification, you must use the full syntax. If you do not specify a language, then the language value for the classification is NULL. The language value must either be NULL or a valid NLS\_LANGUAGE value.

### **DIMENSION TYPE**

An attribute dimension may be either a STANDARD or a TIME type. A STANDARD type attribute dimension has STANDARD type levels. Each level of a TIME type attribute dimension is one of the time types. The default DIMENSION\_TYPE is STANDARD.

### ***attr\_dim\_using\_clause***

Use this clause to declare the sources that you want to use to create the attribute dimension.

#### ***source\_clause***

You may specify the following sources:

- A table or a view.
- An alias for the table or the view by using the `AS` keyword.
- A join path. Use join paths to specify joins when the attribute dimension uses tables organized in a snowflake schema.

#### **REMOTE**

Specify `REMOTE` on a given source to indicate that the source is backed by remote data and should be optimized as remote data.

#### ***join\_path\_clause***

The join path clause specifies a join condition between columns in different tables. The name for the join path specified by the `join_path_name` argument must be unique for each join path included in the `USING` clause.

#### ***join\_condition***

A join condition consists of one or more join condition elements; each additional join condition element is included by an `AND` operation.

#### ***join\_condition\_element***

In a join condition element, the column references on the left-hand-side must come from a different table than the column references on the right-hand-side.

#### ***attributes\_clause***

Specify one or more `attr_dim_attribute_clause` clauses.

#### ***attr\_dim\_attribute\_clause***

Specify a column from the `attr_dim_using_clause` source. The attribute has the name of the column unless you specify an alias using the `AS` keyword. You may specify classifications for each attribute.

#### ***attr\_dim\_level\_clause***

Specify a level in the attribute dimension. A level specifies key and optional alternate key attributes that provide the members of the level.

If the key attribute has no `NONE` values, then you may specify `NOT NULL`, which is the default. If it does have one or more `NONE` values, then specify `SKIP WHEN NULL`.

#### **LEVEL TYPE**

A `STANDARD` type attribute dimension has `STANDARD` type levels. You do not need to specify a `LEVEL TYPE` for a `STANDARD` type attribute dimension.

In a `TIME` type attribute dimension, you must specify a level type. The type of the level may be one of the time types. You must specify a time type even if the values of the level members are not of that type. For example, you may have a `SEASON` level with values that are the names of seasons. In defining the level, you must specify any one of the time level types, such as `QUARTERS`. An application may use the level type designations for whatever purpose it chooses.

## DETERMINES

With the `DETERMINES` keyword, you may specify other attributes of the attribute dimension that this level determines. If an attribute has only one value for each value of another attribute, then the value of the first attribute determines the value of the other attribute. For example, the `QUARTER_ID` attribute has only one value for each value of the `MONTH_ID` attribute, so you can include the `QUARTER_ID` attribute in the `DETERMINES` phrase of the `MONTHS` level.

### *key\_clause*

Specify one or more attributes as the key for the level.

### *alternate\_key\_clause*

Specify one or more attributes as the alternate key for the level.

### *dim\_order\_clause*

Specify the ordering of the members of the level.

### *all\_clause*

Optionally specify `MEMBER NAME`, `MEMBER CAPTION`, and `MEMBER DESCRIPTION` values for the implicit ALL level. By default, the `MEMBER NAME` value is ALL.

## Examples

The following example describes the `TIME_DIM` table:

```
desc TIME_DIM
```

Name	Null?	Type
MONTH_ID		VARCHAR2(10)
CATEGORY_ID		NUMBER(6)
STATE_PROVINCE_ID		VARCHAR2(120)
UNITS		NUMBER(6)
SALES		NUMBER(12,2)
YEAR_ID	NOT NULL	VARCHAR2(30)
YEAR_NAME	NOT NULL	VARCHAR2(40)
YEAR_END_DATE		DATE
QUARTER_ID	NOT NULL	VARCHAR2(30)
QUARTER_NAME	NOT NULL	VARCHAR2(40)
QUARTER_END_DATE		DATE
QUARTER_OF_YEAR		NUMBER
MONTH_ID	NOT NULL	VARCHAR2(30)
MONTH_NAME	NOT NULL	VARCHAR2(40)
MONTH_END_DATE		DATE
MONTH_OF_YEAR		NUMBER

MONTH_LONG_NAME	VARCHAR2(30)
SEASON	VARCHAR2(10)
SEASON_ORDER	NUMBER(38)
MONTH_OF_QUARTER	NUMBER(38)

The following example creates a `TIME` type attribute dimension, using columns from the `TIME_DIM` table:

```
CREATE OR REPLACE ATTRIBUTE DIMENSION time_attr_dim
DIMENSION TYPE TIME
USING time_dim
ATTRIBUTES
  (year_id
    CLASSIFICATION caption VALUE 'YEAR_ID'
    CLASSIFICATION description VALUE 'YEAR ID',
   year_name
    CLASSIFICATION caption VALUE 'YEAR_NAME'
    CLASSIFICATION description VALUE 'Year',
   year_end_date
    CLASSIFICATION caption VALUE 'YEAR_END_DATE'
    CLASSIFICATION description VALUE 'Year End Date',
   quarter_id
    CLASSIFICATION caption VALUE 'QUARTER_ID'
    CLASSIFICATION description VALUE 'QUARTER ID',
   quarter_name
    CLASSIFICATION caption VALUE 'QUARTER_NAME'
    CLASSIFICATION description VALUE 'Quarter',
   quarter_end_date
    CLASSIFICATION caption VALUE 'QUARTER_END_DATE'
    CLASSIFICATION description VALUE 'Quarter End Date',
   quarter_of_year
    CLASSIFICATION caption VALUE 'QUARTER_OF_YEAR'
    CLASSIFICATION description VALUE 'Quarter of Year',
   month_id
    CLASSIFICATION caption VALUE 'MONTH_ID'
    CLASSIFICATION description VALUE 'MONTH ID',
   month_name
    CLASSIFICATION caption VALUE 'MONTH_NAME'
    CLASSIFICATION description VALUE 'Month',
   month_long_name
    CLASSIFICATION caption VALUE 'MONTH_LONG_NAME'
    CLASSIFICATION description VALUE 'Month Long Name',
   month_end_date
    CLASSIFICATION caption VALUE 'MONTH_END_DATE'
    CLASSIFICATION description VALUE 'Month End Date',
   month_of_quarter
    CLASSIFICATION caption VALUE 'MONTH_OF_QUARTER'
    CLASSIFICATION description VALUE 'Month of Quarter',
   month_of_year
    CLASSIFICATION caption VALUE 'MONTH_OF_YEAR'
    CLASSIFICATION description VALUE 'Month of Year',
   season
    CLASSIFICATION caption VALUE 'SEASON'
    CLASSIFICATION description VALUE 'Season',
```

```

season_order
    CLASSIFICATION caption VALUE 'SEASON_ORDER'
    CLASSIFICATION description VALUE 'Season Order')
LEVEL month
    LEVEL TYPE MONTHS
    CLASSIFICATION caption VALUE 'MONTH'
    CLASSIFICATION description VALUE 'Month'
    KEY month_id
    MEMBER NAME month_name
    MEMBER CAPTION month_name
    MEMBER DESCRIPTION month_long_name
    ORDER BY month_end_date
    DETERMINES (month_end_date,
        quarter_id,
        season,
        season_order,
        month_of_year,
        month_of_quarter)
LEVEL quarter
    LEVEL TYPE QUARTERS
    CLASSIFICATION caption VALUE 'QUARTER'
    CLASSIFICATION description VALUE 'Quarter'
    KEY quarter_id
    MEMBER NAME quarter_name
    MEMBER CAPTION quarter_name
    MEMBER DESCRIPTION quarter_name
    ORDER BY quarter_end_date
    DETERMINES (quarter_end_date,
        quarter_of_year,
        year_id)
LEVEL year
    LEVEL TYPE YEARS
    CLASSIFICATION caption VALUE 'YEAR'
    CLASSIFICATION description VALUE 'Year'
    KEY year_id
    MEMBER NAME year_name
    MEMBER CAPTION year_name
    MEMBER DESCRIPTION year_name
    ORDER BY year_end_date
    DETERMINES (year_end_date)
LEVEL season
    LEVEL TYPE QUARTERS
    CLASSIFICATION caption VALUE 'SEASON'
    CLASSIFICATION description VALUE 'Season'
    KEY season
    MEMBER NAME season
    MEMBER CAPTION season
    MEMBER DESCRIPTION season
LEVEL month_of_quarter
    LEVEL TYPE MONTHS
    CLASSIFICATION caption VALUE 'MONTH_OF_QUARTER'
    CLASSIFICATION description VALUE 'Month of Quarter'
    KEY month_of_quarter;

```

The following example describes the PRODUCT\_DIM table:

```
desc PRODUCT_DIM

Name          Null?    Type
-----  -----
DEPARTMENT_ID NOT NULL NUMBER
DEPARTMENT_NAME NOT NULL VARCHAR2(100)
CATEGORY_ID    NOT NULL NUMBER
CATEGORY_NAME   NOT NULL VARCHAR2(100)
```

The following example creates a STANDARD type attribute dimension, using columns from the PRODUCT\_DIM table:

```
CREATE OR REPLACE ATTRIBUTE DIMENSION product_attr_dim
USING product_dim
ATTRIBUTES
(department_id,
 department_name,
 category_id,
 category_name)
LEVEL DEPARTMENT
KEY department_id
ALTERNATE KEY department_name
MEMBER NAME department_name
MEMBER CAPTION department_name
ORDER BY department_name
LEVEL CATEGORY
KEY category_id
ALTERNATE KEY category_name
MEMBER NAME category_name
MEMBER CAPTION category_name
ORDER BY category_name
DETERMINES (department_id)
ALL MEMBER NAME 'ALL PRODUCTS';
```

The following example describes the GEOGRAPHY\_DIM table:

```
desc GEOGRAPHY_DIM

Name          Null?    Type
-----  -----
DEPARTMENT_ID NOT NULL NUMBER
DEPARTMENT_NAME NOT NULL VARCHAR2(100)
CATEGORY_ID    NOT NULL NUMBER
CATEGORY_NAME   NOT NULL VARCHAR2(100)
REGION_ID      NOT NULL VARCHAR2(120)
REGION_NAME     NOT NULL VARCHAR2(100)
COUNTRY_ID      NOT NULL VARCHAR2(2)
COUNTRY_NAME    NOT NULL VARCHAR2(120)
STATE_PROVINCE_ID NOT NULL VARCHAR2(120)
STATE_PROVINCE_NAME NOT NULL VARCHAR2(400)
```

The following example creates an STANDARD type attribute dimension, using columns from the GEOGRAPHY\_DIM table:

```
CREATE OR REPLACE ATTRIBUTE DIMENSION geography_attr_dim
  USING geography_dim
  ATTRIBUTES
    (region_id,
     region_name,
     country_id,
     country_name,
     state_province_id,
     state_province_name)
  LEVEL REGION
    KEY region_id
    ALTERNATE KEY region_name
    MEMBER NAME region_name
    MEMBER CAPTION region_name
    ORDER BY region_name
  LEVEL COUNTRY
    KEY country_id
    ALTERNATE KEY country_name
    MEMBER NAME country_name
    MEMBER CAPTION country_name
    ORDER BY country_name
    DETERMINES (region_id)
  LEVEL STATE_PROVINCE
    KEY state_province_id
    ALTERNATE KEY state_province_name
    MEMBER NAME state_province_name
    MEMBER CAPTION state_province_name
    ORDER BY state_province_name
    DETERMINES (country_id)
  ALL MEMBER NAME 'ALL CUSTOMERS';
```

## CREATE AUDIT POLICY (Unified Auditing)

This section describes the CREATE AUDIT POLICY statement for **unified auditing**. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to *Oracle Database Security Guide* for more information on unified auditing.

### Purpose

Use the CREATE AUDIT POLICY statement to create a unified audit policy.

**See Also:**

- [ALTER AUDIT POLICY \(Unified Auditing\)](#)
- [DROP AUDIT POLICY \(Unified Auditing\)](#)
- [AUDIT \(Unified Auditing\)](#)
- [NOAUDIT \(Unified Auditing\)](#)

**Prerequisites**

You must have the `AUDIT SYSTEM` system privilege or the `AUDIT_ADMIN` role.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To create a common unified audit policy, you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role. To create a local unified audit policy, you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role, or you must have the locally granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` local role in the container to which you are connected.

**Syntax**

***create\_audit\_policy ::=***

**Note:**

You must specify at least one of the clauses `privilege_audit_clause`, `action_audit_clause`, or `role_audit_clause`.

(*privilege\_audit\_clause::=*, *action\_audit\_clause::=*, *role\_audit\_clause::=*)

**privilege\_audit\_clause ::=**

**action\_audit\_clause ::=**

**Note:**

You can specify only the *standard\_actions* clause, only the *component\_actions* clause, or both clauses in either order, but you can specify each clause at most once.

**standard\_actions ::=**

**component\_actions ::=**

***role\_audit\_clause::=*****Semantics*****policy***

Specify the name of the unified audit policy to be created. The name of the policy must begin with the value of the `COMMON_USER_PREFIX` initialization parameter. The default value of the `COMMON_USER_PREFIX` parameter is `c##`.

The length of the audit policy name cannot exceed 128 bytes and must contain ASCII characters only.

These rules apply for application common audit policies as well. In this case, the value of the `COMMON_USER_PREFIX` is fetched from the application root. The default value in application root is an empty string.

The name must also satisfy the requirements listed in "[Database Object Naming Rules](#)".

You can find the names of all unified audit policies by querying the `AUDIT_UNIFIED_POLICIES` view.

 **See Also:**

*Oracle Database Reference* for more information on the `AUDIT_UNIFIED_POLICIES` view

***privilege\_audit\_clause***

Use this clause to audit one or more system privileges. For `system_privilege`, specify a valid system privilege. To view all valid system privileges, query the `NAME` column of the `SYSTEM_PRIVILEGE_MAP` view.

Only those SQL statements are audited, that successfully use system privileges. If a statement does not make use of a system privilege, it does not get audited with the `privilege_audit_clause`.

**Restriction on Auditing System Privileges**

You cannot audit the following system privileges: `INHERIT ANY PRIVILEGES`, `SYSASM`, `SYSBACKUP`, `SYSDBA`, `SYSDG`, `SYSKM`, `SYSRAC`, and `SYSOPER`.

***action\_audit\_clause***

Use this clause to specify one or more actions to be audited. Use the `standard_actions` clause to audit actions on standard RDBMS objects and to audit standard RDBMS system actions for the database. Use the `component_actions` clause to audit actions for components.

***standard\_actions***

Use this clause to audit actions on standard RDBMS objects and to audit standard RDBMS system actions for the database.

You can also create unified audit policies to audit individual columns in tables and views. For examples on auditing columns see [Examples](#)

Note that column level audit policies generate audit records whenever the column is accessed.

***object\_action ON***

Use this clause to audit an action on the specified object. For *object\_action*, specify the action to be audited. [Table 13-1](#) lists the actions that can be audited on each type of object.

**ALL ON**

Use this clause to audit all actions on the specified object. All of the actions listed in [Table 13-1](#) for the type of object that you specify in the *ON* clause will be audited.

**ON Clause**

Use the *ON* clause to specify the object to be audited. Directories and data mining models are identified separately because they reside in separate namespaces. To audit actions on a directory, specify *ON DIRECTORY directory\_name*. To audit actions on a data mining model, specify *ON MINING MODEL object\_name*. To audit actions on the other types of objects listed in [Table 13-1](#), specify *ON object\_name*. If you do not qualify *object\_name* with *schema*, then the database assumes the object is in your own schema.

**Table 13-1 Unified Auditing Objects and Actions**

Type of Object	Actions
Directory	AUDIT, GRANT, READ
Function	AUDIT, EXECUTE (Notes 1 and 2), GRANT
Java Schema Objects (Source, Class, Resource)	AUDIT, EXECUTE, GRANT
Library	EXECUTE, GRANT
Materialized Views	ALTER, AUDIT, COMMENT, DELETE, INDEX, INSERT, LOCK, SELECT, UPDATE
Mining Model	AUDIT, COMMENT, GRANT, RENAME, SELECT
Object Type	ALTER, AUDIT, GRANT
Package	AUDIT, EXECUTE, GRANT
Procedure	AUDIT, EXECUTE (Notes 1 and 2), GRANT
Sequence	ALTER, AUDIT, GRANT, SELECT
Table	ALTER, AUDIT, COMMENT, DELETE, FLASHBACK, GRANT, INDEX, INSERT, LOCK, RENAME, SELECT, UPDATE, TRUNCATE
View	AUDIT, DELETE, FLASHBACK, GRANT, INSERT, LOCK, RENAME, SELECT, UPDATE

**Note 1:** When you audit the EXECUTE operation on a PL/SQL stored procedure or stored function, the database considers only its ability to find the procedure or function and authorize its execution when determining the success or failure of the operation for the purposes of auditing. Therefore, if you specify the WHENEVER NOT SUCCESSFUL clause, then only invalid object errors, non-existent object errors, and authorization failures are audited; errors encountered during the execution of the procedure or function are not audited. If you specify the WHENEVER SUCCESSFUL clause, then all executions that are not blocked by invalid object errors, non-existent object errors, or authorization failures are audited, regardless of whether errors are encountered during execution.

**Note 2:** To audit the failure of a recursive SQL operation inside a PL/SQL stored procedure or stored function, configure auditing for the SQL operation.

**Note 3:** The auditing of EXECUTE on a PL/SQL stored procedure, function, or package in the database happens during the instantiation phase of the procedure, function, or package.

Note 3: The auditing of the GRANT object audit option also audits the REVOKE audit option.

#### **system\_action**

Use this clause to audit a system action for the database. To view the valid values for system\_action, query the NAME column of the AUDITABLE\_SYSTEM\_ACTIONS view where COMPONENT is 'Standard'.

#### **Example: Audit CHANGE PASSWORD in Unified Auditing**

You can audit CHANGE\_PASSWORD system actions by configuring an audit policy to audit password changes. After you configure the audit policy, you must enable the audit policy.

#### **Example: Create Audit Policy to Audit System Action Change Password**

The following example creates an audit policy mypolicy to audit the action CHANGE\_PASSWORD:

```
CREATE AUDIT POLICY mypolicy ACTIONS CHANGE_PASSWORD;
-----
Audit policy created.
```

#### **Example: Enable Audit Policy Configured to Audit Password Changes**

The following statement enables the audit policy mypolicy:

```
AUDIT POLICY mypolicy;
```

The audit policy mypolicy will now audit CHANGE\_PASSWORD actions for both successful and unsuccessful changes of password.

#### **Example: Change Password**

A user hr\_usr with password hr\_pwd can connect to PDB hr\_pdb and change the password as follows:

```
CONNECT hr_usr/hr_pwd@hr_pdb;
PASSWORD
Changing password for hr_usr
Old password:
New password:
Retype new password:
Password changed.
```

In the SQL\*Plus example above, the command `PASSWORD` run by user `hr_usr` initiates a `CHANGE PASSWORD` action that generates an audit record.

### Example: Check Audit Trail for Password Changes

You can view the record by querying the `UNIFIED_AUDIT_TRAIL` as follows:

```
SELECT ACTION_NAME, UNIFIED_AUDIT_POLICIES, OBJECT_NAME FROM UNIFIED_AUDIT_TRAIL;  
  
ACTION_NAME  
-----  
UNIFIED_AUDIT_POLICIES  
-----  
OBJECT_NAME  
-----  
CHANGE_PASSWORD  
MYPOLICY  
HR_USR
```

Note that the audit policy `mypolicy` will not capture password changes via the `ALTER USER` statement.

#### **ALL**

Use this clause to audit all system actions for the database.

#### ***component\_actions***

Use this clause to audit actions for the following components: Oracle Data Pump, Oracle SQL\*Loader Direct Path Load, Oracle Label Security, Oracle Database Real Application Security, Oracle Database Vault, and the transmission protocol.

#### **DATAPUMP**

Use this clause to audit actions for Oracle Data Pump. For `component_action`, specify the action to be audited. To view the valid actions for Oracle Data Pump, query the `NAME` column of the `AUDITABLE_SYSTEM_ACTIONS` view where `COMPONENT` is Datapump. For example:

```
SELECT name FROM auditable_system_actions WHERE component = 'Datapump';
```

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle Data Pump.

#### **DIRECT\_LOAD**

Use this clause to audit actions for Oracle SQL\*Loader Direct Path Load. For `component_action`, specify the action to be audited. To view the valid actions for Oracle SQL\*Loader Direct Path Load, query the `NAME` column of the `AUDITABLE_SYSTEM_ACTIONS` view where `COMPONENT` is Direct path API. For example:

```
SELECT name FROM auditable_system_actions WHERE component = 'Direct path API';
```

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle SQL\*Loader Direct Path Load.

#### **OLS**

Use this clause to audit actions for Oracle Label Security. For `component_action`, specify the action to be audited. To view the valid actions for Oracle Label Security,

query the NAME column of the AUDITABLE\_SYSTEM\_ACTIONS view where COMPONENT is Label Security. For example:

```
SELECT name FROM auditable_system_actions WHERE component = 'Label Security';
```

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle Label Security.

#### XS

Use this clause to audit actions for Oracle Database Real Application Security. For *component\_action*, specify the action to be audited. To view the valid actions for Oracle Database Real Application Security, query the NAME column of the AUDITABLE\_SYSTEM\_ACTIONS view where COMPONENT is XS. For example:

```
SELECT name FROM auditable_system_actions WHERE component = 'XS';
```

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle Database Real Application Security.

#### DV

Use this clause to audit actions for Oracle Database Vault. For *component\_action*, specify the action to be audited. To view the valid actions for Oracle Database Vault, query the NAME column of the AUDITABLE\_SYSTEM\_ACTIONS view where COMPONENT is Database Vault. For example:

```
SELECT name FROM auditable_system_actions WHERE component = 'Database Vault';
```

For *object\_name*, specify the name of the Database Vault object to be audited.

Refer to *Oracle Database Security Guide* for complete information on auditing Oracle Database Vault.

#### PROTOCOL

Use the PROTOCOL component to audit FTP and HTTP messages.

##### Example 1: Audit all HTTP Messages

```
CREATE AUDIT POLICY mypolicy ACTIONS COMPONENT = PROTOCOL HTTP
AUDIT POLICY mypolicy
```

##### Example 2: Audit Failed FTP Messages

```
CREATE AUDIT POLICY mypolicy ACTIONS COMPONENT = PROTOCOL FTP
AUDIT POLICY mypolicy WHENEVER NOT SUCCESSFUL
```

##### Example 3: Audit HTTP Messages that had 401 AUTH Replies

```
CREATE AUDIT POLICY mypolicy ACTIONS COMPONENT = PROTOCOL AUTHENTICATION
AUDIT POLICY mypolicy
```

#### *role\_audit\_clause*

Use this clause to specify one or more roles to be audited. When you audit a role, Oracle Database audits all system privileges that are granted directly to the role. SQL statements that require the system privileges in order to succeed are audited. For *role*, specify either a user-defined (local or external) or predefined role. For a list of predefined roles, refer to *Oracle Database Security Guide*.

## WHEN Clause

Use this clause to control when the unified audit policy is enforced.

### *audit\_condition*

Specify a condition that determines if the unified audit policy is enforced. If *audit\_condition* evaluates to TRUE, then the policy is enforced. If FALSE, then the policy is not enforced.

The *audit\_condition* can have a maximum length of 4000 characters. It can contain expressions, as well as the following functions and conditions:

- Numeric functions: BITAND, CEIL, FLOOR, POWER
- Character functions returning character values: CONCAT, LOWER, UPPER
- Character functions returning number values: INSTR, LENGTH
- Environment and identifier functions: SYS\_CONTEXT, UID
- Comparison conditions: =, !=, <>, <, >, <=, >=
- Logical conditions: AND, OR
- Null conditions: IS [NOT] NULL
- [NOT] BETWEEN condition
- [NOT] IN condition

The *audit\_condition* must be enclosed in single quotation marks. If the *audit\_condition* contains a single quotation mark, then specify two single quotation marks instead. For example, to specify the following condition:

```
SYS_CONTEXT('USERENV', 'CLIENT_IDENTIFIER') = 'myclient'
```

Specify the following for '*audit\_condition*':

```
'SYS_CONTEXT('''USERENV'', ''CLIENT_IDENTIFIER'') = ''myclient'''
```

The EVALUATE PER clauses evaluate the audit condition per instance per container. For example, if a condition is evaluated in one container, it will be evaluated again in any other container even if the instance is same.

## EVALUATE PER STATEMENT

Specify this clause to evaluate the *audit\_condition* for each auditable statement for each instance in the container. If the *audit\_condition* evaluates to TRUE, then the unified audit policy is enforced for the statement. If FALSE, then the unified audit policy is not enforced for the statement.

## EVALUATE PER SESSION

Specify this clause to evaluate the *audit\_condition* once during the session. The *audit\_condition* is evaluated for the first auditable statement that is executed during the session. If the *audit\_condition* evaluates to TRUE, then the unified audit policy is enforced for all applicable statements for the rest of the session. If FALSE, then the unified audit policy is not enforced for all applicable statements for the rest of the session.

## EVALUATE PER INSTANCE

Specify this clause to evaluate the `audit_condition` once during the lifetime of the instance. The `audit_condition` is evaluated for the first auditable statement that is executed during the instance lifetime. If the `audit_condition` evaluates to TRUE, then the unified audit policy is enforced for all applicable statements for the rest of the lifetime of the instance. If FALSE, then the unified audit policy is not enforced for all applicable statements for the rest of the lifetime of the instance.

### ONLY TOLEVEL

Specify the ONLY TOLEVEL clause when you want to audit the SQL statements issued directly by a user.

SQL statements that are run from within a PL/SQL procedure are not considered top-level statements. You can audit top-level statements from all users, including user SYS.

For more see *Database Security Guide*.

### CONTAINER Clause

Use the CONTAINER clause to specify the scope of the unified audit policy.

- Specify CONTAINER = ALL to create a **common unified audit policy**. This type of policy is available to all pluggable databases (PDBs) in the CDB. The current container must be the root. If you specify the ACTIONS `object_action ON` or ACTIONS ALL ON clause, then you must specify a common object or an application common object.
- Specify CONTAINER = CURRENT to create a **local unified audit policy** in the current container. The current container can be the root or a PDB.

If you omit this clause, then CONTAINER = CURRENT is the default.

 **Note:**

You cannot alter the scope of a unified audit policy after it has been created.

### Examples

#### Auditing System Privileges: Example

The following statement creates unified audit policy `table_pol`, which audits the system privileges CREATE ANY TABLE and DROP ANY TABLE:

```
CREATE AUDIT POLICY table_pol
    PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE;
```

The following statement verifies that `table_pol` now appears in the `AUDIT_UNIFIED_POLICIES` view:

```
SELECT *
  FROM audit_unified_policies
 WHERE policy_name = 'TABLE_POL';
```

#### Auditing Actions on Objects: Examples

The following statement creates unified audit policy `dml_pol`, which audits DELETE, INSERT, and UPDATE actions on table `hr.employees`, and all auditable actions on table `hr.departments`:

```
CREATE AUDIT POLICY dml_pol
  ACTIONS DELETE on hr.employees,
             INSERT on hr.employees,
             UPDATE on hr.employees,
             ALL on hr.departments;
```

The following statement creates unified audit policy `read_dir_pol`, which audits `READ` actions on directory `bfile_dir` (created in "[Creating a Directory: Examples](#)"):

```
CREATE AUDIT POLICY read_dir_pol
  ACTIONS READ ON DIRECTORY bfile_dir;
```

### **Auditing System Actions: Examples**

The following query displays the standard RDBMS system actions that can be audited for the database:

```
SELECT name FROM auditable_system_actions
  WHERE component = 'Standard'
    ORDER BY name;
```

NAME
-----
ADMINISTER KEY MANAGEMENT
ALL
ALTER ASSEMBLY
ALTER AUDIT POLICY
ALTER CLUSTER
...

The following statement creates unified audit policy `security_pol`, which audits the system action `ADMINISTER KEY MANAGEMENT`:

```
CREATE AUDIT POLICY security_pol
  ACTIONS ADMINISTER KEY MANAGEMENT;
```

The following statement creates unified audit policy `dir_pol`, which audits all read, write, and execute operations on any directory:

```
CREATE AUDIT POLICY dir_pol
  ACTIONS READ DIRECTORY, WRITE DIRECTORY, EXECUTE DIRECTORY;
```

The following statement creates unified audit policy `all_actions_pol`, which audits all standard RDBMS system actions for the database:

```
CREATE AUDIT POLICY all_actions_pol
  ACTIONS ALL;
```

### **Auditing Component Actions: Example**

The following query displays the actions that can be audited for Oracle Data Pump:

```
SELECT name FROM auditable_system_actions
  WHERE component = 'Datapump';
```

NAME
-----
EXPORT
IMPORT
ALL

The following statement creates unified audit policy `dp_actions_pol`, which audits IMPORT actions for Oracle Data Pump:

```
CREATE AUDIT POLICY dp_actions_pol
    ACTIONS COMPONENT = datapump IMPORT;
```

### Auditing Roles: Example

The following statement creates unified audit policy `java_pol`, which audits the predefined roles `java_admin` and `java_deploy`:

```
CREATE AUDIT POLICY java_pol
    ROLES java_admin, java_deploy;
```

### Auditing System Privileges, Actions, and Roles: Example

The following statement creates unified audit policy `hr_admin_pol`, which audits multiple system privileges, actions, and roles:

```
CREATE AUDIT POLICY hr_admin_pol
    PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
    ACTIONS DELETE on hr.employees,
        INSERT on hr.employees,
        UPDATE on hr.employees,
        ALL on hr.departments,
        LOCK TABLE
    ROLES audit_admin, audit_viewer;
```

### Controlling When a Unified Audit Policy is Enforced: Examples

The following statement creates unified audit policy `order_updates_pol`, which audits UPDATE actions on table `oe.orders`. This policy is enforced only when the auditable statement is issued by an external user. The audit condition is checked once per session.

```
CREATE AUDIT POLICY order_updates_pol
    ACTIONS UPDATE ON oe.orders
    WHEN 'SYS_CONTEXT(''USERENV'', ''IDENTIFICATION_TYPE'') = ''EXTERNAL''
    EVALUATE PER SESSION;
```

The following statement creates unified audit policy `emp_updates_pol`, which audits DELETE, INSERT, and UPDATE actions on table `hr.employees`. This policy is enforced only when the auditable statement is issued by a user who does not have a UID of 100, 105, or 107. The audit condition is checked for each auditable statement.

```
CREATE AUDIT POLICY emp_updates_pol
    ACTIONS DELETE on hr.employees,
        INSERT on hr.employees,
        UPDATE on hr.employees
    WHEN 'UID NOT IN (100, 105, 107)'
    EVALUATE PER STATEMENT;
```

### Creating a Local Unified Audit Policy: Example

The following statement creates local unified audit policy `local_table_pol`, which audits the system privileges `CREATE ANY TABLE` and `DROP ANY TABLE` in the current container:

```
CREATE AUDIT POLICY local_table_pol
    PRIVILEGES CREATE ANY TABLE, DROP ANY TABLE
    CONTAINER = CURRENT;
```

### Creating a Common Unified Audit Policy: Example

The following statement creates common unified audit policy `common_role1_pol`, which audits the common role `c##role1` (created in CREATE ROLE "Examples") across the entire CDB:

```
CREATE AUDIT POLICY c##common_role1_pol
  ROLES c##role1
  CONTAINER = ALL;
```

### Creating an Audit Policy on Columns: Example

The audit policy `pol` generates an audit record when granting privileges on the column `job` in the `emp` table.

```
CREATE AUDIT POLICY pol ACTIONS GRANT(job) on scott.emp;
```

The audit policy `pol` generates an audit record when a new department number is inserted into the `dept` table.

```
CREATE AUDIT POLICY pol ACTIONS INSERT(deptno) on scott.dept;
```

## CREATE CLUSTER

### Purpose

Use the `CREATE CLUSTER` statement to create a cluster. A **cluster** is a schema object that contains data from one or more tables.

- An **indexed cluster** must contain more than one table, and all of the tables in the cluster have one or more columns in common. Oracle Database stores together all the rows from all the tables that share the same cluster key.
- In a **hash cluster**, which can contain one or more tables, Oracle Database stores together rows that have the same hash key value.

For information on existing clusters, query the `USER_CLUSTERS`, `ALL_CLUSTERS`, and `DBA_CLUSTERS` data dictionary views.

### See Also:

- *Oracle Database Concepts* for general information on clusters
- *Oracle Database SQL Tuning Guide* for suggestions on when to use clusters
- *Oracle Database Reference* for information on the data dictionary views

### Prerequisites

To create a cluster in your own schema, you must have `CREATE CLUSTER` system privilege. To create a cluster in another user's schema, you must have `CREATE ANY CLUSTER` system privilege. Also, the owner of the schema to contain the cluster must have either space quota on the tablespace containing the cluster or the `UNLIMITED TABLESPACE` system privilege.

Oracle Database does not automatically create an index for a cluster when the cluster is initially created. Data manipulation language (DML) statements cannot be issued against cluster tables in an indexed cluster until you create a cluster index with a `CREATE INDEX` statement.

## Syntax

`create_cluster ::=`

(`physical_attributes_clause ::=, size_clause ::=, cluster_range_partitions ::=`)

`physical_attributes_clause ::=`

(`storage_clause ::=`)

**parallel\_clause ::=**

**cluster\_range\_partitions ::=**

(*range\_values\_clause ::=*, *table\_partition\_description ::=*)

### Semantics

#### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the cluster does not exist, a new cluster is created at the end of the statement.
- If the cluster exists, this is the cluster you have at the end of the statement. A new one is not created because the older cluster is detected.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

#### schema

Specify the schema to contain the cluster. If you omit `schema`, then Oracle Database creates the cluster in your current schema.

#### cluster

Specify is the name of the cluster to be created. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)".

After you create a cluster, you add tables to it. A cluster can contain a maximum of 32 tables. Object tables and tables containing LOB columns or columns of the Any\* Oracle-supplied types cannot be part of a cluster. After you create a cluster and add tables to it, the cluster is transparent. You can access clustered tables with SQL statements just as you can access nonclustered tables.

 **See Also:**

[CREATE TABLE](#) for information on adding tables to a cluster, "[Creating a Cluster: Example](#)", and "[Adding Tables to a Cluster: Example](#)"

## SHARING

Use the sharing clause if you want to create the cluster in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- METADATA - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- NONE - The object is not shared and can only be accessed in the application root.

### *column*

Specify one or more names of columns in the cluster key. You can specify up to 16 cluster key columns. These columns must correspond in both data type and size to columns in each of the clustered tables, although they need not correspond in name.

You cannot specify integrity constraints as part of the definition of a cluster key column. Instead, you can associate integrity constraints with the tables that belong to the cluster.

 **See Also:**

["Cluster Keys: Example"](#)

### *datatype*

Specify the data type of each cluster key column.

#### Restrictions on Cluster Data Types

Cluster data types are subject to the following restrictions:

- You cannot specify a cluster key column of data type LONG, LONG RAW, REF, nested table, varray, BLOB, CLOB, BFILE, the Any\* Oracle-supplied types, or user-defined object type.
- You can specify a column of type ROWID, but Oracle Database does not guarantee that the values in such columns are valid rowids.

 **See Also:**

["Data Types "](#) for information on data types

## COLLATE

Use this clause to specify the data-bound collation for character data type columns in the cluster key.

For `column_collation_name`, specify the collation as follows:

- When creating an indexed cluster or a sorted hash cluster, you can specify one of the following collations: BINARY, USING\_NLS\_COMP, USING\_NLS\_SORT, or USING\_NLS\_SORT\_CS.
- When creating a hash cluster that is not sorted, you can specify any valid named collation or pseudo-collation.

If you omit this clause, then columns in the cluster key inherit the effective schema default collation of the schema containing the cluster. Refer to the `DEFAULT_COLLATION` clause of `ALTER SESSION` for more information on the effective schema default collation.

The collations of cluster key columns must match the collations of the corresponding columns in the tables created in the cluster.

You can specify the `COLLATE` clause only if the `COMPATIBLE` initialization parameter is set to 12.2 or greater, and the `MAX_STRING_SIZE` initialization parameter is set to EXTENDED.

To change the collation of a cluster key column, you must recreate the cluster.

## SORT

The `SORT` keyword is valid only if you are creating a hash cluster. Table rows are hashed into buckets on cluster key columns without `SORT`, and then sorted in each bucket on the columns with this clause. This may improve response time during subsequent queries on the clustered data.

All columns without the `SORT` clause must come before all columns with the `SORT` clause in the `CREATE CLUSTER` statement.

### Restriction on Sorted Hash Clusters

Row dependency is not supported for sorted hash clusters.

#### See Also:

- See "HASHKEYS Clause" for information on creating a hash cluster.
- *Managing Hash Clusters* for more information.

## `physical_attributes_clause`

The `physical_attributes_clause` lets you specify the storage characteristics of the cluster. Each table in the cluster uses these storage characteristics as well. If you do not specify values for these parameters, then Oracle Database uses the following defaults:

- `PCTFREE: 10`

- PCTUSED: 40
- INITTRANS: 2 or the default value of the tablespace to contain the cluster, whichever is greater

#### See Also:

[physical\\_attributes\\_clause](#) and [storage\\_clause](#) for a complete description of these clauses

### SIZE

Specify the amount of space in bytes reserved to store all rows with the same cluster key value or the same hash value. This space determines the maximum number of cluster or hash values stored in a data block. If SIZE is not a divisor of the data block size, then Oracle Database uses the next largest divisor. If SIZE is larger than the data block size, then the database uses the operating system block size, reserving at least one data block for each cluster or hash value.

The database also considers the length of the cluster key when determining how much space to reserve for the rows having a cluster key value. Larger cluster keys require larger sizes. To see the actual size, query the KEY\_SIZE column of the `USER_CLUSTERS` data dictionary view. (This value does not apply to hash clusters, because hash values are not actually stored in the cluster.)

If you omit this parameter, then the database reserves one data block for each cluster key value or hash value.

### TABLESPACE

Specify the tablespace in which the cluster is to be created.

#### INDEX Clause

Specify INDEX to create an **indexed cluster**. In an indexed cluster, Oracle Database stores together rows having the same cluster key value. Each distinct cluster key value is stored only once in each data block, regardless of the number of tables and rows in which it occurs. If you specify neither INDEX nor HASHKEYS, then Oracle Database creates an indexed cluster by default.

After you create an indexed cluster, you must create an index on the cluster key before you can issue any data manipulation language (DML) statements against a table in the cluster. This index is called the **cluster index**.

You cannot create a cluster index for a hash cluster, and you need not create an index on a hash cluster key.

#### See Also:

[CREATE INDEX](#) for information on creating a cluster index and *Oracle Database Concepts* for general information in indexed clusters

### HASHKEYS Clause

Specify the `HASHKEYS` clause to create a **hash cluster** and specify the number of hash values for the hash cluster. In a hash cluster, Oracle Database stores together rows that have the same hash key value. The hash value for a row is the value returned by the hash function of the cluster.

Oracle Database rounds up the `HASHKEYS` value to the nearest prime number to obtain the actual number of hash values. The minimum value for this parameter is 2. If you omit both the `INDEX` clause and the `HASHKEYS` parameter, then the database creates an indexed cluster by default.

When you create a hash cluster, the database immediately allocates space for the cluster based on the values of the `SIZE` and `HASHKEYS` parameters.

 **See Also:**

[Oracle Database Concepts](#) for more information on how Oracle Database allocates space for clusters and "[Hash Clusters: Examples](#)"

### SINGLE TABLE

`SINGLE TABLE` indicates that the cluster is a type of hash cluster containing only one table. This clause can provide faster access to rows in the table.

#### Restriction on Single-table Clusters

Only one table can be present in the cluster at a time. However, you can drop the table and create a different table in the same cluster.

 **See Also:**

["Single-Table Hash Clusters: Example"](#)

### HASH IS *expr*

Specify an expression to be used as the hash function for the hash cluster. The expression:

- Must evaluate to a positive value
- Must contain at least one column, with referenced columns of any data type as long as the entire expression evaluates to a number of scale 0. For example:  
`number_column * LENGTH(varchar2_column)`
- Cannot reference user-defined PL/SQL functions
- Cannot reference the pseudocolumns `LEVEL` or `ROWNUM`
- Cannot reference the user-related functions `USERENV`, `UID`, or `USER` or the datetime functions `CURRENT_DATE`, `CURRENT_TIMESTAMP`, `DBTIMEZONE`, `EXTRACT(datetime)`, `FROM_TZ`, `LOCALTIMESTAMP`, `NUMTODSINTERVAL`, `NUMTOYMININTERVAL`, `SESSIONTIMEZONE`,

SYSDATE, SYSTIMESTAMP, TO\_DSINTERVAL, TO\_TIMESTAMP, TO\_DATE, TO\_TIMESTAMP\_TZ, TO\_YMINTERVAL, and TZ\_OFFSET.

- Cannot evaluate to a constant
- Cannot be a scalar subquery expression
- Cannot contain columns qualified with a schema or object name (other than the cluster name)

If you omit the `HASH IS` clause, then Oracle Database uses an internal hash function for the hash cluster.

For information on existing hash functions, query the `USER_`, `ALL_`, and `DBA_CLUSTER_HASH_EXPRESSIONS` data dictionary tables.

The cluster key of a hash column can have one or more columns of any data type. Hash clusters with composite cluster keys or cluster keys made up of noninteger columns must use the internal hash function.

#### See Also:

*Oracle Database Reference* for information on the data dictionary views

### ***parallel\_clause***

The `parallel_clause` lets you parallelize the creation of the cluster.

For complete information on this clause, refer to [parallel\\_clause](#) in the documentation on CREATE TABLE.

### **NOROWDEPENDENCIES | ROWDEPENDENCIES**

This clause has the same behavior for a cluster that it has for a table. Refer to "[NOROWDEPENDENCIES | ROWDEPENDENCIES](#)" in CREATE TABLE for information.

### **CACHE | NOCACHE**

#### **CACHE**

Specify `CACHE` if you want the blocks retrieved for this cluster to be placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This clause is useful for small lookup tables.

#### **NOCACHE**

Specify `NOCACHE` if you want the blocks retrieved for this cluster to be placed at the least recently used end of the LRU list in the buffer cache when a full table scan is performed. This is the default behavior.

`NOCACHE` has no effect on clusters for which you specify `KEEP` in the `storage_clause`.

### ***cluster\_range\_partitions***

Specify the `cluster_range_partitions` clause to create a range-partitioned hash cluster. If you specify this clause, then you must also specify the `HASHKEYS` clause.

Use the `cluster_range_partitions` clause to partition the cluster on ranges of values from the column list. When you add a table to a range-partitioned hash cluster, it is automatically partitioned on the same columns, with the same number of partitions, and on the same partition bounds as the cluster. Oracle Database assigns system-generated names to the table partitions.

Each partitioning key column with a character data type must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.

The `cluster_range_partitions` clause has the same semantics as the `range_partitions` clause of `CREATE TABLE`, except that here you cannot specify the `INTERVAL` clause. For complete information, refer to [range\\_partitions](#) in the documentation on `CREATE TABLE`.

#### See Also:

["Range-Partitioned Hash Clusters: Example"](#)

## Examples

### Creating a Cluster: Example

The following statement creates a cluster named `personnel` with the cluster key column `department`, a cluster size of 512 bytes, and storage parameter values:

```
CREATE CLUSTER personnel
  (department NUMBER(4))
SIZE 512
STORAGE (initial 100K next 50K);
```

### Cluster Keys: Example

The following statement creates the cluster index on the cluster key of `personnel`:

```
CREATE INDEX idx_personnel ON CLUSTER personnel;
```

After creating the cluster index, you can add tables to the index and perform DML operations on those tables.

### Adding Tables to a Cluster: Example

The following statements create some departmental tables from the sample `hr.employees` table and add them to the `personnel` cluster created in the earlier example:

```
CREATE TABLE dept_10
  CLUSTER personnel (department_id)
  AS SELECT * FROM employees WHERE department_id = 10;

CREATE TABLE dept_20
  CLUSTER personnel (department_id)
  AS SELECT * FROM employees WHERE department_id = 20;
```

## Hash Clusters: Examples

The following statement creates a hash cluster named language with the cluster key column cust\_language, a maximum of 10 hash key values, each of which is allocated 512 bytes, and storage parameter values:

```
CREATE CLUSTER language (cust_language VARCHAR2(3))
  SIZE 512 HASHKEYS 10
  STORAGE (INITIAL 100k next 50k);
```

Because the preceding statement omits the HASH IS clause, Oracle Database uses the internal hash function for the cluster.

The following statement creates a hash cluster named address with the cluster key made up of the columns postal\_code and country\_id, and uses a SQL expression containing these columns for the hash function:

```
CREATE CLUSTER address
  (postal_code NUMBER, country_id CHAR(2))
  HASHKEYS 20
  HASH IS MOD(postal_code + country_id, 101);
```

### Single-Table Hash Clusters: Example

The following statement creates a single-table hash cluster named cust\_orders with the cluster key customer\_id and a maximum of 100 hash key values, each of which is allocated 512 bytes:

```
CREATE CLUSTER cust_orders (customer_id NUMBER(6))
  SIZE 512 SINGLE TABLE HASHKEYS 100;
```

### Range-Partitioned Hash Clusters: Example

The following statement creates a range-partitioned hash cluster named sales with five range partitions based on the amount sold. The cluster key is made up of the columns amount\_sold and prod\_id. The cluster uses the hash function (amount\_sold \* 10 + prod\_id) and has a maximum of 100000 hash key values, each of which is allocated 300 bytes.

```
CREATE CLUSTER sales (amount_sold NUMBER, prod_id NUMBER)
  HASHKEYS 100000
  HASH IS (amount_sold * 10 + prod_id)
  SIZE 300
  TABLESPACE example
  PARTITION BY RANGE (amount_sold)
    (PARTITION p1 VALUES LESS THAN (2001),
     PARTITION p2 VALUES LESS THAN (4001),
     PARTITION p3 VALUES LESS THAN (6001),
     PARTITION p4 VALUES LESS THAN (8001),
     PARTITION p5 VALUES LESS THAN (MAXVALUE));
```

### Create Cluster Tables: Example

The following statement creates a cluster named emp\_dept with the default key size (600):

```
CREATE CLUSTER emp_dept (deptno NUMBER(3))
  SIZE 600
  TABLESPACE USERS
  STORAGE (INITIAL 200K
    NEXT 300K
    MINEXTENTS 2
    PCTINCREASE 33);
```

The following statement creates a cluster table named dept under emp\_dept cluster:

```
CREATE TABLE dept (
    deptno NUMBER(3) PRIMARY KEY)
CLUSTER emp_dept (deptno);
```

The following statement creates another cluster table named empl under emp\_dept cluster:

```
CREATE TABLE empl (
    empno NUMBER(5) PRIMARY KEY,
    emplname VARCHAR2(15) NOT NULL,
    deptno NUMBER(3) REFERENCES dept)
CLUSTER emp_dept (deptno);
```

The following statement creates an index for the emp\_dept cluster:

```
CREATE INDEX emp_dept_index
ON CLUSTER emp_dept
TABLESPACE USERS
STORAGE (INITIAL 50K
NEXT 50K
MINEXTENTS 2
MAXEXTENTS 10
PCTINCREASE 33);
```

The following statement queries USER\_CLUSTERS to display the cluster metadata:

```
SELECT CLUSTER_NAME, TABLESPACE_NAME, CLUSTER_TYPE, PCT_INCREASE,
MIN_EXTENTS, MAX_EXTENTS FROM USER_CLUSTERS;
CLUSTER_NAME      TABLESPACE CLUST PCT_INCREASE MIN_EXTENTS MAX_EXTENTS
-----  -----
EMP_DEPT        USERS          INDEX           1  2147483645
```

The following statement queries USER\_CLU\_COLUMNS to display the cluster metadata:

```
SELECT * FROM USER_CLU_COLUMNS;
CLUSTER_NAME      CLU_COLUMN_NAME      TABLE_NAME TAB_COLUMN_NAME
-----  -----
EMP_DEPT        DEPTNO            DEPT      DEPTNO
EMP_DEPT        DEPTNO            EMPL      DEPTNO
```

The following statement queries USER\_INDEXES to display the index attributes of the emp\_dept cluster:

```
SELECT INDEX_NAME, INDEX_TYPE, PCT_INCREASE, MIN_EXTENTS, MAX_EXTENTS
FROM USER_INDEXES WHERE TABLE_NAME='EMP_DEPT';
INDEX_NAME      INDEX_TYPE      PCT_INCREASE MIN_EXTENTS MAX_EXTENTS
```

```
-----  
EMP_DEPT_INDEX    CLUSTER          1  2147483645
```

# CREATE CONTEXT

## Purpose

Use the `CREATE CONTEXT` statement to:

- Create a namespace for a **context** (a set of application-defined attributes that validates and secures an application)
- Associate the namespace with the externally created package that sets the context

You can use the `DBMS_SESSION.SET_CONTEXT` procedure in your designated package to set or reset the attributes of the context.

### See Also:

- *Oracle Database Security Guide* for a discussion of contexts
- *Oracle Database PL/SQL Packages and Types Reference* for information on the `DBMS_SESSION.SET_CONTEXT` procedure

## Prerequisites

To create a context namespace, you must have `CREATE ANY CONTEXT` system privilege.

Note that you cannot use a synonym for a package name in the `CREATE CONTEXT` command.

## Syntax

`create_context::=`

## Semantics

### OR REPLACE

Specify `OR REPLACE` to redefine an existing context namespace using a different package.

### **namespace**

Specify the name of the context namespace to create or modify. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)". Context namespaces are always stored in the schema `SYS`.

#### **See Also:**

"[Database Object Naming Rules](#)" for guidelines on naming a context namespace

### **schema**

Specify the schema owning `package`. If you omit `schema`, then Oracle Database uses the current schema.

### **package**

Specify the PL/SQL package that sets or resets the context attributes under the namespace for a user session.

To provide some design flexibility, Oracle Database does not verify the existence of the schema or the validity of the package at the time you create the context.

## **SHARING**

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- `METADATA` - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- `NONE` - The object is not shared and can only be accessed in the application root.

## **INITIALIZED Clause**

The `INITIALIZED` clause lets you specify an entity other than Oracle Database that can initialize the context namespace.

## **EXTERNALLY**

`EXTERNALLY` indicates that the namespace can be initialized using an OCI interface when establishing a session.

 **See Also:**

*Oracle Call Interface Programmer's Guide* for information on using OCI to establish a session

**GLOBALLY**

**GLOBALLY** indicates that the namespace can be initialized by the LDAP directory when a global user connects to the database.

After the session is established, only the designated PL/SQL package can issue commands to write to any attributes inside the namespace.

 **See Also:**

*Oracle Database Security Guide* for information on establishing globally initialized contexts

**ACCESSED GLOBALLY**

This clause indicates that any application context set in *namespace* is accessible throughout the entire instance. This setting lets multiple sessions share application attributes.

**Examples****Creating an Application Context: Example**

This example uses a PL/SQL package `emp_mgmt`, which validates and secures a human resources application. See *Oracle Database PL/SQL Language Reference* for the example that creates that package. The following statement creates the context namespace `hr_context` and associates it with the package `emp_mgmt`:

```
CREATE CONTEXT hr_context USING emp_mgmt;
```

You can control data access based on this context using the `SYS_CONTEXT` function. For example, the `emp_mgmt` package has defined an attribute `department_id` as a particular department identifier. You can secure the base table `employees` by creating a view that restricts access based on the value of `department_id`, as follows:

```
CREATE VIEW hr_org_secure_view AS
  SELECT * FROM employees
  WHERE department_id = SYS_CONTEXT('hr_context', 'department_id');
```

 **See Also:**

`SYS_CONTEXT` and *Oracle Database Security Guide* for more information on using application contexts to retrieve user information

# CREATE CONTROLFILE

 **Note:**

Oracle recommends that you perform a full backup of all files in the database before using this statement. For more information, see *Oracle Database Backup and Recovery User's Guide*.

## Purpose

The CREATE CONTROLFILE statement should be used in only a few cases. Use this statement to re-create a control file if all control files being used by the database are lost **and** no backup control file exists. You can also use this statement to change the maximum number of redo log file groups, redo log file members, archived redo log files, data files, or instances that can concurrently have the database mounted and open.

To change the name of the database, Oracle recommends that you use the DBNEWID utility rather than the CREATE CONTROLFILE statement. DBNEWID is preferable because no OPEN RESETLOGS operation is required after changing the database name.

 **See Also:**

- *Oracle Database Utilities* for more information about the DBNEWID utility
- ALTER DATABASE "BACKUP CONTROLFILE Clause" for information creating a script based on an existing database control file

## Prerequisites

To create a control file, you must have the SYSDBA or SYSBACKUP system privilege.

The database must not be mounted by any instance. After successfully creating the control file, Oracle mounts the database in the mode specified by the CLUSTER\_DATABASE parameter. The DBA must then perform media recovery before opening the database. If you are using the database with Oracle Real Application Clusters (Oracle RAC), then you must then shut down and remount the database in SHARED mode (by setting the value of the CLUSTER\_DATABASE initialization parameter to TRUE) before other instances can start up.

## Syntax

*create\_controlfile ::=*

(*storage\_clause ::=*)

*logfile\_clause ::=*

(*file\_specification ::=*)

*character\_set\_clause ::=*

## Semantics

When you issue a `CREATE CONTROLFILE` statement, Oracle Database creates a new control file based on the information you specify in the statement. The control file resides in the location specified in the `CONTROL_FILES` initialization parameter. If that parameter does not have a value, then the database creates an Oracle-managed control file in the default control file destination, which is one of the following (in order of precedence):

1. One or more control files as specified in the `DB_CREATE_ONLINE_LOG_DEST_n` initialization parameter. The file in the first directory is the primary control file. When `DB_CREATE_ONLINE_LOG_DEST_n` is specified, the database does not create a control file in `DB_CREATE_FILE_DEST` or in `DB_RECOVERY_FILE_DEST` (the fast recovery area).
2. If no value is specified for `DB_CREATE_ONLINE_LOG_DEST_n`, but values are set for both the `DB_CREATE_FILE_DEST` and `DB_RECOVERY_FILE_DEST`, then the database creates one control file in each location. The location specified in `DB_CREATE_FILE_DEST` is the primary control file.
3. If a value is specified only for `DB_CREATE_FILE_DEST`, then the database creates one control file in that location.
4. If a value is specified only for `DB_RECOVERY_FILE_DEST`, then the database creates one control file in that location.

If no values are set for any of these parameters, then the database creates a control file in the default location for the operating system on which the database is running. This control file is not an Oracle Managed File.

If you omit any clauses, then Oracle Database uses the default values rather than the values for the previous control file. After successfully creating the control file, Oracle Database mounts the database in the mode specified by the initialization parameter `CLUSTER_DATABASE`. If that parameter is not set, then the default value is `FALSE`, and the database is mounted in `EXCLUSIVE` mode. Oracle recommends that you then shut down the instance and take a full backup of all files in the database.

### See Also:

*Oracle Database Backup and Recovery User's Guide*

## REUSE

Specify `REUSE` to indicate that existing control files identified by the initialization parameter `CONTROL_FILES` can be reused, overwriting any information they may currently contain. If you omit this clause and any of these control files already exists, then Oracle Database returns an error.

## DATABASE Clause

Specify the name of the database. The value of this parameter must be the existing database name established by the previous `CREATE DATABASE` statement or `CREATE CONTROLFILE` statement.

## SET DATABASE Clause

Use `SET DATABASE` to change the name of the database. The name of a database can be as long as eight bytes.

When you specify this clause, you must also specify `RESETLOGS`. If you want to rename the database and retain your existing log files, then after issuing this `CREATE CONTROLFILE` statement you must complete a full database recovery using an `ALTER DATABASE RECOVER USING BACKUP CONTROLFILE` statement.

### *logfile\_clause*

Use the `logfile_clause` to specify the redo log files for your database. You must list all members of all redo log file groups.

Use the `redo_log_file_spec` form of `file_specification` (see [file\\_specification](#)) to list regular redo log files in an operating system file system or to list Oracle ASM disk group redo log files. When using a form of `ASM_filename`, you cannot specify the `autoextend_clause` of the `redo_log_file_spec`.

If you specify `RESETLOGS` in this clause, then you must use one of the file creation forms of `ASM_filename`. If you specify `NORESETLOGS`, then you must specify one of the reference forms of `ASM_filename`.

#### See Also:

[ASM\\_filename](#) for information on the different forms of syntax and *Oracle Automatic Storage Management Administrator's Guide* for general information about using Oracle ASM

## GROUP *integer*

Specify the logfile group number. If you specify `GROUP` values, then Oracle Database verifies these values with the `GROUP` values when the database was last open.

If you omit this clause, then the database creates logfiles using system default values. In addition, if either the `DB_CREATE_ONLINE_LOG_DEST_n` or `DB_CREATE_FILE_DEST` initialization parameter has been set, and if you have specified `RESETLOGS`, then the database creates two logs in the default logfile destination specified in the `DB_CREATE_ONLINE_LOG_DEST_n` parameter, and if it is not set, then in the `DB_CREATE_FILE_DEST` parameter.

#### See Also:

[file\\_specification](#) for a full description of this clause

## RESETLOGS

Specify `RESETLOGS` if you want Oracle Database to ignore the contents of the files listed in the `LOGFILE` clause. These files do not have to exist. You must specify this clause if you have specified the `SET DATABASE` clause.

Each *redo\_log\_file\_spec* in the `LOGFILE` clause must specify the `SIZE` parameter. The database assigns all online redo log file groups to thread 1 and enables this thread for public use by any instance. After using this clause, you must open the database using the `RESETLOGS` clause of the `ALTER DATABASE` statement.

### NORESETLOGS

Specify `NORESETLOGS` if you want Oracle Database to use all files in the `LOGFILE` clause as they were when the database was last open. These files must exist and must be the current online redo log files rather than restored backups. The database reassigns the redo log file groups to the threads to which they were previously assigned and reenables the threads as they were previously enabled.

You cannot specify `NORESETLOGS` if you have specified the `SET DATABASE` clause to change the name of the database. Refer to "["SET DATABASE Clause"](#)" for more information.

### DATAFILE Clause

Specify the data files of the database. You must list all data files. These files must all exist, although they may be restored backups that require media recovery.

Do not include in the `DATAFILE` clause any data files in read-only tablespaces. You can add these types of files to the database later. Also, do not include in this clause any temporary data files (temp files).

Use the `datafile_tempfile_spec` form of *file\_specification* (see ["\*file\\_specification\*"\)](#) to list regular data files and temp files in an operating system file system or to list Oracle ASM disk group files. When using a form of `ASM_filename`, you must use one of the reference forms of `ASM_filename`. Refer to ["`ASM\_filename` for information on the different forms of syntax.](#)

#### See Also:

*Oracle Automatic Storage Management Administrator's Guide* for general information about using Oracle ASM

### Restriction on DATAFILE

You cannot specify the `autoextend_clause` of *file\_specification* in this `DATAFILE` clause.

### MAXLOGFILES Clause

Specify the maximum number of online redo log file groups that can ever be created for the database. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The default and maximum values depend on your operating system. The value that you specify should not be less than the greatest `GROUP` value for any redo log file group.

### MAXLOGMEMBERS Clause

Specify the maximum number of members, or identical copies, for a redo log file group. Oracle Database uses this value to determine how much space to allocate in

the control file for the names of redo log files. The minimum value is 1. The maximum and default values depend on your operating system.

#### **MAXLOGHISTORY Clause**

This parameter is useful only if you are using Oracle Database in ARCHIVELOG mode. Specify your current estimate of the maximum number of archived redo log file groups needed for automatic media recovery of the database. The database uses this value to determine how much space to allocate in the control file for the names of archived redo log files.

The minimum value is 0. The default value is a multiple of the MAXINSTANCES value and depends on your operating system. The maximum value is limited only by the maximum size of the control file. The database will continue to add additional space to the appropriate section of the control file as needed, so that you do not need to re-create the control file if your original configuration is no longer adequate. As a result, the actual value of this parameter can eventually exceed the value you specify.

#### **MAXDATAFILES Clause**

Specify the initial sizing of the data files section of the control file at CREATE DATABASE or CREATE CONTROLFILE time. An attempt to add a file whose number is greater than MAXDATAFILES, but less than or equal to DB\_FILES, causes the control file to expand automatically so that the data files section can accommodate more files.

The number of data files accessible to your instance is also limited by the initialization parameter DB\_FILES.

#### **MAXINSTANCES Clause**

Specify the maximum number of instances that can simultaneously have the database mounted and open. This value takes precedence over the value of the initialization parameter INSTANCES. The minimum value is 1. The maximum and default values depend on your operating system.

#### **ARCHIVELOG | NOARCHIVELOG**

Specify ARCHIVELOG to archive the contents of redo log files before reusing them. This clause prepares for the possibility of media recovery as well as instance or system failure recovery.

If you omit both the ARCHIVELOG clause and NOARCHIVELOG clause, then Oracle Database chooses NOARCHIVELOG mode by default. After creating the control file, you can change between ARCHIVELOG mode and NOARCHIVELOG mode with the ALTER DATABASE statement.

#### **FORCE LOGGING**

Use this clause to put the database into FORCE LOGGING mode after control file creation. When the database is in this mode, Oracle Database logs all changes in the database except changes to temporary tablespaces and temporary segments. This setting takes precedence over and is independent of any NOLOGGING or FORCE LOGGING settings you specify for individual tablespaces and any NOLOGGING settings you specify for individual database objects. If you omit this clause, then the database will not be in FORCE LOGGING mode after the control file is created.

 **Note:**

FORCE LOGGING mode can have performance effects. Refer to *Oracle Database Administrator's Guide* for information on when to use this setting.

## SET STANDBY NOLOGGING FOR DATA AVAILABILITY | LOAD PERFORMANCE

### SET STANDBY NOLOGGING

The SET STANDBY NOLOGGING disables logging on the standby. You can specify it in two modes:

- **SET STANDBY NOLOGGING FOR DATA AVAILABILITY** guarantees full data replication to the standby database. The primary and standby databases are synchronized during the load. In cases of network congestion the primary database will throttle its load.
- **SET STANDBY NOLOGGING FOR LOAD PERFORMANCE** to maintain speed of primary database load and synchronize with the standby later.

### Restrictions On SET STANDBY NOLOGGING

The SET STANDBY NOLOGGING clause cannot be used at the same time as FORCE LOGGING.

#### *character\_set\_clause*

If you specify a character set, then Oracle Database reconstructs character set information in the control file. If media recovery of the database is subsequently required, then this information will be available before the database is open, so that tablespace names can be correctly interpreted during recovery. This clause is required only if you are using a character set other than the default, which depends on your operating system. Oracle Database prints the current database character set to the alert log in \$ORACLE\_HOME/log during startup.

If you are re-creating your control file and you are using Recovery Manager for tablespace recovery, and if you specify a different character set from the one stored in the data dictionary, then tablespace recovery will not succeed. However, at database open, the control file character set will be updated with the correct character set from the data dictionary.

You cannot modify the character set of the database with this clause.

 **See Also:**

*Oracle Database Backup and Recovery User's Guide* for more information on tablespace recovery

### Examples

#### Creating a Controlfile: Example

This statement re-creates a control file. In this statement, database `demo` was created with the `WE8DEC` character set. The example uses the word `path` where you would normally insert the path on your system to the appropriate Oracle Database directories.

```
STARTUP NOMOUNT

CREATE CONTROLFILE REUSE DATABASE "demo" NORESETLOGS NOARCHIVELOG
  MAXLOGFILES 32
  MAXLOGMEMBERS 2
  MAXDATAFILES 32
  MAXINSTANCES 1
  MAXLOGHISTORY 449
LOGFILE
  GROUP 1 '/path/oracle/dbs/t_log1.f'  SIZE 500K,
  GROUP 2 '/path/oracle/dbs/t_log2.f'  SIZE 500K
# STANDBY LOGFILE
DATAFILE
  '/path/oracle/dbs/t_db1.f',
  '/path/oracle/dbs/dbu19i.dbf',
  '/path/oracle/dbs/tbs_11.f',
  '/path/oracle/dbs/smundo.dbf',
  '/path/oracle/dbs/demo.dbf'
CHARACTER SET WE8DEC
;
```

## CREATE DATABASE

### Note:

This statement prepares a database for initial use and erases any data currently in the specified files. Use this statement only when you understand its ramifications.

### Note:

In this release of Oracle Database and in subsequent releases, several enhancements are being made to ensure the security of default database user accounts. You can find a security checklist for this release in *Oracle Database Security Guide*. Oracle recommends that you read this checklist and configure your database accordingly.

### Purpose

Use the `CREATE DATABASE` statement to create a database, making it available for general use.

This statement erases all data in any specified data files that already exist in order to prepare them for initial database use. If you use the statement on an existing database, then all data in the data files is lost.

After creating the database, this statement mounts it in either exclusive or parallel mode, depending on the value of the `CLUSTER_DATABASE` initialization parameter and opens it, making it available for normal use. You can then create tablespaces for the database.

 See Also:

- [ALTER DATABASE](#) for information on modifying a database
- *Oracle Database Java Developer's Guide* for information on creating an Oracle Java virtual machine
- [CREATE TABLESPACE](#) for information on creating tablespaces

### Prerequisites

To create a database, you must have the `SYSDBA` system privilege. An initialization parameter file with the name of the database to be created must be available, and you must be in `STARTUP NOMOUNT` mode.

### Syntax

`create_database ::=`

(`database_logging_clauses ::=`, `tablespace_clauses ::=`, `set_time_zone_clause ::=`,  
`datafile_tempfile_spec ::=`, `enable_pluggable_database ::=`)

**database\_logging\_clauses ::=**

**default\_tablespace ::=**

**default\_temp\_tablespace ::=**

(*file\_specification*::=)

***extent\_management\_clause*::=**

(*size\_clause*::=)

***undo\_tablespace*::=**

(*file\_specification*::=)

***set\_time\_zone\_clause*::=**

***enable\_pluggable\_database::=***

(*tablespace\_datafile\_clauses ::=, undo\_mode\_clause ::=*)

***file\_name\_convert ::=***

***tablespace\_datafile\_clauses ::=***

(*size\_clause ::=, autoextend\_clause ::=*)

***undo\_mode\_clause ::=***

## Semantics

### ***database***

Specify the name of the database to be created. The name must match the value of the `DB_NAME` initialization parameter. The name can be up to 8 bytes long and can contain only ASCII characters. The following characters are valid in a database name: alphanumeric characters, underscore (\_), number sign (#), and dollar sign (\$). No other characters are valid. The database name must start with an alphabetic character. Oracle Database writes this name into the control file. If you subsequently issue an `ALTER DATABASE` statement that

explicitly specifies a database name, then Oracle Database verifies that name with the name in the control file.

The database name is case insensitive and is stored in uppercase ASCII characters. If you specify the database name as a quoted identifier, then the quotation marks are silently ignored.

 **Note:**

You cannot use special characters from European or Asian character sets in a database name. For example, characters with umlauts are not allowed.

If you omit the database name from a `CREATE DATABASE` statement, then Oracle Database uses the name specified by the initialization parameter `DB_NAME`. The `DB_NAME` initialization parameter must be set in the database initialization parameter file, and if you specify a different name from the value of that parameter, then the database returns an error. Refer to "[Database Object Naming Rules](#)" for additional rules to which database names should adhere.

#### **USER SYS ..., USER SYSTEM ...**

Use these clauses to establish passwords for the `SYS` and `SYSTEM` users. These clauses are not mandatory in this release. However, if you specify either clause, then you must specify both clauses.

If you do not specify these clauses, then Oracle Database creates the default `password change_on_install` for user `SYS`. You can change this password later with the `ALTER USER` statement.

 **See Also:**

[ALTER USER](#)

#### **CONTROLFILE REUSE Clause**

Specify `CONTROLFILE REUSE` to reuse existing control files identified by the initialization parameter `CONTROL_FILES`, overwriting any information they currently contain. Normally you use this clause only when you are re-creating a database, rather than creating one for the first time. When you create a database for the first time, Oracle Database creates a control file in the default destination, which is dependent on the value of several initialization parameters. See `CREATE CONTROLFILE`, "[Semantics](#)".

You cannot use this clause if you also specify a parameter value that requires that the control file be larger than the existing files. These parameters are `MAXLOGFILES`, `MAXLOGMEMBERS`, `MAXLOGHISTORY`, `MAXDATAFILES`, and `MAXINSTANCES`.

If you omit this clause and any of the files specified by `CONTROL_FILES` already exist, then the database returns an error.

### MAXDATAFILES Clause

Specify the initial sizing of the data files section of the control file at CREATE DATABASE or CREATE CONTROLFILE time. An attempt to add a file whose number is greater than MAXDATAFILES, but less than or equal to DB\_FILES, causes the Oracle Database control file to expand automatically so that the data files section can accommodate more files.

The number of data files accessible to your instance is also limited by the initialization parameter DB\_FILES.

### MAXINSTANCES Clause

Specify the maximum number of instances that can simultaneously have this database mounted and open. This value takes precedence over the value of initialization parameter INSTANCES. The minimum value is 1. The maximum value is 1055. The default depends on your operating system.

### CHARACTER SET Clause

Specify the character set the database uses to store data. The supported character sets and default value of this parameter depend on your operating system.

#### Restriction on CHARACTER SET

You cannot specify the AL16UTF16 character set as the database character set.

 **See Also:**

*Oracle Database Globalization Support Guide* for more information about choosing a character set

### NATIONAL CHARACTER SET Clause

Specify the national character set used to store data in columns specifically defined as NCHAR, NCLOB, or NVARCHAR2. Valid values are AL16UTF16 and UTF8. The default is AL16UTF16.

 **See Also:**

*Oracle Database Globalization Support Guide* for information on Unicode data type support

### SET DEFAULT TABLESPACE Clause

Use this clause to determine the default type of subsequently created tablespaces and of the SYSTEM and SYSAUX tablespaces. Specify either BIGFILE or SMALLFILE to set the default type of subsequently created tablespaces as a bigfile or smallfile tablespace, respectively.

- A **bigfile tablespace** contains only one data file or temp file, which can contain up to approximately 4 billion ( $2^{32}$ ) blocks. The maximum size of the single data file or temp file is 128 terabytes (TB) for a tablespace with 32K blocks and 32TB for a tablespace with 8K blocks.

- A **smallfile tablespace** is a traditional Oracle tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million ( $2^{22}$ ) blocks.

If you omit this clause, then Oracle Database creates smallfile tablespaces by default.

 **See Also:**

- *Oracle Database Administrator's Guide* for more information about bigfile tablespaces
- "[Setting the Default Type of Tablespaces: Example](#)" for an example using this syntax

#### ***database\_logging\_clauses***

Use the *database\_logging\_clauses* to determine how Oracle Database will handle redo log files for this database.

#### **LOGFILE Clause**

Specify one or more files to be used as redo log files. Use the *redo\_log\_file\_spec* form of *file\_specification* to create regular redo log files in an operating system file system or to create Oracle ASM disk group redo log files. When using a form of *ASM\_filename*, you cannot specify the *autoextend\_clause* of *redo\_log\_file\_spec*.

The *redo\_log\_file\_spec* clause specifies a redo log file group containing one or more redo log file members (copies). All redo log files specified in a `CREATE DATABASE` statement are added to redo log thread number 1.

 **See Also:**

[\*file\\_specification\*](#) for a full description of this clause

If you omit the `LOGFILE` clause, then Oracle Database creates an Oracle-managed log file member in the default destination, which is one of the following locations (in order of precedence):

- If `DB_CREATE_ONLINE_LOG_DEST_n` is set, then the database creates a log file member in each directory specified, up to the value of the `MAXLOGMEMBERS` initialization parameter.
- If the `DB_CREATE_ONLINE_LOG_DEST_n` parameter is not set, but both the `DB_CREATE_FILE_DEST` and `DB_RECOVERY_FILE_DEST` initialization parameters are set, then the database creates one Oracle-managed log file member in each of those locations. The log file in the `DB_CREATE_FILE_DEST` destination is the first member.
- If only the `DB_CREATE_FILE_DEST` initialization parameter is specified, then Oracle Database creates a log file member in that location.
- If only the `DB_RECOVERY_FILE_DEST` initialization parameter is specified, then Oracle Database creates a log file member in that location.

In all these cases, the parameter settings must correctly specify operating system filenames or creation form Oracle ASM filenames, as appropriate.

If no values are set for any of these parameters, then the database creates a log file in the default location for the operating system on which the database is running. This log file is not an Oracle Managed File.

#### **GROUP *integer***

Specify the number that identifies the redo log file group. The value of *integer* can range from 1 to the value of the `MAXLOGFILES` parameter. A database must have at least two redo log file groups. You cannot specify multiple redo log file groups having the same `GROUP` value. If you omit this parameter, then Oracle Database generates its value automatically. You can examine the `GROUP` value for a redo log file group through the dynamic performance view `V$LOG`.

#### **MAXLOGFILES Clause**

Specify the maximum number of redo log file groups that can ever be created for the database. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The default, minimum, and maximum values depend on your operating system.

#### **MAXLOGMEMBERS Clause**

Specify the maximum number of members, or copies, for a redo log file group. Oracle Database uses this value to determine how much space to allocate in the control file for the names of redo log files. The minimum value is 1. The maximum and default values depend on your operating system.

#### **MAXLOGHISTORY Clause**

This parameter is useful only if you are using Oracle Database in `ARCHIVELOG` mode with Oracle Real Application Clusters (Oracle RAC). Specify the maximum number of archived redo log files for automatic media recovery of Oracle RAC. The database uses this value to determine how much space to allocate in the control file for the names of archived redo log files. The minimum value is 0. The default value is a multiple of the `MAXINSTANCES` value and depends on your operating system. The maximum value is limited only by the maximum size of the control file.

#### **ARCHIVELOG**

Specify `ARCHIVELOG` if you want the contents of a redo log file group to be archived before the group can be reused. This clause prepares for the possibility of media recovery.

#### **NOARCHIVELOG**

Specify `NOARCHIVELOG` if the contents of a redo log file group need not be archived before the group can be reused. This clause does not allow for the possibility of media recovery.

The default is `NOARCHIVELOG` mode. After creating the database, you can change between `ARCHIVELOG` mode and `NOARCHIVELOG` mode with the `ALTER DATABASE` statement.

#### **FORCE LOGGING**

Use this clause to put the database into `FORCE LOGGING` mode. Oracle Database will log all changes in the database except for changes in temporary tablespaces and temporary segments. This setting takes precedence over and is independent of any `NOLOGGING` or `FORCE`

LOGGING settings you specify for individual tablespaces and any NOLOGGING settings you specify for individual database objects.

FORCE LOGGING mode is persistent across instances of the database. If you shut down and restart the database, then the database is still in FORCE LOGGING mode. However, if you re-create the control file, then Oracle Database will take the database out of FORCE LOGGING mode unless you specify FORCE LOGGING in the CREATE CONTROLFILE statement.

 **Note:**

FORCE LOGGING mode can have performance effects. Refer to *Oracle Database Administrator's Guide* for information on when to use this setting.

 **See Also:**

[CREATE CONTROLFILE](#)

## SET STANDBY NOLOGGING FOR DATA AVAILABILITY | LOAD PERFORMANCE

The SET STANDBY NOLOGGING disables logging on the standby. You can specify it in two modes:

- **SET STANDBY NOLOGGING FOR DATA AVAILABILITY** guarantees full data replication to the standby database. The primary and standby databases are synchronized during the load. In cases of network congestion the primary database will throttle its load.
- **SET STANDBY NOLOGGING FOR LOAD PERFORMANCE** to maintain speed of primary database load and synchronize with the standby later.

### Restrictions SET STANDBY NOLOGGING

The SET STANDBY NOLOGGING clause cannot be used at the same time as FORCE LOGGING.

#### ***tablespace\_clauses***

Use the tablespace clauses to configure the SYSTEM and SYSAUX tablespaces and to specify a default temporary tablespace and an undo tablespace.

#### ***extent\_management\_clause***

Use this clause to create a locally managed SYSTEM tablespace. If you omit this clause, then the SYSTEM tablespace will be dictionary managed.

 **Note:**

When you create a locally managed `SYSTEM` tablespace, you cannot change it to be dictionary managed, nor can you create any other dictionary-managed tablespaces in this database.

If you specify this clause, then the database must have a default temporary tablespace, because a locally managed `SYSTEM` tablespace cannot store temporary segments.

- If you specify `EXTENT MANAGEMENT LOCAL` but you do not specify the `DATAFILE` clause, then you can omit the `default_temp_tablespace` clause. Oracle Database will create a default temporary tablespace called `TEMP` with one data file of size 10M with autoextend disabled.
- If you specify both `EXTENT MANAGEMENT LOCAL` and the `DATAFILE` clause, then you must also specify the `default_temp_tablespace` clause and explicitly specify a temp file for that temporary tablespace.

If you have opened the instance in automatic undo mode, similar requirements exist for the database undo tablespace:

- If you specify `EXTENT MANAGEMENT LOCAL` but you do not specify the `DATAFILE` clause, then you can omit the `undo_tablespace` clause. Oracle Database will create an undo tablespace named `SYS_UNDOTBS`.
- If you specify both `EXTENT MANAGEMENT LOCAL` and the `DATAFILE` clause, then you must also specify the `undo_tablespace` clause and explicitly specify a data file for that tablespace.

 **See Also:**

*Oracle Database Administrator's Guide* for more information on locally managed and dictionary-managed tablespaces

### **DATAFILE Clause**

Specify one or more files to be used as data files. All these files become part of the `SYSTEM` tablespace. Use the data `file_tempfile_spec` form of `file_specification` to create regular data files and temp files in an operating system file system or to create Oracle ASM disk group files.

 **Note:**

This clause is optional, as is the `DATAFILE` clause of the `undo_tablespace` clause. Therefore, to avoid ambiguity, if your intention is to specify a data file for the `SYSTEM` tablespace with this clause, then do *not* specify it immediately after an `undo_tablespace` clause that does not include the optional `DATAFILE` clause. If you do so, then Oracle Database will interpret the `DATAFILE` clause to be part of the `undo_tablespace` clause.

The syntax for specifying data files for the `SYSTEM` tablespace is the same as that for specifying data files during tablespace creation using the `CREATE TABLESPACE` statement, whether you are storing files using Oracle ASM or in a file system.

 **See Also:**

[CREATE TABLESPACE](#) for information on specifying data files

If you are running the database in automatic undo mode and you specify a data file name for the `SYSTEM` tablespace, then Oracle Database expects to generate data files for all tablespaces. Oracle Database does this automatically if you are using Oracle Managed Files—you have set a value for the `DB_CREATE_FILE_DEST` initialization parameter. However, if you are not using Oracle Managed Files and you specify this clause, then you must also specify the `undo_tablespace` clause and the `default_temp_tablespace` clause.

If you omit this clause, then:

- If the `DB_CREATE_FILE_DEST` initialization parameter is set, then Oracle Database creates a 100 MB Oracle-managed data file with a system-generated name in the default file destination specified in the parameter.
- If the `DB_CREATE_FILE_DEST` initialization parameter is not set, then Oracle Database creates one data file whose name and size depend on your operating system.

 **See Also:**

[file\\_specification](#) for syntax

### SYSAUX Clause

Oracle Database creates both the `SYSTEM` and `SYSAUX` tablespaces as part of every database. Use this clause if you are not using Oracle Managed Files and you want to specify one or more data files for the `SYSAUX` tablespace.

You must specify this clause if you have specified one or more data files for the `SYSTEM` tablespace using the `DATAFILE` clause. If you are using Oracle Managed Files and you omit this clause, then the database creates the `SYSAUX` data files in the default location set up for Oracle Managed Files.

If you have enabled Oracle Managed Files and you omit the `SYSAUX` clause, then the database creates the `SYSAUX` tablespace as an online, permanent, locally managed tablespace with one data file of 100 MB, with logging enabled and automatic segment-space management.

The syntax for specifying data files for the `SYSAUX` tablespace is the same as that for specifying data files during tablespace creation using the `CREATE TABLESPACE` statement, whether you are storing files using Oracle ASM or in a file system.

 See Also:

- [CREATE TABLESPACE](#) for information on creating the `SYSAUX` tablespace during database upgrade and for information on specifying data files in a tablespace
- [Oracle Database Administrator's Guide](#) for more information on creating the `SYSAUX` tablespace

**`default_tablespace`**

Specify this clause to create a default permanent tablespace for the database. Oracle Database creates a smallfile tablespace and subsequently will assign to this tablespace any non-`SYSTEM` users for whom you do not specify a different permanent tablespace. If you do not specify this clause, then the `SYSTEM` tablespace is the default permanent tablespace for non-`SYSTEM` users.

The `DATAFILE` clause and `extent_management_clause` have the same semantics they have in a `CREATE TABLESPACE` statement. Refer to "["DATAFILE | TEMPFILE Clause"](#)" and ["extent\\_management\\_clause"](#) for information on these clauses.

**`default_temp_tablespace`**

Use this clause to create a default shared temporary tablespace or a default local temporary tablespace. Oracle Database will assign to these temporary tablespaces any users for whom you do not specify different temporary tablespaces.

- Specify `DEFAULT TEMPORARY TABLESPACE` to create a default shared temporary tablespace for the database. Shared temporary tablespaces were available in prior releases of Oracle Database and were called "temporary tablespaces." Elsewhere in this guide, the term "temporary tablespace" refers to a shared temporary tablespace unless specified otherwise. If you do not specify this clause, and if the database does not create a default shared temporary tablespace automatically in the process of creating a locally managed `SYSTEM` tablespace, then the `SYSTEM` tablespace is the default shared temporary tablespace.
- Starting with Oracle Database 12c Release 2 (12.2), you can specify `DEFAULT LOCAL TEMPORARY TABLESPACE` to create a default local temporary tablespace. Local temporary tablespaces are useful for Oracle Real Application Clusters and Oracle Flex Clusters. They store a separate, nonshared temp file for each database instance, which can improve I/O performance. A local temporary tablespace must be a `BIGFILE` tablespace.
  - Specify `FOR ALL` to instruct the database to create separate, nonshared temp files for all HUB and LEAF nodes.
  - Specify `FOR LEAF` to instruct the database to create separate nonshared temp files for only LEAF nodes. If you specify this clause, then HUB nodes will use the default shared temporary tablespace. For SQL operations that span both HUB and LEAF nodes, HUB nodes will use the default shared temporary tablespace and LEAF nodes will use the default local temporary tablespace.

If you do not create a local temporary tablespace, then HUB and LEAF nodes will use the default shared temporary tablespace.

Specify BIGFILE or SMALLFILE to determine whether the default temporary tablespace is a bigfile or smallfile tablespace. These clauses have the same semantics as in the "SET DEFAULT TABLESPACE Clause".

The TEMPFILE clause part of this clause is optional if you have enabled Oracle Managed Files by setting the DB\_CREATE\_FILE\_DEST initialization parameter. If you have not specified a value for this parameter, then the TEMPFILE clause is required. If you have specified BIGFILE, then you can specify only one temp file in this clause.

The syntax for specifying temp files for the default temporary tablespace is the same as that for specifying temp files during temporary tablespace creation using the CREATE TABLESPACE statement, whether you are storing files using Oracle ASM or in a file system.

The extent\_management\_clause clause has the same semantics in CREATE DATABASE and CREATE TABLESPACE statements. For complete information, refer to the CREATE TABLESPACE ... extent\_management\_clause .

#### See Also:

[CREATE TABLESPACE](#) for information on specifying temp files

#### Note:

On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.

### Restrictions on Default Temporary Tablespaces

Default temporary tablespaces are subject to the following restrictions:

- You cannot specify the SYSTEM tablespace in this clause.
- The default temporary tablespace must have a standard block size.

#### *undo\_tablespace*

If you have opened the instance in automatic undo mode (the UNDO MANAGEMENT initialization parameter is set to AUTO, which is the default), then you can specify the *undo\_tablespace* to create a tablespace to be used for undo data. Oracle strongly recommends that you use automatic undo mode. However, if you want undo space management to be handled by way of rollback segments, then you must omit this clause. You can also omit this clause if you have set a value for the UNDO\_TABLESPACE

initialization parameter. If that parameter has been set, and if you specify this clause, then `tablespace` must be the same as that parameter value.

- Specify `BIGFILE` if you want the undo tablespace to be a bigfile tablespace. A **bigfile tablespace** contains only one data file, which can be up to 8 exabytes (8 million terabytes) in size.
- Specify `SMALLFILE` if you want the undo tablespace to be a smallfile tablespace. A **smallfile tablespace** is a traditional Oracle Database tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million ( $2^{22}$ ) blocks.
- The `DATAFILE` clause part of this clause is optional if you have enabled Oracle Managed Files by setting the `DB_CREATE_FILE_DEST` initialization parameter. If you have not specified a value for this parameter, then the `DATAFILE` clause is required. If you have specified `BIGFILE`, then you can specify only one data file in this clause.

The syntax for specifying data files for the undo tablespace is the same as that for specifying data files during tablespace creation using the `CREATE TABLESPACE` statement, whether you are storing files using Oracle ASM or in a file system.

 **See Also:**

[CREATE TABLESPACE](#) for information on specifying data files

If you specify this clause, then Oracle Database creates an undo tablespace named `tablespace`, creates the specified data file(s) as part of the undo tablespace, and assigns this tablespace as the undo tablespace of the instance. Oracle Database will manage undo data using this undo tablespace. The `DATAFILE` clause of this clause has the same behavior as described in "["DATAFILE Clause"](#)".

If you have specified a value for the `UNDO_TABLESPACE` initialization parameter in your initialization parameter file before mounting the database, then you must specify the same name in this clause. If these names differ, then Oracle Database will return an error when you open the database.

If you omit this clause, then Oracle Database creates a default database with a default smallfile undo tablespace named `SYS_UNDOTBS` and assigns this default tablespace as the undo tablespace of the instance. This undo tablespace allocates disk space from the default files used by the `CREATE DATABASE` statement, and it has an initial extent of 10M. Oracle Database handles the system-generated data file as described in "["DATAFILE Clause"](#)". If Oracle Database is unable to create the undo tablespace, then the entire `CREATE DATABASE` operation fails.

 **See Also:**

- *Oracle Database Administrator's Guide* for information on automatic undo management and undo tablespaces
- [CREATE TABLESPACE](#) for information on creating an undo tablespace after database creation

### **`set_time_zone_clause`**

Use the `SET TIME_ZONE` clause to set the time zone of the database. You can specify the time zone in two ways:

- By specifying a displacement from UTC (Coordinated Universal Time—formerly Greenwich Mean Time). The valid range of `hh:mi` is -12:00 to +14:00.
- By specifying a time zone region. To see a listing of valid time zone region names, query the `TZNAME` column of the `V$TIMEZONE_NAMES` dynamic performance view.

 **Note:**

Oracle recommends that you set the database time zone to UTC (0:00). Doing so can improve performance, especially across databases, as no conversion of time zones will be required.

 **See Also:**

*Oracle Database Reference* for information on the dynamic performance views

Oracle Database normalizes all `TIMESTAMP WITH LOCAL TIME ZONE` data to the time zone of the database when the data is stored on disk. If you do not specify the `SET TIME_ZONE` clause, then the database uses the operating system time zone of the server. If the operating system time zone is not a valid Oracle Database time zone, then the database time zone defaults to UTC.

### **`USER_DATA TABLESPACE Clause`**

This clause lets you create a tablespace that is used for storing user data and database options such as Oracle XML DB.

If you specify this clause when creating a multitenant container database (CDB), then the tablespace is created as part of the seed. Pluggable databases (PDBs) subsequently created using the seed will include this tablespace and its data file. The tablespace and data file specified in this clause are not used by the root.

Specify `BIGFILE` or `SMALLFILE` to determine whether the tablespace is a bigfile or smallfile tablespace. If you omit these clauses, then Oracle Database creates a tablespace of the type that you specify with the `SET DEFAULT TABLESPACE` clause. If you do not specify the `SET DEFAULT TABLESPACE` clause, then Oracle Database creates a smallfile tablespace. These clauses have the same semantics as in the "["SET DEFAULT TABLESPACE Clause "](#)".

Use the `datafile_tempfile_spec` clause to specify one or more data files for the tablespace. Refer to [datafile\\_tempfile\\_spec](#) for the full semantics of this clause.

### **`enable_pluggable_database`**

Starting with Oracle Database 21c, the `ENABLE_PLUGGABLE_DATABASE` initialization parameter is set to `TRUE` by default. If you set the `ENABLE_PLUGGABLE_DATABASE` initialization parameter to `FALSE`, the command will fail.

The `CREATE DATABASE enable_pluggable_database` statement creates a CDB that contains a root and a seed container. You then create PDBs in the CDB by using the `CREATE PLUGGABLE DATABASE` statement.

#### See Also:

- Creating and configuring a cdb.
- [CREATE PLUGGABLE DATABASE](#)
- ["Creating a CDB: Example"](#)

### **`file_name_convert`**

Use the `file_name_convert` clause to determine how the database generates the names of files (such as data files and wallet files) associated with the seed by using the names of files associated with the root.

- For `filename_pattern`, specify a string found in file names associated with the root.
- For `replacement_filename_pattern`, specify a replacement string.

Oracle Database will replace `filename_pattern` with `replacement_filename_pattern` when generating the names of files associated with the seed.

File name patterns cannot match files or directories managed by Oracle Managed Files.

You can specify `FILE_NAME_CONVERT = NONE`, which is the same as omitting this clause. If you omit this clause, then the database first attempts to use Oracle Managed Files to generate seed file names. If you are not using Oracle Managed Files, then the database uses the `PDB_FILE_NAME_CONVERT` initialization parameter to generate file names. If this parameter is not set, then an error occurs.

### **`tablespace_datafile_clauses`**

Use these clauses to specify attributes for all data files comprising the `SYSTEM` and `SYSAUX` tablespaces in the seed PDB. If you do not specify `SIZE size_clause`, then the data file size for a given tablespace will be set to a predetermined fraction of the size of the corresponding root data file. If you do not specify the `autoextend_clause`, then those values are inherited from the root.

Refer to `size_clause` and `autoextend_clause` for the full semantics of these clauses.

### **`undo_mode_clause`**

This clause lets you specify local undo mode or shared undo mode for the CDB.

- Use `LOCAL UNDO ON` to specify local undo mode for the CDB. In this mode, every container in the CDB uses local undo.

- Use LOCAL UNDO OFF to specify shared undo mode for the CDB. In this mode, there is one active undo tablespace for a single-instance CDB, or for an Oracle RAC CDB, there is one active undo tablespace for each instance.

If you omit this clause, then the default is LOCAL UNDO OFF.

## USING MIRROR COPY

Use this clause to create a database with *new\_database\_name* using the prepared files of the mirror copy, identified by *mirror\_name*.

### Examples

#### Creating a Database: Example

The following statement creates a database and fully specifies each argument:

```
CREATE DATABASE sample
  CONTROLFILE REUSE
  LOGFILE
    GROUP 1 ('diskx:log1.log', 'disky:log1.log') SIZE 50K,
    GROUP 2 ('diskx:log2.log', 'disky:log2.log') SIZE 50K
  MAXLOGFILES 5
  MAXLOGHISTORY 100
  MAXDATAFILES 10
  MAXINSTANCES 2
  ARCHIVELOG
  CHARACTER SET AL32UTF8
  NATIONAL CHARACTER SET AL16UTF16
  DATAFILE
    'disk1:df1.dbf' AUTOEXTEND ON,
    'disk2:df2.dbf' AUTOEXTEND ON NEXT 10M MAXSIZE UNLIMITED
  DEFAULT TEMPORARY TABLESPACE temp_ts
  UNDO TABLESPACE undo_ts
  SET TIME_ZONE = '+02:00';
```

This example assumes that you have enabled Oracle Managed Files by specifying a value for the DB\_CREATE\_FILE\_DEST parameter in your initialization parameter file. Therefore no file specification is needed for the DEFAULT TEMPORARY TABLESPACE and UNDO TABLESPACE clauses.

#### Creating a CDB: Example

The following statement creates a CDB newcdb. The ENABLE PLUGGABLE DATABASE clause indicates that a CDB is being created. The CDB will contain a root (CDB\$ROOT) and a seed (PDB\$SEED). The FILE\_NAME\_CONVERT clause specifies that names of files for the seed will be generated by replacing /u01/app/oracle/oradata/newcdb in the names of files associated with the root with /u01/app/oracle/oradata/pdbseed.

```
CREATE DATABASE newcdb
  USER SYS IDENTIFIED BY sys_password
  USER SYSTEM IDENTIFIED BY system_password
  LOGFILE GROUP 1 ('/u01/logs/my/redo01a.log','/u02/logs/my/redo01b.log')
    SIZE 100M BLOCKSIZE 512,
  GROUP 2 ('/u01/logs/my/redo02a.log','/u02/logs/my/redo02b.log')
    SIZE 100M BLOCKSIZE 512,
  GROUP 3 ('/u01/logs/my/redo03a.log','/u02/logs/my/redo03b.log')
    SIZE 100M BLOCKSIZE 512
  MAXLOGHISTORY 1
  MAXLOGFILES 16
```

```
MAXLOGMEMBERS 3
MAXDATAFILES 1024
CHARACTER SET AL32UTF8
NATIONAL CHARACTER SET AL16UTF16
EXTENT MANAGEMENT LOCAL
DATAFILE '/u01/app/oracle/oradata/newcdb/system01.dbf'
  SIZE 700M REUSE AUTOEXTEND ON NEXT 10240K MAXSIZE UNLIMITED
SYSAUX DATAFILE '/u01/app/oracle/oradata/newcdb/sysaux01.dbf'
  SIZE 550M REUSE AUTOEXTEND ON NEXT 10240K MAXSIZE UNLIMITED
DEFAULT TABLESPACE deftbs
  DATAFILE '/u01/app/oracle/oradata/newcdb/deftbs01.dbf'
    SIZE 500M REUSE AUTOEXTEND ON MAXSIZE UNLIMITED
DEFAULT TEMPORARY TABLESPACE tempts1
  TEMPFILE '/u01/app/oracle/oradata/newcdb/temp01.dbf'
    SIZE 20M REUSE AUTOEXTEND ON NEXT 640K MAXSIZE UNLIMITED
UNDO TABLESPACE undotbs1
  DATAFILE '/u01/app/oracle/oradata/newcdb/undotbs01.dbf'
    SIZE 200M REUSE AUTOEXTEND ON NEXT 5120K MAXSIZE UNLIMITED
ENABLE PLUGGABLE DATABASE
  SEED
  FILE_NAME_CONVERT = ('/u01/app/oracle/oradata/newcdb/',
    '/u01/app/oracle/oradata/pdbseed/')
  SYSTEM DATAFILES SIZE 125M AUTOEXTEND ON NEXT 10M MAXSIZE UNLIMITED
  SYSAUX DATAFILES SIZE 100M
USER_DATA TABLESPACE usertbs
  DATAFILE '/u01/app/oracle/oradata/pdbseed/usertbs01.dbf'
    SIZE 200M REUSE AUTOEXTEND ON MAXSIZE UNLIMITED;
```

## CREATE DATABASE LINK

### Purpose

Use the `CREATE DATABASE LINK` statement to create a database link. A **database link** is a schema object in one database that enables you to access objects on another database. The other database need not be an Oracle Database system. However, to access non-Oracle systems you must use Oracle Heterogeneous Services.

After you have created a database link, you can use it in SQL statements to refer to tables, views, and PL/SQL objects in the other database by appending `@dblink` to the table, view, or PL/SQL object name. You can query a table or view in the other database with the `SELECT` statement. You can also access remote tables and views using any `INSERT`, `UPDATE`, `DELETE`, or `LOCK TABLE` statement.

### See Also:

- *Oracle Database Development Guide* for information about accessing remote tables or views with PL/SQL functions, procedures, packages, and data types
- *Oracle Database Administrator's Guide* for information on distributed database systems
- *Oracle Database Reference* for descriptions of existing database links in the `ALL_DB_LINKS`, `DBA_DB_LINKS`, and `USER_DB_LINKS` data dictionary views and for information on monitoring the performance of existing links through the `V$DBLINK` dynamic performance view
- [ALTER DATABASE LINK](#) for information on altering a database link when the password of a connection or authentication user changes.
- [DROP DATABASE LINK](#) for information on dropping existing database links
- [INSERT](#) , [UPDATE](#) , [DELETE](#) , and [LOCK TABLE](#) for using links in DML operations

### Prerequisites

To create a private database link, you must have the `CREATE DATABASE LINK` system privilege. To create a public database link, you must have the `CREATE PUBLIC DATABASE LINK` system privilege. Also, you must have the `CREATE SESSION` system privilege on the remote Oracle Database.

Oracle Net must be installed on both the local and remote Oracle Databases.

### Syntax

***create\_database\_link ::=***

(*dblink::=*)

***dblink\_authentication::=*****Semantics****SHARED**

Specify `SHARED` to create a database link that can be shared by multiple sessions using a single network connection from the source database to the target database. In a shared server configuration, shared database links can keep the number of connections into the remote database from becoming too large. Shared links are typically also public database links. However, a shared private database link can be useful when many clients access the same local schema, and therefore use the same private database link.

In a shared database link, multiple sessions in the source database share the same connection to the target database. Once a session is established on the target database, that session is disassociated from the connection, to make the connection available to another session on the source database. To prevent an unauthorized session from attempting to connect through the database link, when you specify `SHARED` you must also specify the `dblink_authentication` clause for the users authorized to use the database link.

**See Also:**

[Oracle Database Administrator's Guide](#) for more information about shared database links

**PUBLIC**

Specify `PUBLIC` to create a public database link visible to all users. If you omit this clause, then the database link is private and is available only to you.

The data accessible on the remote database depends on the identity the database link uses when connecting to the remote database:

- If you specify `CONNECT TO user IDENTIFIED BY password`, then the database link connects with the specified user and password.
- If you specify `CONNECT TO CURRENT_USER`, then the database link connects with the user in effect based on the scope in which the link is used.
- If you omit both of those clauses, then the database link connects to the remote database as the locally connected user.

**See Also:**

["Defining a Public Database Link: Example"](#)

### ***dblink***

Specify the complete or partial name of the database link. If you specify only the database name, then Oracle Database implicitly appends the database domain of the local database.

Use only ASCII characters for *dblink*. Multibyte characters are not supported. The database link name is case insensitive and is stored in uppercase ASCII characters. If you specify the database name as a quoted identifier, then the quotation marks are silently ignored.

If the value of the `GLOBAL_NAMES` initialization parameter is `TRUE`, then the database link must have the same name as the database to which it connects. If the value of `GLOBAL_NAMES` is `FALSE`, and if you have changed the global name of the database, then you can specify the global name.

The maximum number of database links that can be open in one session or one instance of an Oracle RAC configuration depends on the value of the `OPEN_LINKS` and `OPEN_LINKS_PER_INSTANCE` initialization parameters.

### **Restriction on Creating Database Links**

You cannot create a database link in another user's schema, and you cannot qualify *dblink* with the name of a schema. Periods are permitted in names of database links, so Oracle Database interprets the entire name, such as `ralph.linktosales`, as the name of a database link in your schema rather than as a database link named `linktosales` in the schema `ralph`.

#### **See Also:**

- ["References to Objects in Remote Databases"](#) for guidelines for naming database links
- *Oracle Database Reference* for information on the `GLOBAL_NAMES`, `OPEN_LINKS`, and `OPEN_LINKS_PER_INSTANCE` initialization parameters
- ["RENAME GLOBAL\\_NAME Clause"](#) (an `ALTER DATABASE` clause) for information on changing the database global name

### **IF NOT EXISTS**

Specifying `IF NOT EXISTS` has the following effects:

- If the database link does not exist, a new database link is created at the end of the statement.
- If the database link exists, this is the database link you have at the end of the statement. A new one is not created because the older database link is detected.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

## CONNECT TO Clause

The CONNECT TO clause lets you specify the user and credentials, if any, to be used to connect to the remote database.

## CURRENT\_USER Clause

Specify CURRENT\_USER to create a **current user database link**. The current user must be a global user with a valid account on the remote database.

If the database link is used directly rather than from within a stored object, then the current user is the same as the connected user.

When executing a stored object (such as a procedure, view, or trigger) that initiates a database link, CURRENT\_USER is the name of the user that owns the stored object, and not the name of the user that called the object. For example, if the database link appears inside procedure scott.p (created by scott), and user jane calls procedure scott.p, then the current user is scott.

However, if the stored object is an invoker-rights function, procedure, or package, then the invoker's authorization ID is used to connect as a remote user. For example, if the privileged database link appears inside procedure scott.p (an invoker-rights procedure created by scott), and user Jane calls procedure scott.p, then CURRENT\_USER is jane and the procedure executes with Jane's privileges.

### See Also:

- [CREATE FUNCTION](#) for more information on invoker-rights functions
- ["Defining a CURRENT\\_USER Database Link: Example"](#)

## *user IDENTIFIED BY password*

Specify the user name and password used to connect to the remote database using a **fixed user database link**. If you omit this clause, then the database link uses the user name and password of each user who is connected to the database. This is called a **connected user database link**.

You can set the password to a maximum length of 1024 bytes.

### See Also:

- ["Defining a Fixed-User Database Link: Example"](#)

## *dblink\_authentication*

You can specify this clause only if you are creating a shared database link—that is, you have specified the SHARED clause. Specify the username and password on the target instance. This clause authenticates the user to the remote server and is required for security. The specified username and password must be a valid username and password on the remote instance.

The username and password are used only for authentication. No other operations are performed on behalf of this user.

### CONNECT WITH Clause

Use `CONNECT WITH` to specify the credential object that stores the username and password to connect to the remote database.

You can create, update, or drop the credential using the `DBMS_CREDENTIAL` package.

You can use a credential object belonging to another user, if that user has granted you execute privileges on the credential object.

### USING 'connect string'

Specify the service name of a remote database. If you specify only the database name, then Oracle Database implicitly appends the database domain to the connect string to create a complete service name. Therefore, if the database domain of the remote database is different from that of the current database, then you must specify the complete service name.

#### See Also:

*Oracle Database Administrator's Guide* for information on specifying remote databases

## Examples

The examples that follow assume two databases, one with the database name `local` and the other with the database name `remote`. The examples use the Oracle Database domain. Your database domain will be different.

### Defining a Public Database Link: Example

The following statement defines a shared public database link named `remote` that refers to the database specified by the service name `remote`:

```
CREATE PUBLIC DATABASE LINK remote
  USING 'remote';
```

This database link allows user `hr` on the `local` database to update a table on the `remote` database (assuming `hr` has appropriate privileges):

```
UPDATE employees@remote
  SET salary=salary*1.1
  WHERE last_name = 'Baer';
```

### Defining a Fixed-User Database Link: Example

In the following statement, user `hr` on the `remote` database defines a fixed-user database link named `local` to the `hr` schema on the `local` database:

```
CREATE DATABASE LINK local
  CONNECT TO hr IDENTIFIED BY password
  USING 'local';
```

After this database link is created, hr can query tables in the schema hr on the local database in this manner:

```
SELECT * FROM employees@local;
```

User hr can also use DML statements to modify data on the local database:

```
INSERT INTO employees@local
  (employee_id, last_name, email, hire_date, job_id)
VALUES (999, 'Claus', 'sclaus@example.com', SYSDATE, 'SH_CLERK');

UPDATE jobs@local SET min_salary = 3000
  WHERE job_id = 'SH_CLERK';

DELETE FROM employees@local
  WHERE employee_id = 999;
```

Using this fixed database link, user hr on the remote database can also access tables owned by other users on the same database. This statement assumes that user hr has the READ or SELECT privilege on the oe.customers table. The statement connects to the user hr on the local database and then queries the oe.customers table:

```
SELECT * FROM oe.customers@local;
```

### Defining a CURRENT\_USER Database Link: Example

The following statement defines a current-user database link to the remote database, using the entire service name as the link name:

```
CREATE DATABASE LINK remote.us.example.com
  CONNECT TO CURRENT_USER
  USING 'remote';
```

The user who issues this statement must be a global user registered with the LDAP directory service.

You can create a synonym to hide the fact that a particular table is on the remote database. The following statement causes all future references to emp\_table to access the employees table owned by hr on the remote database:

```
CREATE SYNONYM emp_table
  FOR oe.employees@remote.us.example.com;
```

## CREATE DIMENSION

### Purpose

Use the CREATE DIMENSION statement to create a **dimension**. A dimension defines a parent-child relationship between pairs of column sets, where all the columns of a column set must come from the same table. However, columns in one column set (called a **level**) can come from a different table than columns in another set. The optimizer uses these relationships with materialized views to perform **query rewrite**. The SQL Access Advisor uses these relationships to recommend creation of specific materialized views.

 **Note:**

Oracle Database does not automatically validate the relationships you declare when creating a dimension. To validate the relationships specified in the `hierarchy_clause` and the `dimension_join_clause` of CREATE DIMENSION, you must run the DBMS OLAP.VALIDATE\_DIMENSION procedure.

 **See Also:**

- [CREATE MATERIALIZED VIEW](#) for more information on materialized views
- *Oracle Database SQL Tuning Guide* for more information on query rewrite, the optimizer and the SQL Access Advisor

### Prerequisites

To create a dimension in your own schema, you must have the CREATE DIMENSION system privilege. To create a dimension in another user's schema, you must have the CREATE ANY DIMENSION system privilege. In either case, you must have the READ or SELECT object privilege on any objects referenced in the dimension.

### Syntax

***create\_dimension ::=***

***level\_clause ::=***

***hierarchy\_clause ::=***

***dimension\_join\_clause ::=***

***attribute\_clause ::=***

***extended\_attribute\_clause ::=***

## Semantics

### ***schema***

Specify the schema in which the dimension will be created. If you do not specify `schema`, then Oracle Database creates the dimension in your own schema.

### ***dimension***

Specify the name of the dimension. The name must satisfy the requirements listed in "Database Object Naming Rules".

### ***level\_clause***

The `level_clause` defines a level in the dimension. A level defines dimension hierarchies and attributes.

### ***level***

Specify the name of the level.

### ***level\_table . level\_column***

Specify the columns in the level. You can specify up to 32 columns. The tables you specify in this clause must already exist.

#### **SKIP WHEN NULL**

Specify this clause to indicate that if the specified level is `NULL`, then the level is to be skipped. This clause lets you preserve the hierarchical chain of parent-child relationship by an alternative path that skips over the specified level. See [\*hierarchy\\_clause\*](#).

#### **Restrictions on Dimension Level Columns**

Dimension level columns are subject to the following restrictions:

- All of the columns in a level must come from the same table.
- If columns in different levels come from different tables, then you must specify the `dimension_join_clause`.
- The set of columns you specify must be unique to this level.
- The columns you specify cannot be specified in any other dimension.
- Each `level_column` must be non-null unless the level is specified with `SKIP WHEN NULL`. The non-null columns need not have `NOT NULL` constraints. The column for which you specify `SKIP WHEN NULL` cannot have a `NOT NULL` constraint).

#### ***hierarchy\_clause***

The `hierarchy_clause` defines a linear hierarchy of levels in the dimension. Each hierarchy forms a chain of parent-child relationships among the levels in the dimension. Hierarchies in a dimension are independent of each other. They may, but need not, have columns in common.

Each level in the dimension should be specified at most once in this clause, and each level must already have been named in the `level_clause`.

#### ***hierarchy***

Specify the name of the hierarchy. This name must be unique in the dimension.

#### ***child\_level***

Specify the name of a level that has an n:1 relationship with a parent level. The `level_columns` of `child_level` cannot be null, and each `child_level` value uniquely determines the value of the next named `parent_level`.

If the child `level_table` is different from the parent `level_table`, then you must specify a join relationship between them in the `dimension_join_clause`.

#### ***parent\_level***

Specify the name of a level.

#### ***dimension\_join\_clause***

The `dimension_join_clause` lets you specify an inner equijoin relationship for a dimension whose columns are contained in multiple tables. This clause is required and permitted only when the columns specified in the hierarchy are not all in the same table.

***child\_key\_column***

Specify one or more columns that are join-compatible with columns in the parent level.

If you do not specify the schema and table of each *child\_column*, then the schema and table are inferred from the CHILD OF relationship in the *hierarchy\_clause*. If you do specify the schema and column of a *child\_key\_column*, then the schema and table must match the schema and table of columns in the child of *parent\_level* in the *hierarchy\_clause*.

***parent\_level***

Specify the name of a level.

**Restrictions on Join Dimensions**

Join dimensions are subject to the following restrictions:

- You can specify only one *dimension\_join\_clause* for a given pair of levels in the same hierarchy.
- The *child\_key\_columns* must be non-null, and the parent key must be unique and non-null. You need not define constraints to enforce these conditions, but queries may return incorrect results if these conditions are not true.
- Each child key must join with a key in the *parent\_level* table.
- Self-joins are not permitted. The *child\_key\_columns* cannot be in the same table as *parent\_level*.
- All of the child key columns must come from the same table.
- The number of child key columns must match the number of columns in *parent\_level*, and the columns must be joinable.
- You cannot specify multiple child key columns unless the parent level consists of multiple columns.

***attribute\_clause***

The *attribute\_clause* lets you specify the columns that are uniquely determined by a hierarchy level. The columns in *level* must all come from the same table as the *dependent\_columns*. The *dependent\_columns* need not have been specified in the *level\_clause*.

For example, if the hierarchy levels are city, state, and country, then city might determine mayor, state might determine governor, and country might determine president.

***extended\_attribute\_clause***

This clause lets you specify an attribute name for one or more level-to-column relations. The type of attribute you create with this clause is not different from the type of attribute created using the *attribute\_clause*. The only difference is that this clause lets you assign a name to the attribute that is different from the level name.

**Examples****Creating a Dimension: Examples**

This statement was used to create the `customers_dim` dimension in the sample schema sh:

```

CREATE DIMENSION customers_dim
  LEVEL customer IS (customers.cust_id)
  LEVEL city IS (customers.cust_city)
  LEVEL state IS (customers.cust_state_province)
  LEVEL country IS (countries.country_id)
  LEVEL subregion IS (countries.country_subregion)
  LEVEL region IS (countries.country_region)
  HIERARCHY geog_rollup (
    customer CHILD OF
    city CHILD OF
    state CHILD OF
    country CHILD OF
    subregion CHILD OF
    region
    JOIN KEY (customers.country_id) REFERENCES country
  )
  ATTRIBUTE customer DETERMINES
  (cust_first_name, cust_last_name, cust_gender,
  cust_marital_status, cust_year_of_birth,
  cust_income_level, cust_credit_limit)
  ATTRIBUTE country DETERMINES (countries.country_name)
;

```

### **Creating a Dimension with Extended Attributes: Example**

Alternatively, the `extended_attribute_clause` could have been used instead of the `attribute_clause`, as shown in the following example:

```

CREATE DIMENSION customers_dim
  LEVEL customer IS (customers.cust_id)
  LEVEL city IS (customers.cust_city)
  LEVEL state IS (customers.cust_state_province)
  LEVEL country IS (countries.country_id)
  LEVEL subregion IS (countries.country_subregion)
  LEVEL region IS (countries.country_region)
  HIERARCHY geog_rollup (
    customer CHILD OF
    city CHILD OF
    state CHILD OF
    country CHILD OF
    subregion CHILD OF
    region
    JOIN KEY (customers.country_id) REFERENCES country
  )
  ATTRIBUTE customer_info LEVEL customer DETERMINES
  (cust_first_name, cust_last_name, cust_gender,
  cust_marital_status, cust_year_of_birth,
  cust_income_level, cust_credit_limit)
  ATTRIBUTE country DETERMINES (countries.country_name);

```

### **Creating a Dimension with NULL Column Values: Example**

The following example shows how to create the dimension if one of the level columns is null and you want to preserve the hierarchical chain. The example uses the `cust_marital_status` column for simplicity because it is not a `NOT NULL` column. If it had such a constraint, then you would have to disable the constraint before using the `SKIP WHEN NULL` clause.

```

CREATE DIMENSION customers_dim
  LEVEL customer IS (customers.cust_id)
  LEVEL status IS (customers.cust_marital_status) SKIP WHEN NULL

```

---

```
LEVEL city IS (customers.cust_city)
LEVEL state IS (customers.cust_state_province)
LEVEL country IS (countries.country_id)
LEVEL subregion IS (countries.country_subregion) SKIP WHEN NULL
LEVEL region IS (countries.country_region)
HIERARCHY geog_rollup (
    customer CHILD OF
    city CHILD OF
    state CHILD OF
    country CHILD OF
    subregion CHILD OF
    region
    JOIN KEY (customers.country_id) REFERENCES country
)
ATTRIBUTE customer DETERMINES
(cust_first_name, cust_last_name, cust_gender,
cust_marital_status, cust_year_of_birth,
cust_income_level, cust_credit_limit)
ATTRIBUTE country DETERMINES (countries.country_name)
;
```

## CREATE DIRECTORY

### Purpose

Use the CREATE DIRECTORY statement to create a directory object. A directory object specifies an alias for a directory on the server file system where external binary file LOBs (BFILEs) and external table data are located. You can use directory names when referring to BFILEs in your PL/SQL code and OCI calls, rather than hard coding the operating system path name, for management flexibility.

All directories are created in a single namespace and are not owned by an individual schema. You can secure access to the BFILEs stored within the directory structure by granting object privileges on the directories to specific users.

#### See Also:

- ["Large Object \(LOB\) Data Types"](#) for more information on BFILE objects
- [GRANT](#) for more information on granting object privileges
- [external\\_table\\_clause ::= of CREATE TABLE](#)

### Prerequisites

You must have the CREATE ANY DIRECTORY system privilege to create directories.

When you create a directory, you are automatically granted the READ, WRITE, and EXECUTE object privileges on the directory, and you can grant these privileges to other users and roles. The DBA can also grant these privileges to other users and roles.

WRITE privileges on a directory are useful in connection with external tables. They let the grantee determine whether the external table agent can write a log file or a bad file to the directory.

For file storage, you must also create a corresponding operating system directory, an Oracle Automatic Storage Management (Oracle ASM) disk group, or a directory within an Oracle ASM disk group. Your system or database administrator must ensure that the operating system directory has the correct read and write permissions for Oracle Database processes.

Privileges granted for the directory are created independently of the permissions defined for the operating system directory, and the two may or may not correspond exactly. For example, an error occurs if sample user `hr` is granted `READ` privilege on the directory object but the corresponding operating system directory does not have `READ` permission defined for Oracle Database processes.

### Restrictions

Symbolic links are not allowed in the directory object paths or filenames when opening `BFILE` objects. The entire directory path and filename is checked and the following error is returned if any symbolic link is found:

```
ORA-22288: file or LOB operation FILEOPEN failed soft link in path
```

### Workaround

If the database directory object or filename you are trying to open contains symbolic links, change it to provide the real path and filename.

### Syntax

`create_directory ::=`

### Semantics

#### OR REPLACE

Specify `OR REPLACE` to re-create the directory database object if it already exists. You can use this clause to change the definition of an existing directory without dropping, re-creating, and regranting database object privileges previously granted on the directory.

Users who had previously been granted privileges on a redefined directory can still access the directory without being regranted the privileges.

 See Also:

[DROP DIRECTORY](#) for information on removing a directory from the database

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the directory does not exist, a new directory is created at the end of the statement.
- If the directory exists, this is the directory you have at the end of the statement. A new one is not created because the older one is detected.

You can have `one of OR REPLACE or IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error:  
`ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

### SHARING

This clause applies only when creating a directory in an application root. This type of directory is called an application common object and it can be shared with the application PDBs that belong to the application root. To determine how the directory is shared, specify one of the following sharing attributes:

- `METADATA` - A metadata link shares the directory's metadata, but its data is unique to each container. This type of directory is referred to as a **metadata-linked application common object**.
- `NONE` - The directory is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the directory. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is `METADATA`.

You cannot change the sharing attribute of a directory after it is created.

 See Also:

- *Oracle Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
- *Oracle Database Administrator's Guide* for complete information on creating application common objects

### *directory*

Specify the name of the directory object to be created. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)".

Oracle Database does not verify that the directory you specify actually exists. Therefore, take care that you specify a valid directory in your operating system. In addition, if your operating

system uses case-sensitive path names, then be sure you specify the directory in the correct format. You need not include a trailing slash at the end of the path name.

Do not refer to a parent directory in the directory name. For example, the following syntax is valid:

```
CREATE DIRECTORY mydir AS '/scratch/data/file_data';
```

However, the following syntax is not valid:

```
CREATE DIRECTORY mydir AS '/scratch/../file_data';
```

#### ***path\_name***

Specify the full path name of the operating system directory of the server where the files are located. The single quotation marks are required, with the result that the path name is case sensitive.

#### **Examples**

##### **Creating a Directory: Examples**

The following statement creates a directory database object that points to a directory on the server:

```
CREATE DIRECTORY admin AS '/disk1/oracle/admin';
```

The following statement redefines directory database object `bfile_dir` to enable access to BFILEs stored in the operating system directory `/usr/bin/bfile_dir`:

```
CREATE OR REPLACE DIRECTORY bfile_dir AS '/usr/bin/bfile_dir';
```

## CREATE DISKGROUP

### **Note:**

This SQL statement is valid only if you are using Oracle ASM and you have started an Oracle ASM instance. You must issue this statement from within the Oracle ASM instance, not from a normal database instance. For information on starting an Oracle ASM instance, refer to *Oracle Automatic Storage Management Administrator's Guide*.

#### **Purpose**

Use the `CREATE DISKGROUP` clause to name a group of disks and specify that Oracle Database should manage the group for you. Oracle Database manages a disk group as a logical unit and evenly spreads each file across the disks to balance I/O. Oracle Database also automatically distributes database files across all available disks in disk groups and rebalances storage automatically whenever the storage configuration changes.

This statement creates a disk group, assigns one or more disks to the disk group, and mounts the disk group for the first time. Note that `CREATE DISKGROUP` only mounts a disk group on the local node. If you want Oracle ASM to mount the disk group automatically in subsequent instances, then you must add the disk group name to the

value of the `ASM_DISKGROUPS` initialization parameter in the initialization parameter file. If you use an `SPFILE`, then the disk group is added to the initialization parameter automatically.

 **See Also:**

- [ALTER DISKGROUP](#) for information on modifying disk groups
- *Oracle Automatic Storage Management Administrator's Guide* for information on Oracle ASM and using disk groups to simplify database administration
- `ASM_DISKGROUPS` for more information about adding disk group names to the initialization parameter file
- `V$ASM_OPERATION` for information on monitoring Oracle ASM operations
- [DROP DISKGROUP](#) for information on dropping a disk group

### Prerequisites

You must have the `SYSASM` system privilege to issue this statement.

Before issuing this statement, you must format the disks using an operating system format utility. Also ensure that the Oracle Database user has read/write permission and the disks can be discovered using the `ASM_DISKSTRING`.

When you store your database files in Oracle ASM disk groups, rather than in a file system, before the database instance can access your files in the disk groups, you must configure and start up an Oracle ASM instance to manage the disk groups.

Each database instance communicates with a single Oracle ASM instance on the same node as the database. Multiple database instances on the same node can communicate with a single Oracle ASM instance.

## Syntax

*create\_diskgroup ::=*

*qualified\_disk\_clause ::=*

(*size\_clause ::=*)

*diskgroup\_name*

Specify the name of the disk group. The name must satisfy the requirements listed in "Database Object Naming Rules". However, disk groups are not schema objects.

**Note:**

Oracle does not recommend using quoted identifiers for disk group names. These quoted identifiers are accepted when issuing the CREATE DISKGROUP statement in SQL\*Plus, but they may not be valid when using other tools that manage disk groups.

## REDUNDANCY Clause

The `REDUNDANCY` clause lets you specify the redundancy level of the disk group.

- `NORMAL REDUNDANCY` requires the existence of at least two failure groups (see the `FAILGROUP` clause that follows). Oracle ASM provides redundancy for all files in the disk group according to the attributes specified in the disk group templates. `NORMAL REDUNDANCY` disk groups can tolerate the loss of one group. Refer to `ALTER DISKGROUP ... diskgroup_template_clauses` for more information on disk group templates.

`NORMAL REDUNDANCY` is the default if you omit the `REDUNDANCY` clause. Therefore, if you omit this clause, you must create at least two failure groups, or the create operation will fail.

- `HIGH REDUNDANCY` requires the existence of at least three failure groups. Oracle ASM fixes mirroring at 3-way mirroring, with each extent getting two mirrored copies. `HIGH REDUNDANCY` disk groups can tolerate the loss of two failure groups.
- `FLEX REDUNDANCY` is a type of disk group that allows a database to specify its own redundancy after the disk group is created. A file's redundancy can also be changed after its creation. This type of disk group supports Oracle ASM file groups and quota groups. A flex disk group requires the existence of at least three failure groups. If a flex disk group has fewer than five failure groups, then it can tolerate the loss of one; otherwise, it can tolerate the loss of two failure groups. To create a flex disk group, the `COMPATIBLE.ASM` and `COMPATIBLE.RDBMS` disk group attributes must be set to 12.2 or greater.
- `EXTENDED REDUNDANCY` is a disk group that has all the features of a flex disk group in addition to being highly available in an extended cluster environment. The cluster contains nodes that span multiple physically separated sites. For more see [About Oracle ASM Extended Disk Groups](#)

You can use the `SITE` keyword to specify the redundancy of files and file groups in an extended disk group for each site, rather than for each disk group.

- `EXTERNAL REDUNDANCY` indicates that Oracle ASM does not provide any redundancy for the disk group. The disks within the disk group must provide redundancy (for example, using a storage array), or you must be willing to tolerate loss of the disk group if a disk fails (for example, in a test environment). You cannot specify the `FAILGROUP` clause if you specify `EXTERNAL REDUNDANCY`.

You cannot change the redundancy level after the disk group has been created, with the following exception: You can convert a normal or high redundancy disk group to a flex disk group. For more information, see the [convert\\_redundancy\\_clause](#) of `ALTER DISKGROUP`.

## QUORUM | REGULAR

Use these keywords to qualify either failure group or disk specifications.

- `REGULAR` disks, or disks in non-quorum failure groups, can contain any files.
- `QUORUM` disks, or disks in quorum failure groups, cannot contain any database files, the Oracle Cluster Registry (OCR), or dynamic volumes. However, `QUORUM` disks can contain the voting file for Cluster Synchronization Services (CSS). Oracle ASM uses quorum disks or disks in quorum failure groups for voting files whenever possible.

A quorum failure group is not considered when determining redundancy requirements with respect to storing user data.

If you specify neither keyword, then `REGULAR` is the default.

Specify either QUORUM or REGULAR before the keyword FAILGROUP if you are explicitly specifying the failure group. If you are creating a disk group with implicitly created failure groups, then specify these keywords before the keyword DISK.

 **See Also:**

*Oracle Automatic Storage Management Administrator's Guide* for more information about quorum and regular disks and failure groups

### FAILGROUP Clause

Use this clause to specify a name for one or more failure groups. If you omit this clause, and you have specified NORMAL or HIGH REDUNDANCY, then Oracle Database automatically adds each disk in the disk group to its own failure group. The implicit name of the failure group is the same as the operating system independent disk name (see "NAME Clause").

You cannot specify this clause if you are creating an EXTERNAL REDUNDANCY disk group.

#### ***qualified\_disk\_clause***

Specify DISK *qualified\_disk\_clause* to add a disk to a disk group.

#### ***search\_string***

For each disk you are adding to the disk group, specify the operating system dependent search string that Oracle ASM will use to find the disk. The *search\_string* must point to a subset of the disks returned by discovery using the strings in the ASM\_DISKSTRING initialization parameter. If *search\_string* does not point to any disks the Oracle Database user has read/write access to, then Oracle ASM returns an error. If it points to one or more disks that have already been assigned to a different disk group, then Oracle Database returns an error unless you also specify FORCE.

For each valid candidate disk, Oracle ASM formats the disk header to indicate that it is a member of the new disk group.

 **See Also:**

The ASM\_DISKSTRING initialization parameter for more information on specifying the search string

### NAME Clause

The NAME clause is valid only if the *search\_string* points to a single disk. This clause lets you specify an operating system independent name for the disk. The name can be up to 30 characters long and can contain only alphanumeric characters. The first character must be alphabetic. If you omit this clause and you assigned a label to a disk through ASMLIB, then that label is used as the disk name. If you omit this clause and you did not assign a label through ASMLIB, then Oracle ASM creates a default name of the form *diskgroupname\_####*, where #### is the disk number. You use this name to refer to the disk in subsequent Oracle ASM operations.

**SIZE Clause**

Use this clause to specify in bytes the size of the disk. If you specify a size greater than the capacity of the disk, then Oracle ASM returns an error. If you specify a size less than the capacity of the disk, then you limit the disk space Oracle ASM will use. The size value must be identical for all disks in a disk group. If you omit this clause, then Oracle ASM attempts programmatically to determine the size of the disk.

**FORCE**

Specify `FORCE` if you want Oracle ASM to add the disk to the disk group even if the disk is already a member of a different disk group.

 **Note:**

Using `FORCE` in this way may destroy existing disk groups.

For this clause to be valid, the disk must already be a member of a disk group and the disk cannot be part of a mounted disk group.

**NOFORCE**

Specify `NOFORCE` if you want Oracle ASM to return an error if the disk is already a member of a different disk group. `NOFORCE` is the default.

**ATTRIBUTE Clause**

Use this clause to set attribute values for the disk group. You can view the current attribute values by querying the `V$ASM_ATTRIBUTE` view. [Table 13-2](#) lists the attributes you can set with this clause. All attribute values are strings.

**Table 13-2 Disk Group Attributes**

Attribute	Valid Values	Description
<code>ACCESS_CONTROL.ENABLED</code>	true or false	<p>Specifies whether Oracle ASM File Access Control is enabled for a disk group. If set to <code>true</code>, accessing Oracle ASM files is subject to access control. If <code>false</code>, any user can access every file in the disk group. All other operations behave independently of this attribute. The default value is <code>false</code>.</p> <p>If both the <code>compatible.rdbms</code> and <code>compatible.asm</code> attributes are set to at least 11.2, you can set this attribute in an <code>ALTER DISKGROUP ... SET ATTRIBUTE</code> statement. You cannot set this attribute when creating a disk group.</p> <p>When you set up file access control on an existing disk group, the files previously created remain accessible by everyone, unless you run the <code>ALTER DISKGROUP SET PERMISSION</code> statement to restrict the permissions.</p> <p><b>Note:</b> This attribute is used in conjunction with <code>ACCESS_CONTROL.UMASK</code> to manage Oracle ASM File Access Control. After setting the <code>ACCESS_CONTROL.ENABLED</code> disk attribute, you must set permissions with the <code>ACCESS_CONTROL.UMASK</code> attribute.</p>

**Table 13-2 (Cont.) Disk Group Attributes**

Attribute	Valid Values	Description
ACCESS_CONTROL.UMASK	A three-digit number where each digit is 0, 2, or 6.	<p>Determines which permissions are masked out on the creation of an Oracle ASM file for the user that owns the file (first digit), users in the same user group (second digit), and others not in the user group (third digit). This attribute applies to all files on a disk group. Setting to 0 masks out nothing. Setting to 2 masks out write permission. Setting to 6 masks out both read and write permissions. The default value is 066.</p> <p>If both the compatible.rdbms and compatible.asm attributes are set to at least 11.2, you can set this attribute in an ALTER DISKGROUP ... SET ATTRIBUTE statement. You cannot set this attribute when creating a disk group.</p> <p>When you set up file access control on an existing disk group, the files previously created remain accessible by everyone, unless you run the ALTER DISKGROUP SET PERMISSION statement to restrict the permissions.</p> <p><b>Note:</b> This attribute is used in conjunction with ACCESS_CONTROL.ENABLED to manage Oracle ASM File Access Control. Before setting ACCESS_CONTROL.UMASK, you must set ACCESS_CONTROL.ENABLED to true.</p>
AU_SIZE	Size in bytes. Valid values are powers of 2 from 1M to 64M. Examples '4M', '4194304'.	Specifies the allocation unit size. This attribute can be set only during disk group creation; it cannot be modified with an ALTER DISKGROUP statement.
COMPATIBLE.ADVM	Valid Oracle Database version number <sup>1</sup>	<p>Determines whether the disk group can contain Oracle ADVM volumes. The value must be set to 11.2 or higher. Before setting this attribute, the COMPATIBLE.ASM value must be 11.2 or higher. Also, the Oracle ADVM volume drivers must be loaded.</p> <p>By default, the value of the COMPATIBLE.ADVM attribute is empty until set.</p>
COMPATIBLE.ASM	Valid Oracle Database version number <sup>1</sup>	<p>Determines the minimum software version for an Oracle ASM instance that can use the disk group. This setting also affects the format of the data structures for the Oracle ASM metadata on the disk.</p> <p>For Oracle ASM in Oracle Database 11g, 10.1 is the default setting for the COMPATIBLE.ASM attribute when using the SQL CREATE DISKGROUP statement, the ASMCMD mkdg command, and Oracle Enterprise Manager <b>Create Disk Group</b> page.</p> <p>When creating a disk group with ASMCA, the default setting is 11.2.</p>

**Table 13-2 (Cont.) Disk Group Attributes**

<b>Attribute</b>	<b>Valid Values</b>	<b>Description</b>
COMPATIBLE.RDBMS	Valid Oracle Database version number <sup>1</sup>	<p>Determines the minimum COMPATIBLE database initialization parameter setting for any database instance that is allowed to use the disk group.</p> <p>Before advancing the COMPATIBLE.RDBMS attribute, ensure that the values for the COMPATIBLE initialization parameter for all of the databases that access the disk group are set to at least the value of the new setting for COMPATIBLE.RDBMS. For example, if the COMPATIBLE initialization parameters of the databases are set to either 11.1 or 11.2, then COMPATIBLE.RDBMS can be set to any value between 10.1 and 11.1 inclusively.</p> <p>For Oracle ASM in Oracle Database 11g, 10.1 is the default setting for the COMPATIBLE.RDBMS attribute when using the SQL CREATE DISKGROUP statement, the ASMCMD mkdg command, ASMCA <b>Create Disk Group</b> page, and Oracle Enterprise Manager <b>Create Disk Group</b> page.</p>
CONTENT.CHECK	true or false	<p>Enables (true) or disables (false) content checking when performing data copy operations for rebalancing a disk group. You cannot set this attribute when creating a disk group.</p> <p>The default value is dependent on the COMPATIBLE.ASM attribute and follows this rule:</p> <ul style="list-style-type: none"> <li>• If COMPATIBLE.ASM &gt; = 19.0.0.0.0, then CONTENT.CHECK defaults to true.</li> <li>• If COMPATIBLE.ASM &lt; 19.0.0.0.0, then CONTENT.CHECK defaults to false.</li> </ul> <p><b>Note:</b> This rule is ONLY true for the creation of new diskgroups. If the COMPATIBLE.ASM attribute of an existing diskgroup is updated to 19.0.0.0.0 or above, the CONTENT.CHECK attribute remains at its current value.</p>
DISK_REPAIR_TIME	0 to 136 years	<p>When disks are taken offline, Oracle ASM drops them after a default period of time. If both the compatible.rdbms and compatible.asm attributes are set to at least 11.1, you can set the disk_repair_time attribute in an ALTER DISKGROUP ... SET ATTRIBUTE statement to change that default period of time so that the disk can be repaired and brought back online. You cannot set this attribute when creating a disk group.</p> <p>The time can be specified in units of minute (M) or hour (H). The specified time elapses only when the disk group is mounted. If you omit the unit, then the default is H. If you omit this attribute, and both compatible.rdbms and compatible.asm are set to at least 11.1, then the default is 12 H. Otherwise the disk is dropped immediately. You can override this attribute with an ALTER DISKGROUP ... OFFLINE DISK statement and the DROP AFTER clause.</p> <p><b>Note:</b> If a disk is taken offline using the current value of disk_repair_time, and the value of this attribute is subsequently changed, then the changed value is used by Oracle ASM in the disk offline logic.</p> <p><b>See Also:</b> The ALTER DISKGROUP ... <i>disk_offline_clause</i> and <i>Oracle Automatic Storage Management Administrator's Guide</i> for more information</p>

**Table 13-2 (Cont.) Disk Group Attributes**

Attribute	Valid Values	Description
FAILGROUP_REPAIR_TIME	<number>m (number of minutes) or <number>h (number of hours)	<p>Specifies a default repair time for the failure groups in the disk group. The failure group repair time is used if Oracle ASM determines that an entire failure group has failed. The default value is 24 hours (24h).</p> <p>If there is a repair time specified for a disk, such as with the DROP AFTER clause of the ALTER DISKGROUP OFFLINE DISK statement, then that disk repair time overrides the failure group repair time.</p> <p>This attribute can only be set when altering a disk group and is only applicable to normal and high redundancy disk groups.</p>
LOGICAL_SECTOR_SIZE	512, 4096, or 4K	<p>Sets the logical sector size of a disk group. This value specifies the smallest possible I/O that the disk group can accept. The default value is estimated from the disks that join the disk group.</p> <p>To set this disk group attribute during the creation of a disk group or to alter it after a disk group has been created, the COMPATIBLE.ASM disk group attribute must be set to 12.2 or higher.</p>
PHYS_META_REPLICATED	true or false	<p>Tracks the replication status of a disk group. When the Oracle ASM compatibility of a disk group is advanced to 12.0 or higher, the physical metadata of each disk, including its disk header, free space table blocks and allocation table blocks, is replicated. The replication is performed online asynchronously.</p> <p>PHYS_META_REPLICATED is set to true by Oracle ASM if the physical metadata of every disk in the disk group has been replicated.</p> <p>This disk group attribute is only defined in a disk group with the Oracle ASM disk group compatibility (COMPATIBLE.ASM) set to 12.0 and higher. This attribute is read-only and is intended for information only. You cannot set or change its value.</p>
PREFERRED_READ_ENABLED	true or false	<p>In an Oracle extended cluster, which contains nodes that span multiple physically separated sites, the PREFERRED_READ_ENABLED disk group attribute controls whether preferred read functionality is enabled for a disk group. If preferred read functionality is enabled, then this functionality enables an instance to determine and read from disks at the same site as itself, which can improve performance. For extended clusters, the default value is true. For clusters that are not extended (only one physical site), preferred read is disabled (false). Preferred read status applies to extended, normal, high, and flex redundancy disk groups.</p> <p>This disk group attribute is only defined in a disk group with the Oracle ASM disk group compatibility (COMPATIBLE.ASM) set to 12.2 and higher.</p>

**Table 13-2 (Cont.) Disk Group Attributes**

<b>Attribute</b>	<b>Valid Values</b>	<b>Description</b>
SECTOR_SIZE	512, 4096, or 4K	Sets the physical sector size of a disk group. All disks in the disk group must have this physical sector size. The default value is obtained from the disks that join the disk group.  To set this disk group attribute during the creation of a disk group, the COMPATIBLE.ASM and COMPATIBLE.RDBMS disk group attributes must be set to 11.2 or higher. To alter this disk group attribute after a disk group has been created, the COMPATIBLE.ASM disk group attribute must be set to 12.2 or higher.
THIN_PROVISIONED	true or false	Enables (true) or disables (false) the functionality to discard unused storage space after a disk group rebalance is completed. The default value is false.
CONTENT_HARDCHECK	true or false	CONTENT_HARDCHECK enables or disables Hardware Assisted Resilient Data (HARD) checking when performing data copy operations for rebalancing a disk group. This attribute can only be set when altering a disk group.

<sup>1</sup> Specify at least the first two digits of a valid Oracle Database release number. Refer to *Oracle Database Administrator's Guide* for information on specifying valid version numbers. For example, you can specify compatibility as '11.2' or '12.1'.

#### See Also:

*Oracle Automatic Storage Management Administrator's Guide* for more information on managing these attribute settings

#### Examples

The following example assumes that the `ASM_DISKSTRING` parameter is a superset of `/devices/disks/c*`, `/devices/disks/c*` points to at least one device to be used as an Oracle ASM disk, and the Oracle Database user has read/write permission to the disks.

#### See Also:

*Oracle Automatic Storage Management Administrator's Guide* for information on Oracle ASM and using disk groups to simplify database administration

#### Creating a Diskgroup: Example

The following statement creates an Oracle ASM disk group `dgroup_01` where no redundancy for the disk group is provided by Oracle ASM and includes all disks that match the `search_string`:

```
CREATE DISKGROUP dgroup_01
  EXTERNAL REDUNDANCY
  DISK '/devices/disks/c*';
```

# CREATE DOMAIN

## Purpose

Use `CREATE DOMAIN` to create a usage domain. A usage domain is high-level dictionary object that belongs to a schema and encapsulates a set of optional properties and constraints.

You can define table columns to be associated with a domain, thereby explicitly applying the domain's optional properties and constraints to the columns.

At minimum, a domain must specify a built-in Oracle datatype. The qualified domain name should not collide with the qualified user-defined datatypes, or with Oracle built-in datatypes.

The domain datatype must be a single Oracle datatype. For Oracle character data type you must specify a maximum length, one of `VARCHAR2(L [CHAR|BYTE])`, `NVARCHAR2(L)`, `CHAR(L [CHAR|BYTE])`, or `NCHAR(L)`.

## Domain-Specific Expressions and Conditions

A domain expression can be one of *simple*, *datetime*, *interval*, *CASE*, *compound*, or *list domain expression*:

- A *simple domain expression* is one of `string`, `number`, `sequence.CURRVAL`, `sequence.NEXTVAL`, `NULL`, or `schema.domain`. It is similar to simple expressions, except that it references domain names instead of column names. It references domain names as qualified names, names of Oracle built-in domains or uses a `PUBLIC` synonym to a domain.
- A *datetime domain expression* is a datetime expression that references domain expressions only.
- An *interval domain expression* is defined just as a regular interval expression, except that it references domain expressions. For example, `(SYSTIMESTAMP - day_of_week) DAY(9) TO SECOND` is an interval domain expression.
- A *compound domain expression* is any of: `(expr)`, `expr op expr` with `op +, -, *, /, ||`, or `expr COLLATE collation_name`, where `expr` is a domain expression.

## Examples of valid compound domain expressions

- ```
'email: ' || EmailAddress  
  
day_of_week + INTERVAL '1' DAY  
  
TO_CHAR>LastFour(SSN))  
  
• A case domain expression is like a regular case expression except that it references domain expressions only.
```

## Examples of valid case domain expressions

```
CASE  
WHEN UPPER(DOMAIN_DISPLAY(day_of_week)) IN ('SAT','SUN')  
THEN 'weekend'
```

```

    ELSE 'week day'
END

```

- Similar to the definition of usage domain expressions, a domain condition is like a regular SQL condition, except that it references only domain expressions. You can use the keyword `VALUE` in domain expressions instead of the domain name. For example:

```

CREATE DOMAIN day_of_week AS CHAR(3 CHAR)
  CONSTRAINT day_of_week_c
    CHECK (UPPER(VALUE) IN ('MON', 'TUE', 'WED', 'THU', 'FRI', 'SAT', 'SUN'))
  DEFERRABLE INITIALLY DEFERRED
  DISPLAY SUBSTR(VALUE, 1, 2);

```

### JSON Schema Using a Usage Domain

You can register a JSON schema as a usage domain.

The following example creates domain `dj5` as a JSON schema object:

```

CREATE DOMAIN dj5 AS JSON CONSTRAINT dj5chk
  CHECK (dj5 IS JSON validate
    '{'
      "type": "object",
      "properties": {
        "a": {
          "type": "number"
        }
      }
    }'
  );

```

You can then create a table `jtab` and associate column `jcol` with the domain `dj5`:

```

CREATE TABLE jtab(
  id NUMBER PRIMARY KEY,
  jcol JSON DOMAIN dj5
);

```

### Prerequisites

To create a domain in your own schema, you must have the `CREATE DOMAIN` system privilege.

To create a domain in another user's schema, you must have the `CREATE ANY DOMAIN` system privilege.

### Syntax

***create\_domain::=***

*create\_single\_column\_domain ::=*

*column\_properties\_clause ::=*

*create\_multi\_column\_domain ::=*

*create\_flexible\_domain ::=*

## CASE Expressions

*result\_expr ::=*

*default\_clause ::=*

*constraint\_clause ::=*

*annotations\_clause ::=*

For the full syntax and semantics of the *annotations\_clause* see [annotations\\_clause](#).

## Semantics

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the domain does not exist, a new domain is created at the end of the statement.
- If the domain exists, a new one is not created because the older one is detected.

Using `IF EXISTS` with `CREATE` results in the following error: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

### domain\_name

`domain_name` follows the same restrictions as any type name and must not collide with the name of any object in the domain schema, any Oracle supplied data type, and any Oracle supplied domain.

These restrictions apply at a PDB-level in a CDB environment.

Note that domains are schema-level catalog objects, and therefore subject to schema-level object restrictions.

**datatype**

*datatype* must be an Oracle built-in data type like:

- CHAR(L [CHAR|BYTE]), NCHAR(L), VARCHAR(L [CHAR|BYTE]), VARCHAR2(L [CHAR|BYTE]), NVARCHAR2(L), LONG
- NUMBER[p, [s]], FLOAT, BINARY\_FLOAT, BINARY\_DOUBLE
- RAW, LONG RAW (extended included)
- DATE, TIMESTAMP (WITH (LOCAL) TIME ZONE), INTERVAL
- BFILE, BLOB, CLOB, NCLOB
- JSON native datatype
- BOOLEAN

**STRICT**

When you specify `STRICT`, table columns linked with the domain must have the same data type limits as the corresponding domain columns. For example, if the data type of a domain column is `NUMBER(10)`, you can only associate it with columns declared as `NUMBER(10)`. Applying the domain to columns of `NUMBER(9)` or `NUMBER(11)` will raise a type error.

If you omit `STRICT`, you can link the domain to columns with type limits greater than or equal to the domain's limit. For example, you can apply a non-strict domain with the data type `NUMBER(10)` to columns with the data type `NUMBER(20)`.

If you associate a column with a domain without specifying the column's data type, then it uses `STRICT` semantics.

**default\_clause**

If you specify the `ON NULL` clause, an implicit `NOT NULL` constraint is added.

**default\_expression**

*default\_expression* must be a domain expression and must conform to all the restrictions on default column expressions of the given datatype, when applied to domain expressions:

- *default\_expression* cannot contain a SQL function that returns a domain reference, or a nested function invocation, and it cannot be a subquery expression.
- The datatype of *default\_expression* must match the domain's specified datatype.
- As a domain expression, *default\_expression* cannot refer to any table or column. It cannot refer to any other domain name.
- *default\_expression* may refer to `NEXTVAL` and `CURRVAL` for a sequence. It cannot reference a PL/SQL function.

***constraint\_clause***

Note that domain constraints can have optional names. They are NOT NULL, NULL or CHECK constraints. Multiple such constraint clauses can be specified both at the column and domain level.

The CHECK conditions as well as expressions in ALTER DOMAIN can only refer to domain columns. If the domain has a single column, the column name is either the domain name or the keyword VALUE, but the same expression cannot contain both domain name and VALUE as column name.

*constraint\_name* is optional. When specified, it must not collide with a name of any other constraint in the domain's schema (in the given PDB if in a CDB environment). When not specified, a system-generated name will be used. Domain constraints follow the same rules as table and column-level constraints: a named table or column-level constraint cannot coincide with the name of any other constraint in the same schema. Domain constraints can share names with tables, even in the same schema. They can share names with columns, and it is possible for a constraint to have the same name as the table or column it is defined on.

The CHECK condition must be a domain logical condition and must conform to all the restrictions on CHECK constraints translated to domain expressions:

- It can only refer to *domain\_name*, like a CHECK constraint on a column can only refer to a column. It cannot refer to any columns in any table or view, even within the domain schema.
- Subquery or scalar query expressions cannot be used.
- Condition cannot refer to non-deterministic functions (like CURRENT\_DATE), or user-defined PL/SQL functions.
- CHECK IS JSON (STRICT) constraints are allowed.

CHECK IS JSON(VALIDATE USING *schema\_constant\_text*) is allowed. You can specify the JSON schema and use it to validate that the JSON column respects the schema definition that is specified. *schema\_constant\_text* can be a constant literal with the JSON schema text, or a bind variable for the JSON schema text. The bind must be a runtime constant. It cannot be a domain.

If you use the IS JSON constraint without specifying VALIDATE USING *schema\_constraint*, any JSON value will be accepted. But when you specify a JSON Schema with VALIDATE USING *schema\_constraint*, and the entered input data into the table column does not follow the schema, a JSON schema validation error is raised.

You can use shorthand syntax to specify the JSON schema with VALIDATE USING *schema\_constant\_text*.

Just as for table and column-level constraints, you can specify only one JSON constraint for a given table column

- The CHECK constraint condition is applied to one value at a time, and it is satisfied if the CHECK condition, with *domain\_name* substituted by the value, evaluates to TRUE or UNKNOWN.

Domain constraints may be enforced in any order.

NULL constraint means that values of the domain are allowed to be NULL, and this is the default.

When `constraint_state` is not specified, the constraint is NOT DEFERABLE INITIALLY IMMEDIATE.

### COLLATE

When collation is specified, it conforms to all the restrictions of column-level or schema-level collation. The datatype must be a character data type if collation is specified.

An error will be raised when creating a table with a column marked of a domain with a collation different than the column's collation.

An error will be raised when altering a column to have a collation different than the collation of the column's domain.

This should ensure the invariant that all columns of a domain with a collation specified have the same collation as that of their domain. If no collation is specified and datatype is collatable, the column's collation will be used if specified, or otherwise the underlying default datatype collation in the domain's schema is used.

If no collation is specified and datatype is collatable, the column's collation will be used if specified.

You can specify the `COLLATE` clause only if the `COMPATIBLE` initialization parameter is set to 12.2 or greater, and the `MAX_STRING_SIZE` initialization parameter is set to EXTENDED.

### *display\_expression*

Use `display_expression` to format the data according to domain specifications. It can be of any data type allowed as a domain data type. `display_expression` must be a domain expression that does not contain table or view columns, subqueries, non-deterministic functions, or PL/SQL functions. It can refer to `domain_name`. If you do not specify collation for the expression, then `display_expression` uses the domain's collation, if it is specified.

### *order\_expression*

Use `order_expression` to order and compare values for domain specifications.

`order_expression` must conform to the same restrictions as `display_expressions`, and additionally must be of a byte or char-comparable data type. It returns `order_expression` with `domain_name` replaced by `expression`, if `order_expression` is specified for the expression's domain, or `expression` otherwise

### *annotations\_clause*

For examples of the `annotations_clause` see the examples at the end.

For the full semantics of the annotations clause see [annotations\\_clause](#).

## FROM Clause of Create Flexible Domain

`expr` and `comparison_expr` reference domain discriminant columns in the list `domain_discriminant_column`.

The `FROM` clause for flexible domain is either a `DECODE` or a `CASE` expression that refers only to discriminant column names (in the list following `CHOOSE DOMAIN USING`) in the

search expressions and has only domain name followed by a list of columns in the result expressions. The columns in the result expression must be only columns in the domain column list (following CREATE FLEXIBLE DOMAIN).

## Examples

### Create Domain year\_of\_birth

The following example creates the single column domain `year_of_birth`. The check constraint ensures that the column's value is an integer with a value greater than or equal to 1900. The display clause formats the output of calls to `domain_display` to either 19-YY or 20-YY, where YY is the last two digits of the value. The order clause sorts calls to `domain_order` in order by the column value minus 1900.

```
CREATE DOMAIN year_of_birth AS NUMBER(4)
    CONSTRAINT CHECK ( (trunc(year_of_birth) = year_of_birth) and (year_of_birth >=
1900) )
    DISPLAY (CASE WHEN year_of_birth < 2000 THEN '19-' ELSE '20-' END) ||
MOD(year_of_birth, 100)
    ORDER year_of_birth-1900 ;
```

### Create Domain day\_of\_week

The following statement creates the single column domain `day_of_week`. The check constraint ensures that its values are one of MON, TUE, WED, THU, FRI, SAT, SUN. The initially deferred clause delays validation of these values until commit time. The order clause ensures the values are sorted by day of week instead of alphabetically when calling `domain_order`.

```
CREATE DOMAIN day_of_week AS CHAR(3 CHAR)
    CONSTRAINT day_of_week_c
        CHECK (day_of_week IN ('MON', 'TUE', 'WED', 'THU', 'FRI', 'SAT', 'SUN'))
    INITIALLY DEFERRED
    ORDER CASE day_of_week
        WHEN 'MON' THEN 0
        WHEN 'TUE' THEN 1
        WHEN 'WED' THEN 2
        WHEN 'THU' THEN 3
        WHEN 'FRI' THEN 4
        WHEN 'SAT' THEN 5
        WHEN 'SUN' THEN 6
        ELSE 7
    END;
```

From 23.3 you can associate columns of data type `CHAR(L CHAR)` with the domain with any value for L.

### Create Domain email

The following example creates the sequence `email_seq`. It then creates the single column domain `email`. This uses the sequence to generate email addresses in the form `nnn@domain.com` when you insert null into columns with this domain, where `nnn` are the numbers generated by the sequence. The constraints ensures that email addresses are of the form `sss@sss.sss`, where `sss` is any nonwhitespace character.

The display clause formats the output of calls to `domain_display` to `---sss.sss`, where `sss` is the nonwhitespace characters after the @ sign.

```
CREATE SEQUENCE IF NOT EXISTS email_seq;
```

```
CREATE DOMAIN email AS VARCHAR2(30)
    DEFAULT ON NULL email_seq.NEXTVAL || '@domain.com'
    CONSTRAINT EMAIL_C CHECK (REGEXP_LIKE (email, '^(\S+)\@(\S+)\.(\S+)$'))
    DISPLAY '---' || SUBSTR(email, INSTR(email, '@') + 1);
```

### Create a Strict Domain dept\_codes

The following statement creates the domain `dept_codes`. The check constraint ensures its values are greater than 99 excluding 200. It adds the annotation `Title` with the value "Domain Annotation". You can only link this domain with columns of type `NUMBER(3)`.

```
CREATE DOMAIN dept_codes AS NUMBER(3) STRICT
    CONSTRAINT dept_chk CHECK (dept_codes > 99 AND dept_codes != 200)
    ANNOTATIONS (Title 'Domain Annotation');
```

### Create Domain hourly\_wages

The following statement creates the single column domain `hourly_wages`. It defaults to 15 when inserting null into columns with this domain. The check constraint ensures the values are between 7 and 1,000.

The display clause returns its value in the format \$999.99 when calling `domain_display`. The order clause multiplies its value by negative one, so sorting by `domain_order` sorts from high to low. It has the annotation `Title` with the value "Domain Annotation".

```
CREATE DOMAIN hourly_wages AS NUMBER(10)
    DEFAULT ON NULL 15
    CONSTRAINT minimal_wage_c
        CHECK (hourly_wages >= 7 AND hourly_wages <= 1000) ENABLE
        DISPLAY TO_CHAR(hourly_wages, '$999.99')
        ORDER ( -1 * hourly_wages )
    ANNOTATIONS (Title 'Domain Annotation');
```

### Add Annotations to a Multi Column Domain US\_City at Column and Domain Levels

The following statement creates the multicolumn domain `US_city`. This has three columns: `name`, `state`, and `zip`. All columns have the `Address` annotation.

The check constraint ensures that the permitted values for state are `CA`, `AZ`, and `TX` and `zip` is less than 100000. The display clause returns calls to `domain_display` in the format `name ||', '|| state ||', '||TO_CHAR(zip)`.

The order clause sorts calls to `domain_order` by the concatenation of `state`, then `zip`, then `name`. The domain has an object level annotation `Title` with the value "Domain Annotation" and three column level annotations `Address` without a value, one for each column.

```
CREATE DOMAIN US_city AS
(
    name AS VARCHAR2(30) ANNOTATIONS (Address),
    state AS VARCHAR2(2) ANNOTATIONS (Address),
    zip AS NUMBER ANNOTATIONS (Address)
)
CONSTRAINT City_CK CHECK(state in ('CA','AZ','TX') and zip < 100000)
DISPLAY name||', '|| state ||', '||TO_CHAR(zip)
```

---

```
ORDER state||', '||TO_CHAR(zip)||', '||name
ANNOTATIONS (Title 'Domain Annotation');
```

### Create a Flexible Domain

The following examples create the flexible domain `expense_details`. To do this, you must first create the domains `flight_details`, `meals_details`, and `lodging_details`. These are multicolumn domains with check constraints to ensure the domain columns store appropriate values for the expense type.

For `flight_details`, this means the `flight_num` are two strings separated by a dash, and the origin and destination are both three character strings.

For `meals_details`, the restaurant is mandatory, the `meal_type` one of Breakfast, Lunch or Dinner, and `diner_count` is non-null.

For `lodging_details`, the hotel must be non-null and the `nights_count` greater than zero.

The flexible domain `expense_details` then chooses between these based on the value in the `typ` column.

In the `FROM DECODE` example:

- if `typ` = Flight, it uses the `flight_details` domain. The flexible domain columns `val1`, `val2`, and `val3` map to `flight_num`, `origin`, and `destination` in the `flight_details` domain.
- if `typ` = Meals, it uses the `meals_details` domain. The flexible domain columns `val1`, `val2`, and `val4` map to `restaurant`, `meal_type`, and `diner_count` respectively in the `meals_details` domain.
- if `typ` = Lodging, it uses the `lodging_details` domain. The flexible domain columns `val1` and `val4` map to `hotel` and `nights_count` respectively in the `lodging_details` domain.

In the `FROM CASE` flexible domain:

- If `typ` starts with letters A-G, it uses the `flight_details` domain.
- If `typ` = Meals, it uses the `meals_details` domain.
- If `typ` starts with Ldg, it uses the `lodging_details` domain.

The column mappings are the same as in the `FROM DECODE` example.

### Create Domain `flight_details`

```
CREATE DOMAIN flight_details AS
(
    flight_num AS VARCHAR2(100) NOT NULL,
    origin AS VARCHAR2(200)
        CONSTRAINT origin_3_char_c CHECK (LENGTH(origin) = 3),
    destination AS VARCHAR2(200)
        CONSTRAINT dest_3_char_c CHECK (LENGTH(destination) = 3)
)
CONSTRAINT flight_c
CHECK
(
    flight_num LIKE '%-%' AND
    origin IS NOT NULL AND
    destination IS NOT NULL
)
CONSTRAINT origin_dest_different_c
```

```

    CHECK (origin <> destination)
DISPLAY flight_num||', '||origin||', '||destination
ORDER flight_num||destination;

```

### Create Domain meals\_details

```

CREATE DOMAIN meals_details AS
(
    restaurant AS VARCHAR2(100) NOT NULL,
    meal_type AS VARCHAR2(200),
    diner_count AS NUMBER
)
CONSTRAINT meals_c
CHECK
(
    restaurant IS NOT NULL AND
    meal_type IN ('Breakfast', 'Lunch', 'Dinner') AND
    diner_count IS NOT NULL
)
DISPLAY meal_type||', '||restaurant||', '||diner_count;

```

### Create Domain lodging\_details

```

CREATE DOMAIN lodging_details AS
(
    hotel AS VARCHAR2(100) NOT NULL,
    nights_count AS NUMBER
)
CONSTRAINT lodging_c
CHECK (hotel IS NOT NULL AND nights_count > 0)
DISPLAY hotel||', '|nights_count;

```

### Create a Flexible Domain expense\_details Using FROM DECODE

```

CREATE FLEXIBLE DOMAIN expense_details (val1, val2, val3, val4)
CHOOSE DOMAIN USING (typ VARCHAR2(10))
FROM DECODE(typ,
    'Flight', flight_details(val1, val2, val3),
    'Meals', meals_details(val1, val2, val4),
    'Lodging', lodging_details(val1, val4));

```

### Create a Flexible Domain expense\_details Using FROM CASE

```

CREATE FLEXIBLE DOMAIN expense_details (val1, val2, val3, val4)
CHOOSE DOMAIN USING(typ VARCHAR2(10))
FROM CASE
    WHEN typ BETWEEN 'A' AND 'G' THEN flight_details(val1, val2, val3)
    WHEN typ = 'Meals' THEN meals_details(val1, val2, val4)
    WHEN typ LIKE 'Lodg%' THEN lodging_details(val1, val4)
END;

```

### Create Domain Specifying a JSON Schema for Validation

The following example creates domain w2\_form of type JSON with a constraint that checks that the value is a JSON object that complies with the provided JSON Schema. The check constraint uses IS JSON VALIDATE USING schema\_constant\_text:

```

CREATE DOMAIN w2_form AS JSON CONSTRAINT CHECK (VALUE IS JSON VALIDATE USING
'{'
    "title": "W2_form",
    "type": "object",

```

```
"properties": {
    "social_security_number": {
        "type": "string",
        "description": "The person social security number."
    },
    "wages": {
        "description": "total wages",
        "type": "number",
        "minimum": 0
    },
    "social_security_wages": {
        "type": "number",
        "description": "wages subject to social security tax"
    },
    "Federal Income Tax Withheld": {
        "type": "number",
        "description": "withheld of tax to federal income tax"
    },
    "Social Security Tax Withheld": {
        "type": "number",
        "description": "withheld of social security tax"
    }
},
"required": ["social_security_number", "wages", "Federal Income Tax Withheld"]
}';
```

The following statement creates table `tax_report` where column `w2_form` is associated with domain `w2_form` to ensure that its content conforms to the schema defined in the domain `w2_form`:

```
CREATE TABLE tax_report(id NUMBER, income JSON DOMAIN w2_form);
```

Before the data is inserted into the `income` column, it is checked against the JSON Schema. If the data is not valid, an error is raised.

Example of valid data:

```
INSERT INTO tax_report VALUES
(1, '{"wages": 100, "social_security_number": "111", "Federal Income Tax
Withheld":10}')
;
1 row created
```

Example of invalid data:

```
INSERT INTO tax_report VALUES
(2, '{"wages": 100}')
;
ERROR at line 1:
ORA-40875: JSON schema validation error
```

### Create a Domain Specifying a JSON Schema Using Shorthand Syntax

```
CREATE DOMAIN w2_form AS JSON VALIDATE USING
'{
    "title": "W2_form",
    "type": "object",
    "properties": {
```

```

"social_security_number": {
    "type": "string",
    "description": "The person social security number."
},
"wages": {
    "description": "total wages",
    "type": "number",
    "minimum": 0
},
"social_security_wages": {
    "type": "number",
    "description": "wages subject to social security tax"
},
"Federal Income Tax Withheld": {
    "type": "number",
    "description": "withheld of tax to federal income tax"
},
"Social Security Tax Withheld": {
    "type": "number",
    "description": "withheld of social security tax"
}
},
"required": ["social_security_number", "wages", "Federal Income Tax Withheld"]
}';

```

### **Example: Create a Domain with an Annotation Stored as JSON and Query its Value**

The following example creates a domain with an annotation `allowed_operations` specified as a JSON string which contains a nested JSON object:

```

CREATE DOMAIN email AS VARCHAR2(30)
    CONSTRAINT EMAIL_C CHECK (REGEXP_LIKE (email, '^(\S+)\@(\S+)\.(\S+)$'))
    DISPLAY '---' || SUBSTR(email, INSTR(email, '@') + 1)
    ANNOTATIONS (allowed_operations
'{
    "allowed_operations": {
        "title": "Allowed operations",
        "operations": [
            "Sort",
            "Group By",
            "Picklist"
        ]
    }
}');

```

Now you can run the following query to retrieve values for the annotation `allowed_operations`:

```

SELECT jt.* FROM user_annotations_usage,
JSON_TABLE(annotation_value, '$.allowed_operations.operations[*]')
COLUMNS (value VARCHAR2(50 CHAR) PATH '$') jt
WHERE annotation_name='ALLOWEDOPERATIONS';

```

The output is:

| VALUE |
|-------|
| ----- |

Sort  
Group By  
Picklist

### Example: Create a Domain with an Annotation Stored as JSON and Query its Value

The following example creates a domain with the annotation `display_units` specified as a JSON string containing an array to store the possible display units:

```
CREATE DOMAIN temperature AS NUMBER(3)
ANNOTATIONS (display_units '{ "units": ["celsius", "fahrenheit"] }');
```

Now you can query for the values of the annotation:

```
SELECT jt.* FROM user_annotations_usage,
JSON_TABLE(annotation_value, '$[*]')
COLUMNS (value VARCHAR2(30 CHAR) PATH '$')) jt
WHERE annotation_name='DISPLAYUNITS';
```

The output is:

| VALUE      |
|------------|
| celsius    |
| fahrenheit |

## CREATE EDITION

### Purpose

This statement creates a new edition as a child of an existing edition. An edition makes it possible to have two or more versions of the same editable objects in the database. When you create an edition, it immediately inherits all of the editable objects of its parent edition. The following object types are editable:

- Synonym
- View
- Function
- Procedure
- Package (specification and body)
- Type (specification and body)
- Library
- Trigger

An editable object is an object of one of the above editable object types in an editions-enabled schema. The ability to have multiple versions of these objects in the database greatly facilitates online application upgrades.

**Note:**

All database object types not listed above are not editionable. Changes to object types that are not editionable are immediately visible across all editions in the database.

Every newly created or upgraded Oracle Database has one default edition named ORA\$BASE, which serves as the parent of the first edition created with a CREATE EDITION statement. You can subsequently designate a user-defined edition as the database default edition using an ALTER DATABASE DEFAULT EDITION statement.

**See Also:**

- *Oracle Database Development Guide* for a more complete discussion of editionable object types and editions
- The ALTER DATABASE "DEFAULT EDITION Clause" for information on designating an edition as the default edition for the database

**Prerequisites**

To create an edition, you must have the CREATE ANY EDITION system privilege, granted either directly or through a role. To create an edition as a child of another edition, you must have the USE object privilege on the parent edition.

**Syntax**

*create\_edition::=*

**Semantics*****edition***

Specify the name of the edition to be created. The name must satisfy the requirements listed in "Database Object Naming Rules".

To view the editions that have been created for the database, query the EDITION\_NAME column of the DBA\_OBJECTS or ALL\_OBJECTS data dictionary view.

When you create an edition, the system automatically grants you the USE object privilege WITH GRANT OPTION on the edition you create.

 **Note:**

Oracle strongly recommends that you do not name editions with the prefixes ORA, ORACLE, SYS, DBA, and DBMS, as these prefixes are reserved for internal use.

**IF NOT EXISTS**

Specifying `IF NOT EXISTS` has the following effects:

- If the object does not exist, a new object is created at the end of the statement.
- If the object exists, this is the object you have at the end of the statement. A new one is not created because the older object is detected.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

**AS CHILD OF Clause**

If you use this clause, then the new edition is created as a child of `parent_edition`. If you omit this clause, then the new edition is created as a child of the leaf edition. At the time of its creation, the new edition inherits all editioned objects from its parent edition.

**Restriction on Editions**

An edition can have only one child edition. If you specify for `parent_edition` an edition that already has a child edition, then an error is returned.

**Examples**

The following very simple examples are intended to show the syntax for creating and working with an edition. For realistic examples of using editions refer to *Oracle Database Development Guide*.

In the following statements, the user `HR` is given the privileges needed to create and use an edition:

```
GRANT CREATE ANY EDITION, DROP ANY EDITION to HR;
Grant succeeded.
```

```
ALTER USER hr ENABLE EDITIONS;
User altered.
```

`HR` creates a new edition `TEST_ED` for testing purposes:

```
CREATE EDITION test_ed;
```

`HR` then creates an editioning view `ed_view` in the default edition `ORA$BASE` for testing purposes, first verifying that the current edition is the default edition:

```
SELECT SYS_CONTEXT('userenv', 'current_edition_name') FROM DUAL;
SYS_CONTEXT('USERENV','CURRENT_EDITION_NAME')
-----
ORA$BASE
1 row selected.
```

```
CREATE EDITIONING VIEW e_view AS
  SELECT last_name, first_name, email FROM employees;
```

View created.

```
DESCRIBE e_view
Name           Null?    Type
-----
LAST_NAME      NOT NULL VARCHAR2(25)
FIRST_NAME     VARCHAR2(20)
EMAIL          NOT NULL VARCHAR2(25)
```

The view is then actualized in the TEST\_ED edition when HR uses the TEST\_ED edition and re-creates the view in a different form:

```
ALTER SESSION SET EDITION = TEST_ED;
Session altered.
```

```
CREATE OR REPLACE EDITIONING VIEW e_view AS
SELECT last_name, first_name, email, salary FROM employees;
```

View created.

The view in the TEST\_ED edition has an additional column:

```
DESCRIBE e_view
Name           Null?    Type
-----
LAST_NAME      NOT NULL VARCHAR2(25)
FIRST_NAME     VARCHAR2(20)
EMAIL          NOT NULL VARCHAR2(25)
SALARY         NUMBER(8,2)
```

The view in the ORA\$BASE edition remains isolated from the test environment:

```
ALTER SESSION SET EDITION = ora$base;
Session altered.
```

```
DESCRIBE e_view;
```

```
Name           Null?    Type
-----
LAST_NAME      NOT NULL VARCHAR2(25)
FIRST_NAME     VARCHAR2(20)
EMAIL          NOT NULL VARCHAR2(25)
```

Even if the view is dropped in the test environment, it remains in the ORA\$BASE edition:

```
ALTER SESSION SET EDITION = TEST_ED;
Session altered.
```

```
DROP VIEW e_view;
View dropped.
```

```
ALTER SESSION SET EDITION = ORA$BASE;
Session altered.
```

```
DESCRIBE e_view
Name           Null?    Type
-----
LAST_NAME      NOT NULL VARCHAR2(25)
FIRST_NAME     VARCHAR2(20)
EMAIL          NOT NULL VARCHAR2(25)
```

When the testing of upgrade that necessitated the TEST\_ED edition is complete, the edition can be dropped:

```
DROP EDITION TEST_ED;
```

## CREATE FLASHBACK ARCHIVE

### Purpose

Use the CREATE FLASHBACK ARCHIVE statement to create a flashback archive, which provides the ability to automatically track and archive transactional data changes to specified database objects. A flashback archive consists of multiple tablespaces and stores historic data from all transactions against tracked tables. The data is stored in internal history tables.

Flashback data archives retain historical data for the time duration specified using the RETENTION parameter. Historical data can be queried using the Flashback Query AS OF clause. Archived historic data that has aged beyond the specified retention period is automatically purged.

Flashback data archives retain historical data across data definition language (DDL) changes to tables enabled for flashback archive. Flashback data archives supports many common DDL statements, including some DDL statements that alter table definitions or incur data movement. DDL statements that are not supported result in error ORA-55610.

### See Also:

- Oracle Database Development Guide for general information on using Flashback Time Travel
- The CREATE TABLE [flashback\\_archive\\_clause](#) for information on designating a table as a tracked table
- [ALTER FLASHBACK ARCHIVE](#) for information on changing the quota and retention attributes of the flashback archive, as well as adding or changing tablespace storage for the flashback archive

### Prerequisites

You must have the FLASHBACK ARCHIVE ADMINISTER system privilege to create a flashback archive. In addition, you must have the CREATE TABLESPACE system privilege to create a flashback archive, as well as sufficient quota on the tablespace in which the historical information will reside. To designate a flashback archive as the system default flashback archive, you must be logged in as SYSDBA.

## Syntax

***create\_flashback\_archive ::=***

***flashback\_archive\_quota ::=***

***flashback\_archive\_retention ::=***

## Semantics

### DEFAULT

You must be logged in as SYSDBA to specify DEFAULT. Use this clause to designate this flashback archive as the default flashback archive for the database. When a CREATE TABLE or ALTER TABLE statement specifies the *flashback\_archive\_clause* without specifying a flashback archive name, the database uses the default flashback archive to store data from that table.

You cannot specify this clause if a default flashback archive already exists. However, you can replace an existing default flashback archive using the ALTER FLASHBACK ARCHIVE ... SET DEFAULT clause.

#### See Also:

The CREATE TABLE *flashback\_archive\_clause* for more information

***flashback\_archive***

Specify the name of the flashback archive. The name must satisfy the requirements specified in "Database Object Naming Rules".

**TABLESPACE Clause**

Specify the tablespace where the archived data for this flashback archive is to be stored. You can specify only one tablespace with this clause. However, you can subsequently add tablespaces to the flashback archive with an ALTER FLASHBACK ARCHIVE statement.

***flashback\_archive\_quota***

Specify the amount of space in the initial tablespace to be reserved for the archived data. If the space for archiving in a flashback archive becomes full, then DML operations on tracked tables that use this flashback archive will fail. The database issues an out-of-space alert when the content of the flashback archive is 90% of the specified quota, to allow time to purge old data or add additional quota. If you omit this clause, then the flashback archive has unlimited quota on the specified tablespace.

**[NO] OPTIMIZE DATA**

Specify OPTIMIZE DATA to enable optimization for flashback archive history tables. This instructs the database to optimize the storage of data in history tables using any of the following features: Advanced Row Compression, Advanced LOB Compression, Advanced LOB Deduplication, segment-level compression tiering, and row-level compression tiering. To specify this clause, you must have a license for the Advanced Compression option.

Specify NO OPTIMIZE DATA to instruct the database not to optimize the storage of data in history tables. This is the default.

***flashback\_archive\_retention***

Specify the length of time in months, days, or years that the archived data should be retained in the flashback archive. If the length of time causes the flashback archive to become full, then the database responds as described in [\*flashback\\_archive\\_quota\*](#).

**Examples**

The following statement creates two flashback archives for testing purposes. The first is designated as the default for the database. For both of them, the space quota is 1 megabyte, and the archive retention is one day.

```
CREATE FLASHBACK ARCHIVE DEFAULT test_archive1
  TABLESPACE example
  QUOTA 1 M
  RETENTION 1 DAY;

CREATE FLASHBACK ARCHIVE test_archive2
  TABLESPACE example
  QUOTA 1 M
  RETENTION 1 DAY;
```

The next statement alters the default flashback archive to extend the retention period to 1 month:

```
ALTER FLASHBACK ARCHIVE test_archive1
  MODIFY RETENTION 1 MONTH;
```

The next statement specifies tracking for the oe.customers table. The flashback archive is not specified, so data will be archived in the default flashback archive, test\_archive1:

```
ALTER TABLE oe.customers
  FLASHBACK ARCHIVE;
```

The next statement specifies tracking for the oe.orders table. In this case, data will be archived in the specified flashback archive, test\_archive2:

```
ALTER TABLE oe.orders
  FLASHBACK ARCHIVE test_archive2;
```

The next statement drops test\_archive2 flashback archive:

```
DROP FLASHBACK ARCHIVE test_archive2;
```

## CREATE FUNCTION

### Purpose

Functions are defined in PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the CREATE FUNCTION statement to create a standalone stored function or a call specification.

- A **stored function** (also called a **user function** or **user-defined function**) is a set of PL/SQL statements you can call by name. Stored functions are very similar to procedures, except that a function returns a value to the environment in which it is called. User functions can be used as part of a SQL expression.
- A **call specification** declares a JavaScript method, a Java method or a third-generation language (3GL) routine so that it can be called from PL/SQL. You can also use the CALL SQL statement to call such a method or routine. The call specification tells Oracle Database which Java method, JavaScript method, or which named function in which shared library, to invoke when a call is made. It also tells the database what type conversions to make for the arguments and return value.

 **Note:**

You can also create a function as part of a package using the CREATE PACKAGE statement.

**See Also:**

- [CREATE PROCEDURE](#) for a general discussion of procedures and functions, [CREATE PACKAGE](#) for information on creating packages, [ALTER FUNCTION](#) and [DROP FUNCTION](#) for information on modifying and dropping a function
- [CREATE LIBRARY](#) for information on shared libraries
- *Oracle Database Development Guide* for more information about registering external functions
- *JavaScript Developer's Guide*
- [CREATE MLE MODULE](#)

**Prerequisites**

To create or replace a function in your own schema, you must have the `CREATE PROCEDURE` system privilege. To create or replace a function in another user's schema, you must have the `CREATE ANY PROCEDURE` system privilege.

**Syntax**

Functions are defined using PL/SQL. Alternatively they can refer to non-PL/SQL code such as Java, JavaScript, C, and others by means of call specifications. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

***create\_function ::=***

(*plsql\_function\_source*: See *Oracle Database PL/SQL Language Reference*.)

**Semantics****OR REPLACE**

Specify `OR REPLACE` to re-create the function if it already exists. Use this clause to change the definition of an existing function without dropping, re-creating, and regranting object privileges previously granted on the function. If you redefine a function, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined function can still access the function without being regranted the privileges.

If any function-based indexes depend on the function, then Oracle Database marks the indexes `DISABLED`.

 **See Also:**

[ALTER FUNCTION](#) for information on recompiling functions using SQL

## IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the function does not exist, a new function is created at the end of the statement.
- If the function exists, this is the function you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

### [ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the function is an editioned or noneditioned object if editioning is enabled for the schema object type `FUNCTION` in *schema*. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

### `plsql_function_source`

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the `plsql_function_source`, including examples.

# CREATE HIERARCHY

## Purpose

Use the `CREATE HIERARCHY` statement to create a hierarchy. A hierarchy specifies the hierarchical relationships among the levels of an attribute dimension.

## Prerequisites

To create a hierarchy in your own schema, you must have the `CREATE HIERARCHY` system privilege. To create a hierarchy in another user's schema, you must have the `CREATE ANY HIERARCHY` system privilege.

## Syntax

*create\_hierarchy ::=*

*classification\_clause ::=*

*hier\_using\_clause ::=*

*level\_hier\_clause ::=*

*hierAttrsClause ::=*

***hier\_attr\_clause ::=***

***hier\_attr\_name ::=***

### Semantics

#### OR REPLACE

Specify `OR REPLACE` to replace an existing definition of a hierarchy with a different definition.

#### FORCE and NOFORCE

Specify `FORCE` to force the creation of the hierarchy even if it does not successfully compile. If you specify `NOFORCE`, then the hierarchy must compile successfully, otherwise an error occurs. The default is `NOFORCE`.

#### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the hierarchy does not exist, a new hierarchy is created at the end of the statement.
- If the hierarchy exists, this is the hierarchy you have at the end of the statement. A new one is not created because the older one is detected.

You can have **one of** `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: `ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement`.

Using IF EXISTS with CREATE results in ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.

### ***schema***

Specify the schema in which to create the hierarchy. If you do not specify a schema, then Oracle Database creates the hierarchy in your own schema.

### ***hierarchy***

Specify a name for the hierarchy.

### **SHARING**

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- METADATA - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- NONE - The object is not shared and can only be accessed in the application root.

### ***classification\_clause***

Use the classification clause to specify values for the CAPTION or DESCRIPTION classifications and to specify user-defined classifications. Classifications provide descriptive metadata that applications may use to provide information about analytic views and their components.

You may specify any number of classifications for the same object. A classification can have a maximum length of 4000 bytes.

For the CAPTION and DESCRIPTION classifications, you may use the DDL shortcuts CAPTION 'caption' and DESCRIPTION 'description' or the full classification syntax.

You may vary the classification values by language. To specify a language for the CAPTION or DESCRIPTION classification, you must use the full syntax. If you do not specify a language, then the language value for the classification is NULL. The language value must either be NULL or a valid NLS\_LANGUAGE value.

### ***hier\_using\_clause***

Specify the attribute dimension that has the members of the hierarchy.

### ***level\_hier\_clause***

Specify the organization of the hierarchy levels.

### ***hierAttrs\_clause***

Specify classifications that contain descriptive metadata for the hierarchical attributes. A *hier\_attr\_clause* for a given *hier\_attr\_name* may appear only once in the list.

All hierarchies always contain all of the hierarchical attributes, but a hierarchical attribute does not have descriptive metadata associated with it unless you specify it with this clause.

***hier\_attr\_clause***

Specify a hierarchical attribute and provide one or more classifications for it.

***hier\_attr\_name***

Specify a hierarchical attribute.

**Examples**

The following example creates the TIME\_HIER hierarchy:

```
CREATE OR REPLACE HIERARCHY time_hier -- Hierarchy name
USING time_attr_dim          -- Refers to TIME_ATTR_DIM attribute
dimension
  (month CHILD OF           -- Months in the attribute dimension
   quarter CHILD OF
   year);
```

The following example creates the PRODUCT\_HIER hierarchy:

```
CREATE OR REPLACE HIERARCHY product_hier
USING product_attr_dim
  (category
   CHILD OF department);
```

The following example creates the GEOGRAPHY\_HIER hierarchy:

```
CREATE OR REPLACE HIERARCHY geography_hier
USING geography_attr_dim
  (state_province
   CHILD OF country
   CHILD OF region);
```

## CREATE INDEX

**Purpose**

Use the CREATE INDEX statement to create an index on:

- One or more columns of a table, a partitioned table, an index-organized table, or a cluster
- One or more scalar typed object attributes of a table or a cluster
- A nested table storage table for indexing a nested table column

An **index** is a schema object that contains an entry for each value that appears in the indexed column(s) of the table or cluster and provides direct, fast access to rows. The maximum size of a single index entry is dependent on the block size of the database.

Oracle Database supports several types of index:

- **Normal indexes.** (By default, Oracle Database creates B-tree indexes.)

- **Bitmap indexes**, which store rowids associated with a key value as a bitmap.
- **Partitioned indexes**, which consist of partitions containing an entry for each value that appears in the indexed column(s) of the table.
- **Function-based indexes**, which are based on expressions. They enable you to construct queries that evaluate the value returned by an expression, which in turn may include built-in or user-defined functions.
- **Domain indexes**, which are instances of an application-specific index of type *indextype*.

 **Note:**

- *Oracle Database Concepts* for a discussion of indexes
- *Oracle Database Reference* for more information about the limits related to index size
- *Oracle Database Reference* for information on how index creation inherits compression attributes
- [ALTER INDEX](#) and [DROP INDEX](#)

### Prerequisites

To create an index in your own schema, one of the following conditions must be true:

- The table or cluster to be indexed must be in your own schema.
- You must have the `INDEX` object privilege on the table to be indexed.
- You must have the `CREATE ANY INDEX` system privilege.

To create an index in another schema, you must have the `CREATE ANY INDEX` system privilege. Also, the owner of the schema to contain the index must have either the `UNLIMITED TABLESPACE` system privilege or space quota on the tablespaces to contain the index or index partitions.

To create a function-based index, in addition to the prerequisites for creating a conventional index, if the index is based on user-defined functions, then those functions must be marked `DETERMINISTIC`. A function-based index is executed with the credentials of the index owner, so the index owner must have the `EXECUTE` object privilege on the function.

To create a domain index in your own schema, in addition to the prerequisites for creating a conventional index, you must also have the `EXECUTE` object privilege on the *indextype*. If you are creating a domain index in another user's schema, then the index owner also must have the `EXECUTE` object privilege on the *indextype* and its underlying implementation type. Before creating a domain index, you should first define the *indextype*.

## Semantics

### UNIQUE

Specify `UNIQUE` to indicate that the value of the column (or columns) upon which the index is based must be unique.

#### Restrictions on Unique Indexes

Unique indexes are subject to the following restrictions:

- You cannot specify both `UNIQUE` and `BITMAP`.
- You cannot specify `UNIQUE` for a domain index.

#### See Also:

"[Unique Constraints](#)" for information on the conditions that satisfy a unique constraint

### BITMAP

Specify `BITMAP` to indicate that `index` is to be created with a bitmap for each distinct key, rather than indexing each row separately. Bitmap indexes store the rowids associated with a key value as a bitmap. Each bit in the bitmap corresponds to a possible rowid. If the bit is set, then it means that the row with the corresponding rowid contains the key value. The internal representation of bitmaps is best suited for applications with low levels of concurrent transactions, such as data warehousing.

#### Note:

Oracle does not index table rows in which all key columns are null except in the case of bitmap indexes. Therefore, if you want an index on all rows of a table, then you must either specify `NOT NULL` constraints for the index key columns or create a bitmap index.

#### Restrictions on Bitmap Indexes

Bitmap indexes are subject to the following restrictions:

- You cannot specify `BITMAP` when creating a global partitioned index.
- You cannot create a bitmap secondary index on an index-organized table unless the index-organized table has a mapping table associated with it.
- You cannot specify both `UNIQUE` and `BITMAP`.
- You cannot specify `BITMAP` for a domain index.
- A bitmap index can have a maximum of 30 columns.

 See Also:

- Oracle Database Concepts and Oracle Database SQL Tuning Guide for more information about using bitmap indexes
- [CREATE TABLE](#) for information on mapping tables
- "Bitmap Index Examples"

**MULTIValue**

Use the `MULTIValue` keyword to create a multivalue index on JSON data using simple dot-notation syntax to specify the path to the indexed data.

**Example**

The multivalue index created here indexes the values of top-level field `credit_score`. If the `credit_score` value targeted by a query is an array, then the index can be picked up for any array elements that are numbers. If the value is a scalar, then the index can be picked up if the scalar is a number.

```
CREATE MULTIVALEUE INDEX mvi_1 ON mytable
  (t.jcol.credit_score.numberOnly());
```

 See Also:

- Indexes for JSON Data
- Simple Dot-Notation Access to JSON Data

**IF NOT EXISTS**

Specifying `IF NOT EXISTS` has the following effects:

- If the index does not exist, a new index is created at the end of the statement.
- If the index exists, this is the index you have at the end of the statement. A new one is not created because the older index is detected.

Using `IF EXISTS` with `CREATE INDEX` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

***schema***

Specify the schema to contain the index. If you omit `schema`, then Oracle Database creates the index in your own schema.

***index\_name***

Specify the name of the index to be created. The name must satisfy the requirements listed in [Database Object Naming Rules](#).

 See Also:

[Creating an Index: Example](#) and [Creating an Index on an XMLType Table: Example](#)

***index\_ilm\_clause***

With Oracle Database Release 20c you can use the *index\_ilm\_clause* to add or delete an ILM policy to an index.

You can also add an ILM policy to an index after you create it with the `ALTER INDEX` statement.

When you create an index with an ILM policy, you can add only one new policy. To add more policies to an index, or to modify existing policies on the index you must use the `ALTER INDEX` statement.

You cannot modify an ILM policy at the index partition level. The index level modification will be cascaded to all partitions.

**Examples**

```
CREATE INDEX [schema.]empno_idx ILM_POLICY
```

**Restrictions**

You cannot add an ILM policy on cluster indexes and IOTs.

You cannot add an ILM policy on domain indexes and bitmap indexes.

***policy\_clause***

The `OPTIMIZE` index policy chooses the appropriate action if the policy condition is met.

You can create ILM policies on objects in the same schema.

If you want to move the ILM policy to a different tablespace, you must ensure that you have the necessary permissions for all the tablespaces mentioned in the ILM policy.

You must also ensure that you have the necessary storage on the target tablespaces for storage tiering jobs.

***cluster\_index\_clause***

Use the *cluster\_index\_clause* to identify the cluster for which a cluster index is to be created. If you do not qualify cluster with *schema*, then Oracle Database assumes the cluster is in your current schema. You cannot create a cluster index for a hash cluster.

 See Also:

[CREATE CLUSTER](#) and "Creating a Cluster Index: Example"

***table\_index\_clause***

Specify the table on which you are defining the index. If you do not qualify *table* with *schema*, then Oracle Database assumes the table is contained in your own schema.

You create an index on a nested table column by creating the index on the nested table storage table. Include the `NESTED_TABLE_ID` pseudocolumn of the storage table to create a `UNIQUE` index, which effectively ensures that the rows of a nested table value are distinct.

 **See Also:**

["Indexes on Nested Tables: Example"](#)

You can perform DDL operations (such as `ALTER TABLE`, `DROP TABLE`, `CREATE INDEX`) on a temporary table only when no session is bound to it. A session becomes bound to a temporary table by performing an `INSERT` operation on the table. A session becomes unbound to the temporary table by issuing a `TRUNCATE` statement or at session termination, or, for a transaction-specific temporary table, by issuing a `COMMIT` or `ROLLBACK` statement.

**Restrictions on the *table\_index\_clause***

This clause is subject to the following restrictions:

- If *index* is locally partitioned, then *table* must be partitioned.
- If *table* is index-organized, then this statement creates a secondary index. The index contains the index key and the logical rowid of the index-organized table. The logical rowid excludes columns that are also part of the index key. You cannot specify `REVERSE` for this secondary index, and the combined size of the index key and the logical rowid should be less than the block size.
- If *table* is a temporary table, then *index* will also be temporary with the same scope (session or transaction) as *table*. The following restrictions apply to indexes on temporary tables:
  - The only part of *index\_properties* you can specify is *index\_attributes*.
  - Within *index\_attributes*, you cannot specify the *physical\_attributes\_clause*, the *parallel\_clause*, the *logging\_clause*, or *TABLESPACE*.
  - You cannot create a domain index or a partitioned index on a temporary table.
- You cannot create an index on an external table.

 **See Also:**

[CREATE TABLE](#) and *Oracle Database Concepts* for more information on temporary tables

### ***t\_alias***

Specify a correlation name (alias) for the table upon which you are building the index.

#### Note:

This alias is required if the *index\_expr* references any object type attributes or object type methods. See "[Creating a Function-based Index on a Type Method: Example](#)" and "[Indexing on Substitutable Columns: Examples](#)".

### ***index\_expr***

For *index\_expr*, specify the column or column expression upon which the index is based.

You can create multiple indexes on the same set of columns, column expressions, or both if the following conditions are met:

- The indexes are of different types, use different partitioning, or have different uniqueness properties.
- Only one of the indexes is **VISIBLE** at any given time.

#### See Also:

*Oracle Database Administrator's Guide* for more information on creating multiple indexes

### ***column***

Specify the name of one or more columns in the table. A bitmap index can have a maximum of 30 columns. Other indexes can have as many as 32 columns. These columns define the **index key**.

If a unique index is local nonprefixed (see [local\\_partitioned\\_index](#)), then the index key must contain the partitioning key.

#### See Also:

*Oracle Database VLDB and Partitioning Guide* for information on prefixed and nonprefixed indexes

You can create an index on a scalar object attribute column or on the system-defined NESTED\_TABLE\_ID column of the nested table storage table. If you specify an object attribute column, then the column name must be qualified with the table name. If you specify a nested table column attribute, then it must be qualified with the outermost table name, the containing column name, and all intermediate attribute names leading to the nested table column attribute.

When you create an index on a column or expression with a declared or derived named collation other than `BINARY`, or a declared or derived pseudo-collation `USING_NLS_SORT_CI` or `USING_NLS_SORT_AI`, the database creates a functional index on the function `NLSSORT`. See *Oracle Database Globalization Support Guide* for more information.

### Creating an Index on an Extended Data Type Column

If `column` is an extended data type column, then you may receive a "maximum key length exceeded" error when attempting to create the index. The maximum key length for an index varies depending on the database block size and some additional index metadata stored in a block. For example, for databases that use the Oracle standard 8K block size, the maximum key length is approximately 6400 bytes.

To work around this situation, you must shorten the length of the values you want to index, using one of the following methods:

- Create a function-based index to shorten the values stored in the extended data type column as part of the expression used for the index definition.
- Create a virtual column to shorten the values stored in the extended data type column as part of the expression used for the virtual column definition and build a normal index on the virtual column. Using a virtual column also enables you to leverage functionality for regular columns, such as collecting statistics and using constraint and triggers.

For both methods you can use either the `SUBSTR` or `STANDARD_HASH` function to shorten the values of the extended data type column to build an index. These methods have the following advantages and disadvantages:

- Use the `SUBSTR` function to return a substring, or prefix, of `column` that is an acceptable length for the index key. This type of index can be used for equality, IN-list, and range predicates on the original column without the need to specify the `SUBSTR` column as part of the predicate. Refer to `SUBSTR` for more information.
- Using the `STANDARD_HASH` function is likely to create an index that is more compact than the substring-based index and may result in fewer unnecessary index accesses. This type of index can be used for equality and IN-list predicates on the original column without the need to specify the `STANDARD_HASH` column as part of the predicate. Refer to `STANDARD_HASH` for more information.

The following example shows how to create a function-based index on an extended data type column:

```
CREATE INDEX index ON table (SUBSTR(column, 1, n));
```

For `n`, specify a prefix length that is large enough to differentiate between values in `column`.

The following example shows how to create a virtual column for an extended data type column, and then create an index on the virtual column:

```
ALTER TABLE table ADD (new_hash_column AS (STANDARD_HASH(column)));
CREATE INDEX index ON table (new_hash_column);
```

 See Also:

["Extended Data Types"](#) for more information on extended data types

### Restrictions on Index Columns

The following restrictions apply to index columns:

- You cannot create an index on columns or attributes whose type is user-defined, `LONG`, `LONG RAW`, `LOB`, or `REF`, except that Oracle Database supports an index on `REF` type columns or attributes that have been defined with a `SCOPE` clause.
- Only normal (B-tree) indexes can be created on encrypted columns, and they can only be used for equality searches.

#### *column\_expression*

Specify an expression built from columns of `table`, constants, SQL functions, and user-defined functions. When you specify `column_expression`, you create a **function-based index**.

 See Also:

["Column Expressions "](#), ["Notes on Function-based Indexes"](#), ["Restrictions on Function-based Indexes"](#), and ["Function-Based Index Examples"](#)

Name resolution of the function is based on the schema of the index creator. User-defined functions used in `column_expression` are fully name resolved during the `CREATE INDEX` operation.

After creating a function-based index, collect statistics on both the index and its base table using the `DBMS_STATS` package. Such statistics will enable Oracle Database to correctly decide when to use the index.

Function-based unique indexes can be useful in defining a conditional unique constraint on a column or combination of columns. Refer to ["Using a Function-based Index to Define Conditional Uniqueness: Example"](#) for an example.

 See Also:

[Oracle Database PL/SQL Packages and Types Reference](#) for more information on the `DBMS_STATS` package

### Notes on Function-based Indexes

The following notes apply to function-based indexes:

- When you subsequently query a table that uses a function-based index, Oracle Database will not use the index unless the query filters out nulls. However, Oracle Database will use a function-based index in a query even if the columns specified in the `WHERE` clause

are in a different order than their order in the *column\_expression* that defined the function-based index.

 **See Also:**

"[Function-Based Index Examples](#)"

- If the function on which the index is based becomes invalid or is dropped, then Oracle Database marks the index DISABLED. Queries on a DISABLED index fail if the optimizer chooses to use the index. DML operations on a DISABLED index fail unless the index is also marked UNUSABLE **and** the parameter SKIP\_UNUSABLE\_INDEXES is set to true. Refer to [ALTER SESSION](#) for more information on this parameter.
- If a public synonym for a function, package, or type is used in *column\_expression*, and later an actual object with the same name is created in the table owner's schema, then Oracle Database disables the function-based index. When you subsequently enable the function-based index using ALTER INDEX ... ENABLE or ALTER INDEX ... REBUILD, the function, package, or type used in the *column\_expression* continues to resolve to the function, package, or type to which the public synonym originally pointed. It will not resolve to the new function, package, or type.
- If the definition of a function-based index generates internal conversion to character data, then use caution when changing NLS parameter settings. Function-based indexes use the current database settings for NLS parameters. If you reset these parameters at the session level, then queries using the function-based index may return incorrect results. Two exceptions are the collation parameters (NLS\_SORT and NLS\_COMP). Oracle Database handles the conversions correctly even if these have been reset at the session level.
- Oracle Database cannot convert data in all cases, even when conversion is explicitly requested. For example, an attempt to convert the string '105 lbs' from VARCHAR2 to NUMBER using the TO\_NUMBER function fails with an error. Therefore, if *column\_expression* contains a data conversion function such as TO\_NUMBER or TO\_DATE, and if a subsequent INSERT or UPDATE statement includes data that the conversion function cannot convert, then the index will cause the INSERT or UPDATE statement to fail.
- If *column\_expression* contains a datetime format model, then the function-based index expression defining the column may contain format elements that are different from those specified. For example, define a function-based index using the yyyy datetime format element:

```
CREATE INDEX cust_eff_ix ON customers
  (NVL(cust_eff_to, TO_DATE('9000-01-01 00:00:00', 'yyyy-mm-dd
hh24:mi:ss')));
```

Query the ALL\_IND\_EXPRESSIONS view to see that the function-based index expression defining the column uses the syyyy datetime format element:

```
SELECT column_expression
  FROM all_ind_expressions
 WHERE index_name='CUST_EFF_IX';

COLUMN_EXPRESSION
```

```
-----  
NVL("CUST_EFF_TO",TO_DATE(' 9000-01-01 00:00:00', 'syyyy-mm-dd hh24:mi:ss'))
```

### Restrictions on Function-based Indexes

Function-based indexes are subject to the following restrictions:

- The value returned by the function referenced in *column\_expression* is subject to the same restrictions as are the index columns of a B-tree index. Refer to "Restrictions on Index Columns".
- Any user-defined function referenced in *column\_expression* must be declared as DETERMINISTIC.
- For a function-based globally partitioned index, the *column\_expression* cannot be the partitioning key.
- The *column\_expression* can be any of the forms of expression described in Column Expressions .
- All functions must be specified with parentheses, even if they have no parameters. Otherwise Oracle Database interprets them as column names.
- Any function you specify in *column\_expression* must return a repeatable value. For example, you cannot specify the SYSDATE or USER function or the ROWNUM pseudocolumn.

 **See Also:**

[CREATE FUNCTION](#) and *Oracle Database PL/SQL Language Reference*

### ASC | DESC

Use `ASC` or `DESC` to indicate whether the index should be created in ascending or descending order. Indexes on character data are created in ascending or descending order of the character values in the database character set.

Oracle Database treats descending indexes as if they were function-based indexes. As with other function-based indexes, the database does not use descending indexes until you first analyze the index and the table on which the index is defined. See the *column\_expression* clause of this statement.

Ascending unique indexes allow multiple `NULL` values. However, in descending unique indexes, multiple `NULL` values are treated as duplicate values and therefore are not permitted.

### Restriction on Ascending and Descending Indexes

You cannot specify either of these clauses for a domain index. You cannot specify `DESC` for a reverse index. Oracle Database ignores `DESC` if *index* is bitmapped or if the `COMPATIBLE` initialization parameter is set to a value less than 8.1.0.

#### ***index\_attributes***

Specify the optional index attributes.

#### ***physical\_attributes\_clause***

Use the *physical\_attributes\_clause* to establish values for physical and storage characteristics for the index.

If you omit this clause, then Oracle Database sets `PCTFREE` to 10 and `INITTRANS` to 2.

### Restriction on Index Physical Attributes

You cannot specify the `PCUSED` parameter for an index.

#### See Also:

[physical\\_attributes\\_clause](#) and [storage\\_clause](#) for a complete description of these clauses

## TABLESPACE

For `tablespace`, specify the name of the tablespace to hold the index, index partition, or index subpartition. If you omit this clause, then Oracle Database creates the index in the default tablespace of the owner of the schema containing the index.

For a local index, you can specify the keyword `DEFAULT` in place of `tablespace`. New partitions or subpartitions added to the local index will be created in the same tablespace(s) as the corresponding partitions or subpartitions of the underlying table.

### *index\_compression*

The `index_compression` clauses let you enable or disable index compression for the index. Specify the `COMPRESS` clause of `prefix_compression` to enable prefix compression for the index, specify the `COMPRESS ADVANCED` clause of `advanced_index_compression` to enable advanced index compression for the index, or specify the `NOCOMPRESS` clause of either `prefix_compression` or `advanced_index_compression` to disable compression for the index. The default is `NOCOMPRESS`.

If you want to use compression for a partitioned index, then you must create the index with compression enabled at the index level. You can subsequently enable and disable the compression setting for individual partitions of such a partitioned index. You can also enable and disable compression when rebuilding individual partitions. You can modify an existing nonpartitioned index to enable or disable compression only when rebuilding the index.

### *prefix\_compression*

Specify `COMPRESS` to enable **prefix compression**, also known as key compression, which eliminates repeated occurrence of key column values. Use `integer` to specify the prefix length (number of prefix columns to compress). You can specify prefix compression for indexes that are nonunique or unique indexes of at least two columns.

- For unique indexes, the range of valid prefix length values is from 1 to the number of key columns minus 1. The default prefix length is the number of key columns minus 1.
- For nonunique indexes, the range of valid prefix length values is from 1 to the number of key columns. The default prefix length is the number of key columns.

### *advanced\_index\_compression*

Specify this clause to enable **advanced index compression**. Advanced index compression improves compression ratios significantly while still providing efficient

access to indexes. Therefore, advanced index compression works well on all supported indexes, including those indexes that are not good candidates for prefix compression.

- COMPRESS ADVANCED LOW - This level compresses the index less than the HIGH level, but provides faster access to the index. You can specify this clause for indexes that are nonunique or unique indexes of at least two columns. Before enabling COMPRESS ADVANCED LOW, the database must be at 12.1.0 or higher compatibility level.
- COMPRESS ADVANCED HIGH - This level compresses the index more than the LOW level, but provides slower access to the index. You can specify this clause for indexes that are nonunique or unique indexes of one or more columns. Before enabling COMPRESS ADVANCED HIGH, the database must be at 12.2.0 or higher compatibility level.

If you omit the LOW and HIGH keywords, then the default is HIGH.

### Restrictions on Index Compression

The following restrictions apply to index compression:

- You cannot specify prefix compression or advanced index compression for a bitmap index.
- You cannot specify advanced index compression for index-organized tables.

#### See Also:

- DB\_INDEX\_COMPRESSION\_INHERITANCE for more on how index creation inherits compression attributes
- *Oracle Database Administrator's Guide* for more information on prefix compression and advanced index compression
- "[Compressing an Index: Example](#)"

### *partial\_index\_clause*

You can specify this clause only when creating an index on a partitioned table. Specify INDEXING FULL to create a **full index**. Specify INDEXING PARTIAL to create a **partial index**. The default is INDEXING FULL.

A full index includes all partitions in the underlying table, regardless of their indexing properties. A partial index includes only partitions in the underlying table with an indexing property of ON.

If a partial index is a local partitioned index, then index partitions that correspond with table partitions with an indexing property of ON are marked USABLE. Index partitions that correspond with table partitions with an indexing property of OFF are marked UNUSABLE.

If the underlying table is a composite-partitioned table, then the preceding conditions for index partitions and table partitions apply instead to index subpartitions and table subpartitions.

### Restrictions on Partial Indexes

Partial indexes are subject to the following restrictions:

- The underlying table of a partial index cannot be a nonpartitioned table.

- Unique indexes cannot be partial indexes. This applies to indexes created with the CREATE UNIQUE INDEX statement and indexes that are implicitly created when you specify a unique constraint on one or more columns.

 **See Also:**

CREATE TABLE *indexing\_clause* for information on the indexing property

### SORT | NOSORT

By default, Oracle Database sorts indexes in ascending order when it creates the index. You can specify `NOSORT` to indicate to the database that the rows are already stored in the database in ascending order, so that Oracle Database does not have to sort the rows when creating the index. If the rows of the indexed column or columns are not stored in ascending order, then the database returns an error. For greatest savings of sort time and space, use this clause immediately after the initial load of rows into a table. If you specify neither of these keywords, then `SORT` is the default.

#### Restrictions on NOSORT

This parameter is subject to the following restrictions:

- You cannot specify `REVERSE` with this clause.
- You cannot use this clause to create a cluster index partitioned or bitmap index.
- You cannot specify this clause for a secondary index on an index-organized table.

### REVERSE

Specify `REVERSE` to store the bytes of the index block in reverse order, excluding the `rowid`.

#### Restrictions on Reverse Indexes

Reverse indexes are subject to the following restrictions:

- You cannot specify `NOSORT` with this clause.
- You cannot reverse a bitmap index or an index on an index-organized table.

### VISIBLE | INVISIBLE

Use this clause to specify whether the index is visible or invisible to the optimizer. An invisible index is maintained by DML operations, but it is not used by the optimizer during queries unless you explicitly set the parameter `OPTIMIZER_USE_INVISIBLE_INDEXES` to `TRUE` at the session or system level.

To determine whether an existing index is visible or invisible to the optimizer, you can query the `VISIBILITY` column of the `USER_`, `DBA_`, `ALL_INDEXES` data dictionary views.

 **See Also:**

*Oracle Database Administrator's Guide* for more information on this feature

### *logging\_clause*

Specify whether the creation of the index will be logged (LOGGING) or not logged (NOLOGGING) in the redo log file. This setting also determines whether subsequent Direct Loader (SQL\*Loader) and direct-path `INSERT` operations against the index are logged or not logged. LOGGING is the default.

If `index` is nonpartitioned, then this clause specifies the logging attribute of the index.

If `index` is partitioned, then this clause determines:

- The default value of all partitions specified in the `CREATE` statement, unless you specify the *logging\_clause* in the `PARTITION` description clause
- The default value for the segments associated with the index partitions
- The default value for local index partitions or subpartitions added implicitly during subsequent `ALTER TABLE ... ADD PARTITION` operations

The logging attribute of the index is independent of that of its base table.

If you omit this clause, then the logging attribute is that of the tablespace in which it resides.

#### See Also:

- [logging\\_clause](#) for a full description of this clause
- *Oracle Database VLDB and Partitioning Guide* for more information about logging and parallel DML
- ["Creating an Index in NOLOGGING Mode: Example"](#)

### ONLINE

Specify `ONLINE` to indicate that DML operations on the table will be allowed during creation of the index.

#### Restrictions on Online Index Building

Online index building is subject to the following restrictions:

- Parallel DML is not supported during online index building. If you specify `ONLINE` and then issue parallel DML statements, then Oracle Database returns an error.
- You can specify `ONLINE` for a bitmap index or a cluster index as long as you set `COMPATIBLE` to 10 or higher.
- You cannot specify `ONLINE` for a conventional index on a `UROWID` column.
- For a nonunique secondary index on an index-organized table, the number of index key columns plus the number of primary key columns that are included in the logical rowid in the index-organized table cannot exceed 32. The logical rowid excludes columns that are part of the index key.

 **See Also:**

*Oracle Database Concepts* for a description of online index building and rebuilding

#### ***parallel\_clause***

Specify the *parallel\_clause* if you want creation of the index to be parallelized.

For complete information on this clause, refer to [parallel\\_clause](#) in the documentation on CREATE TABLE.

#### **Index Partitioning Clauses**

Use the *global\_partitioned\_index* clause and the *local\_partitioned\_index* clauses to partition *index*.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to *Oracle Database VLDB and Partitioning Guide* for a discussion of these restrictions.

 **See Also:**

"[Partitioned Index Examples](#)"

#### ***annotations\_clause***

For the full semantics of the annotations clause see [annotations\\_clause](#).

#### ***global\_partitioned\_index***

The *global\_partitioned\_index* clause lets you specify that the partitioning of the index is user defined and is not equipartitioned with the underlying table. By default, nonpartitioned indexes are global indexes.

You can partition a global index by range or by hash. In both cases, you can specify up to 32 columns as partitioning key columns. The partitioning column list must specify a left prefix of the index column list. If the index is defined on columns a, b, and c, then for the columns you can specify (a, b, c), or (a, b), or (a, c), but you cannot specify (b, c) or (c) or (b, a). If you specify a partition name, then it must conform to the rules for naming schema objects and their parts as described in "[Database Object Naming Rules](#)". If you omit the partition names, then Oracle Database assigns names of the form *SYS\_Pn*.

#### **GLOBAL PARTITION BY RANGE**

Use this clause to create a range-partitioned global index. Oracle Database will partition the global index on the ranges of values from the table columns you specify in the column list.

 See Also:

"[Creating a Range-Partitioned Global Index: Example](#)"

### GLOBAL PARTITION BY HASH

Use this clause to create a hash-partitioned global index. Oracle Database assigns rows to the partitions using a hash function on values in the partitioning key columns.

 See Also:

The CREATE TABLE clause *hash\_partitions* for information on the two methods of hash partitioning and "[Creating a Hash-Partitioned Global Index: Example](#)"

### Restrictions on Global Partitioned Indexes

Global partitioned indexes are subject to the following restrictions:

- The partitioning key column list cannot contain the `ROWID` pseudocolumn or a column of type `ROWID`.
- The only property you can specify for hash partitions is tablespace storage. Therefore, you cannot specify LOB or varray storage clauses in the *partitioning\_storage\_clause* of *individual\_hash\_partitions*.
- You cannot specify the `OVERFLOW` clause of *hash\_partitions\_by\_quantity*, as that clause is valid only for index-organized table partitions.
- In the *partitioning\_storage\_clause*, you cannot specify `table_compression` or the `inmemory_clause`, but you can specify `index_compression`.

 Note:

If your enterprise has or will have databases using different character sets, then use caution when partitioning on character columns. The sort sequence of characters is not identical in all character sets.

 See Also:

*Oracle Database Globalization Support Guide* for more information on character set support

### *index\_partitioning\_clause*

Use this clause to describe the individual index partitions. The number of repetitions of this clause determines the number of partitions. If you omit *partition*, then Oracle Database generates a name with the form `SYS_Pn`.

For `VALUES LESS THAN (value_list)`, specify the noninclusive upper bound for the current partition in a global index. The value list is a comma-delimited, ordered list of literal values corresponding to the column list in the `global_partitioned_index` clause. Always specify `MAXVALUE` as the value of the last partition.

 **Note:**

If the index is partitioned on a `DATE` column, and if the date format does not specify the first two digits of the year, then you must use the `TO_DATE` function with a 4-character format mask for the year. The date format is determined implicitly by `NLS_TERRITORY` or explicitly by `NLS_DATE_FORMAT`. Refer to *Oracle Database Globalization Support Guide* for more information on these initialization parameters.

 **See Also:**

"[Range Partitioning Example](#)"

### ***local\_partitioned\_index***

The `local_partitioned_index` clauses let you specify that the index is partitioned on the same columns, with the same number of partitions and the same partition bounds as `table`. For composite-partitioned tables, this clause lets you specify that the index is subpartitioned on the same columns, with the same number of subpartitions and the same subpartition bounds as `table`. Oracle Database automatically maintains local index partitioning as the underlying table is repartitioned.

If you specify only the keyword `LOCAL` and do not specify a subclause, then Oracle Database creates each index partition in the same tablespace as its corresponding table partition and assigns it the same name as its corresponding table partition. If `table` is a composite-partitioned table, then Oracle Database creates each index subpartition in the same tablespace as its corresponding table subpartition and assigns it the same name as its corresponding table subpartition.

If you specify a partition name, then it must conform to the rules for naming schema objects and their parts as described in "[Database Object Naming Rules](#)". If you omit a partition name, then Oracle Database generates a name that is consistent with the corresponding table partition. If the name conflicts with an existing index partition name, then the database uses the form `SYS_Pn`.

### ***on\_range\_partitioned\_table***

This clause lets you specify the names and attributes of index partitions on a range-partitioned table. If you specify this clause, then the number of `PARTITION` clauses must be equal to the number of table partitions, and in the same order.

You cannot specify prefix compression for an index partition unless you have specified prefix compression for the index.

For more information on the `USABLE` and `UNUSABLE` clauses, refer to [USABLE | UNUSABLE](#).

***on\_list\_partitioned\_table***

The *on\_list\_partitioned\_table* clause is identical to [on\\_range\\_partitioned\\_table](#).

***on\_hash\_partitioned\_table***

This clause lets you specify names and tablespace storage for index partitions on a hash-partitioned table.

If you specify any `PARTITION` clauses, then the number of these clauses must be equal to the number of table partitions. You can optionally specify tablespace storage for one or more individual partitions. If you do not specify tablespace storage either here or in the `STORE IN` clause, then the database stores each index partition in the same tablespace as the corresponding table partition.

The `STORE IN` clause lets you specify one or more tablespaces across which Oracle Database will distribute all the index hash partitions. The number of tablespaces need not equal the number of index partitions. If the number of index partitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

For more information on the `USABLE` and `UNUSABLE` clauses, refer to [USABLE | UNUSABLE](#).

***on\_comp\_partitioned\_table***

This clause lets you specify the name and attributes of index partitions on a composite-partitioned table.

The `STORE IN` clause is valid only for range-hash or list-hash composite-partitioned tables. It lets you specify one or more default tablespaces across which Oracle Database will distribute all index hash subpartitions for all partitions. You can override this storage by specifying different default tablespace storage for the subpartitions of an individual partition in the second `STORE IN` clause in the *index\_subpartition\_clause*.

For range-range, range-list, and list-list composite-partitioned tables, you can specify default attributes for the range or list subpartitions in the `PARTITION` clause. You can override this storage by specifying different attributes for the range or list subpartitions of an individual partition in the `SUBPARTITION` clause of the *index\_subpartition\_clause*.

You cannot specify prefix compression for an index partition unless you have specified prefix compression for the index.

For more information on the `USABLE` and `UNUSABLE` clauses, refer to [USABLE | UNUSABLE](#).

***index\_subpartition\_clause***

This clause lets you specify names and tablespace storage for index subpartitions in a composite-partitioned table.

The `STORE IN` clause is valid only for hash subpartitions of a range-hash and list-hash composite-partitioned table. It lets you specify one or more tablespaces across which Oracle Database will distribute all the index hash subpartitions. The `SUBPARTITION` clause is valid for all subpartition types.

If you specify any `SUBPARTITION` clauses, then the number of those clauses must be equal to the number of table subpartitions. If you specify a subpartition name, then it must conform to the rules for naming schema objects and their parts as described in "[Database Object Naming Rules](#)". If you omit *subpartition*, then the database generates a name that is consistent with the corresponding table subpartition. If the name conflicts with an existing index subpartition name, then the database uses the form `SYS_SUBPn`.

The number of tablespaces need not equal the number of index subpartitions. If the number of index subpartitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

If you do not specify tablespace storage for subpartitions either in the *on\_comp\_partitioned\_table* clause or in the *index\_subpartition\_clause*, then Oracle Database uses the tablespace specified for *index*. If you also do not specify tablespace storage for *index*, then the database stores the subpartition in the same tablespace as the corresponding table subpartition.

For more information on the `USABLE` and `UNUSABLE` clauses, refer to CREATE INDEX ... [USABLE | UNUSABLE](#).

#### *domain\_index\_clause*

Use the *domain\_index\_clause* to indicate that *index* is a domain index, which is an instance of an application-specific index of type *indextype*.

Creating a domain index requires a number of preceding operations. You must first create an implementation type for an *indextype*. You must also create a functional implementation and then create an operator that uses the function. Next you create an *indextype*, which associates the implementation type with the operator. Finally, you create the domain index using this clause. Refer to [Extended Examples](#), which contains an example of creating a simple domain index, including all of these operations.

#### *index\_expr*

In the *index\_expr* (in *table\_index\_clause*), specify the table columns or object attributes on which the index is defined. You can define multiple domain indexes on a single column only if the underlying *indextypes* are different and the *indextypes* support a disjoint set of user-defined operators.

#### Restrictions on Domain Indexes

Domain indexes are subject to the following restrictions:

- The *index\_expr* (in *table\_index\_clause*) can specify only a single column, and the column cannot be of data type `REF`, `varray`, `nested table`, `LONG`, or `LONG RAW`.
- You cannot create a bitmap or unique domain index.
- You cannot create a domain index on a temporary table.
- You can create local domain indexes on only range-, list-, hash-, and interval-partitioned tables, with one exception: You cannot create a local domain index on an automatic list-partitioned table.
- Domain indexes can be created only on table columns declared with collation `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`. See *Oracle Database Globalization Support Guide* for more information.

#### *indextype*

For *indextype*, specify the name of the *indextype*. This name should be a valid schema object that has already been created.

If you have installed Oracle Text, then you can use various built-in *indextypes* to create Oracle Text domain indexes. For more information on Oracle Text and the indexes it uses, refer to *Oracle Text Reference*.

 See Also:[CREATE INDEXTYPE](#)***local\_domain\_index\_clause***

Use this clause to specify that the index is a local index on a partitioned table.

- The PARTITIONS clause lets you specify names for the index partitions. The number of partitions you specify must match the number of partitions in the base table. If you omit this clause, then the database creates the partitions with system-generated names of the form `SYS_Pn`.
- The PARAMETERS clause lets you specify the parameter string specific to an individual partition. If you omit this clause, then the parameter string associated with the index is also associated with the partition.

***parallel\_clause***

Use the `parallel_clause` to parallelize creation of the domain index. For a nonpartitioned domain index, Oracle Database passes the explicit or default degree of parallelism to the `ODCIIndexCreate` cartridge routine, which in turn establishes parallelism for the index. For local domain indexes, this clause causes the index partitions to be created in parallel.

 See Also:

[Oracle Database Data Cartridge Developer's Guide](#) for complete information on the Oracle Data Cartridge Interface (ODCI) routines

**PARAMETERS**

In the `PARAMETERS` clause, specify the parameter string that is passed uninterpreted to the appropriate ODCI indextype routine. The maximum length of the parameter string is 1000 characters.

When you specify this clause at the top level of the syntax, the parameters become the default parameters for the index partitions. If you specify this clause as part of the `local_domain_index_clause`, then you override any default parameters with parameters for the individual partition.

After the domain index is created, Oracle Database invokes the appropriate ODCI routine. If the routine does not return successfully, then the domain index is marked FAILED. The only operations supported on a failed domain index are `DROP INDEX` and (for non-local indexes) `REBUILD INDEX`.

 See Also:

[Oracle Database Data Cartridge Developer's Guide](#) for information on the Oracle Data Cartridge Interface (ODCI) routines

### ***XMLIndex\_clause***

The *XMLIndex\_clause* lets you define an `XMLIndex` index, typically on a column containing XML data. An `XMLIndex` index is a type of domain index designed specifically for the domain of XML data.

### ***XMLIndex\_parameters\_clause***

This clause lets you specify information about the path table and about the secondary indexes corresponding to the components of `XMLIndex`. This clause also lets you specify information about the structured component of the index. The maximum length of the parameter string is 1000 characters.

When you specify this clause at the top level of the syntax, the parameters become the parameters of the index and the default parameters for the index partitions. If you specify this clause as part of the *local\_xmlindex\_clause*, then you override any default parameters with parameters for the individual partition.

#### **See Also:**

*Oracle XML DB Developer's Guide* for the syntax and semantics of the *XMLIndex\_parameters\_clause*, as well as detailed information about the use of `XMLIndex`

### ***bitmap\_join\_index\_clause***

Use the *bitmap\_join\_index\_clause* to define a **bitmap join index**. A bitmap join index is defined on a single table. For an index key made up of dimension table columns, it stores the fact table rowids corresponding to that key. In a data warehousing environment, the table on which the index is defined is commonly referred to as a **fact table**, and the tables with which this table is joined are commonly referred to as **dimension tables**. However, a star schema is not a requirement for creating a join index.

#### **ON**

In the `ON` clause, first specify the fact table, and then inside the parentheses specify the columns of the dimension tables on which the index is defined.

#### **FROM**

In the `FROM` clause, specify the joined tables.

#### **WHERE**

In the `WHERE` clause, specify the join condition.

If the underlying fact table is partitioned, then you must also specify one of the *local\_partitioned\_index* clauses (see [local\\_partitioned\\_index](#) ).

#### **Restrictions on Bitmap Join Indexes**

In addition to the restrictions on bitmap indexes in general (see [BITMAP](#)), the following restrictions apply to bitmap join indexes:

- You cannot create a bitmap join index on a temporary table.

- No table may appear twice in the `FROM` clause.
- You cannot create a function-based join index.
- The dimension table columns must be either primary key columns or have unique constraints.
- If a dimension table has a composite primary key, then each column in the primary key must be part of the join.
- You cannot specify the `local_partitioned_index` clause unless the fact table is partitioned.
- A bitmap join index definition can only reference columns with collation `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`. For any of these collations, index keys are collated and the join condition is evaluated using the `BINARY` collation. See *Oracle Database Globalization Support Guide* for more information.

 **Note:**

*Oracle Database Data Warehousing Guide* for information on fact and dimension tables and on using bitmap indexes in a data warehousing environment

## USABLE | UNUSABLE

You can specify the `USABLE` and `UNUSABLE` keywords:

- For an index, in the `CREATE INDEX` statement
- For an index partition, in the `on_range_partitioned_table`, `on_list_partitioned_table`, `on_hash_partitioned_table`, and `on_comp_partitioned_table` clauses
- For an index subpartition, in the `index_subpartition_clause`

For nonpartitioned indexes, specify `UNUSABLE` to create an index in an unusable state. An unusable index must be rebuilt, or dropped and re-created, before it can be used. Specify `USABLE` to create an index in a usable state. `USABLE` is the default.

For partitioned indexes, specify `USABLE` or `UNUSABLE` as follows:

- If you specify `UNUSABLE` for the index, then all index partitions are marked `UNUSABLE`.
- If you specify `USABLE` for the index, then all index partitions are marked `USABLE`.
- If you do not specify `USABLE` or `UNUSABLE` for the index, then all index partitions are marked `USABLE`. The exception is a local partial index. If you specify the `LOCAL` and `INDEXING PARTIAL` clauses, and do not specify `USABLE` or `UNUSABLE`, then each index partition is marked `USABLE` if the indexing property of its corresponding table partition is `ON`, or `UNUSABLE` if the indexing property of its corresponding table partition is `OFF`.

You can override the preceding conditions by specifying `USABLE` or `UNUSABLE` for a specific index partition.

If the underlying table is a composite-partitioned table, then the preceding conditions for index partitions and table partitions apply instead to index subpartitions and table subpartitions.

After you create a partitioned index, you can choose to rebuild specific index partitions or subpartitions to make them `USABLE`. Doing so can be useful if you want to maintain indexes only on some index partitions or subpartitions—for example, if you want to enable index access for new partitions but not for old partitions.

When an index, or some partitions or subpartitions of an index, are created `UNUSABLE`, no segment is allocated for the unusable object. The unusable index or index partition consumes no space in the database.

If an index, or some partitions or subpartitions of the index, are marked `UNUSABLE`, then the index will be considered as an access path by the optimizer only under the following circumstances: the optimizer must know at compile time which partitions are to be accessed, and all of those partitions to be accessed must be marked `USABLE`. Therefore, the query cannot contain any bind variables.

### Restrictions on `USABLE` | `UNUSABLE`

The following restrictions apply when marking an index `USABLE` or `UNUSABLE`:

- You cannot specify this clause for an index on a temporary table.
- Unusable indexes or index partitions will still have a segment under the following conditions:
  - The index (or index partition) is owned by `SYS`, `SYSTEM`, `PUBLIC`, `OUTLN`, or `XDB`
  - The index (or index partition) is stored in dictionary-managed tablespaces
  - The global partitioned or nonpartitioned index on a partitioned table becomes unusable due to a partition maintenance operation

### { `DEFERRED` | `IMMEDIATE` } `INVALIDATION`

This clause lets you control when the database invalidates dependent cursors while creating the index. It has the same semantics here as for the `ALTER INDEX` statement. Refer to [{ `DEFERRED` | `IMMEDIATE` } `INVALIDATION`](#) in the documentation on `ALTER INDEX` for the full semantics of this clause.

### Examples

#### General Index Examples

#### Creating an Index: Example

The following statement shows how the sample index `ord_customer_ix` on the `customer_id` column of the sample table `oe.orders` was created:

```
CREATE INDEX ord_customer_ix
  ON orders (customer_id);
```

#### Compressing an Index: Example

To create the `ord_customer_ix_demo` index with the `COMPRESS` clause, you might issue the following statement:

```
CREATE INDEX ord_customer_ix_demo
  ON orders (customer_id, sales_rep_id)
  COMPRESS 1;
```

The index will compress repeated occurrences of `customer_id` column values.

### Creating an Index in NOLOGGING Mode: Example

If the sample table `orders` had been created using a fast parallel load (so all rows were already sorted), then you could issue the following statement to quickly create an index.

```
/* Unless you first sort the table oe.orders, this example fails
   because you cannot specify NOSORT unless the base table is
   already sorted.
*/
CREATE INDEX ord_customer_ix_demo
  ON orders (order_mode)
  NOSORT
  NOLOGGING;
```

### Creating a Cluster Index: Example

To create an index for the `personnel` cluster, which was created in "[Creating a Cluster: Example](#)", issue the following statement:

```
CREATE INDEX idx_personnel ON CLUSTER personnel;
```

No index columns are specified, because cluster indexes are automatically built on all the columns of the cluster key. For cluster indexes, all rows are indexed.

### Creating an Index on an XMLType Table: Example

The following example creates an index on the `area` element of the `xwarehouses` table (created in "[XMLType Table Examples](#)"):

```
CREATE INDEX area_index ON xwarehouses e
  (EXTRACTVALUE(VALUE(e), '/Warehouse/Area'));
```

Such an index would greatly improve the performance of queries that select from the table based on, for example, the square footage of a warehouse, as shown in this statement:

```
SELECT e.getClobVal() AS warehouse
  FROM xwarehouses e
 WHERE EXISTSNODE(VALUE(e), '/Warehouse[Area>50000]') = 1;
```

#### See Also:

[EXISTSNODE](#) and [VALUE](#)

## Function-Based Index Examples

The following examples show how to create and use function-based indexes.

### Creating a Function-Based Index: Example

The following statement creates a function-based index on the `employees` table based on an uppercase evaluation of the `last_name` column:

```
CREATE INDEX upper_ix ON employees (UPPER(last_name));
```

See the "[Prerequisites](#)" for the privileges and parameter settings required when creating function-based indexes.

To increase the likelihood that Oracle Database will use the index rather than performing a full table scan, be sure that the value returned by the function is not null in subsequent queries. For example, this statement will use the index, unless some other condition exists that prevents the optimizer from doing so:

```
SELECT first_name, last_name
  FROM employees WHERE UPPER(last_name) IS NOT NULL
 ORDER BY UPPER(last_name);
```

Without the `WHERE` clause, Oracle Database may perform a full table scan.

In the next statements showing index creation and subsequent query, Oracle Database will use index `income_ix` even though the columns are in reverse order in the query:

```
CREATE INDEX income_ix
  ON employees(salary + (salary*commission_pct));

SELECT first_name||' '||last_name "Name"
  FROM employees
 WHERE (salary*commission_pct) + salary > 15000
 ORDER BY employee_id;
```

### Creating a Function-Based Index on a LOB Column: Example

The following statement uses the `text_length` function to create a function-based index on a LOB column in the sample `pm` schema. See *Oracle Database PL/SQL Language Reference* for the example that creates this function. The example selects rows from the sample table `print_media` where that `CLOB` column has fewer than 1000 characters.

```
CREATE INDEX src_idx ON print_media(text_length(ad_sourcetext));

SELECT product_id FROM print_media
 WHERE text_length(ad_sourcetext) < 1000
 ORDER BY product_id;

PRODUCT_ID
-----
2056
2268
3060
3106
```

### Creating a Function-based Index on a Type Method: Example

This example entails an object type `rectangle` containing two number attributes: `length` and `width`. The `area()` method computes the area of the rectangle.

```
CREATE TYPE rectangle AS OBJECT
( length  NUMBER,
  width   NUMBER,
  MEMBER FUNCTION area RETURN NUMBER DETERMINISTIC
);

CREATE OR REPLACE TYPE BODY rectangle AS
  MEMBER FUNCTION area RETURN NUMBER IS
  BEGIN
    RETURN (length*width);
  END;
END;
```

Now, if you create a table `rect_tab` of type `rectangle`, you can create a function-based index on the `area()` method as follows:

```
CREATE TABLE rect_tab OF rectangle;
CREATE INDEX area_idx ON rect_tab x (x.area());
```

You can use this index efficiently to evaluate a query of the form:

```
SELECT * FROM rect_tab x WHERE x.area() > 100;
```

### Using a Function-based Index to Define Conditional Uniqueness: Example

The following statement creates a unique function-based index on the `oe.orders` table that prevents a customer from taking advantage of promotion ID 2 ("blowout sale") more than once:

```
CREATE UNIQUE INDEX promo_ix ON orders
  (CASE WHEN promotion_id =2 THEN customer_id ELSE NULL END,
   CASE WHEN promotion_id = 2 THEN promotion_id ELSE NULL END);

INSERT INTO orders (order_id, order_date, customer_id, order_total, promotion_id)
  VALUES (2459, systimestamp, 106, 251, 2);
1 row created.

INSERT INTO orders (order_id, order_date, customer_id, order_total, promotion_id)
  VALUES (2460, systimestamp+1, 106, 110, 2);
insert into orders (order_id, order_date, customer_id, order_total, promotion_id)
*
ERROR at line 1:
ORA-00001: unique constraint (OE.PROMO_IX) violated
```

The objective is to remove from the index any rows where the `promotion_id` is not equal to 2. Oracle Database does not store in the index any rows where all the keys are `NULL`. Therefore, in this example, both `customer_id` and `promotion_id` are mapped to `NULL` unless `promotion_id` is equal to 2. The result is that the index constraint is violated only if `promotion_id` is equal to 2 for two rows with the same `customer_id` value.

## Partitioned Index Examples

### Creating a Range-Partitioned Global Index: Example

The following statement creates a global prefixed index `cost_ix` on the sample table `sh.sales` with three partitions that divide the range of costs into three groups:

```
CREATE INDEX cost_ix ON sales (amount_sold)
  GLOBAL PARTITION BY RANGE (amount_sold)
    (PARTITION p1 VALUES LESS THAN (1000),
     PARTITION p2 VALUES LESS THAN (2500),
     PARTITION p3 VALUES LESS THAN (MAXVALUE));
```

### Creating a Hash-Partitioned Global Index: Example

The following statement creates a hash-partitioned global index `cust_last_name_ix` on the sample table `sh.customers` with four partitions:

```
CREATE INDEX cust_last_name_ix ON customers (cust_last_name)
  GLOBAL PARTITION BY HASH (cust_last_name)
  PARTITIONS 4;
```

### Creating an Index on a Hash-Partitioned Table: Example

The following statement creates a local index on the `category_id` column of the `hash_products` partitioned table (which was created in "[Hash Partitioning Example](#)"). The `STORE IN` clause immediately following `LOCAL` indicates that `hash_products` is hash partitioned. Oracle Database will distribute the hash partitions between the `tbs1` and `tbs2` tablespaces:

```
CREATE INDEX prod_idx ON hash_products(category_id) LOCAL
    STORE IN (tbs_01, tbs_02);
```

The creator of the index must have quota on the tablespaces specified. See [CREATE TABLESPACE](#) for examples that create tablespaces `tbs_01` and `tbs_02`.

### Creating an Index on a Composite-Partitioned Table: Example

The following statement creates a local index on the `composite_sales` table, which was created in "[Composite-Partitioned Table Examples](#)". The `STORAGE` clause specifies default storage attributes for the index. However, this default is overridden for the five subpartitions of partitions `q3_2000` and `q4_2000`, because separate `TABLESPACE` storage is specified.

The creator of the index must have quota on the tablespaces specified. See [CREATE TABLESPACE](#) for examples that create tablespaces `tbs_02` and `tbs_03`.

```
CREATE INDEX sales_ix ON composite_sales(time_id, prod_id)
    STORAGE (INITIAL 1M)
    LOCAL
        (PARTITION q1_1998,
         PARTITION q2_1998,
         PARTITION q3_1998,
         PARTITION q4_1998,
         PARTITION q1_1999,
         PARTITION q2_1999,
         PARTITION q3_1999,
         PARTITION q4_1999,
         PARTITION q1_2000,
         PARTITION q2_2000
             (SUBPARTITION pq2001, SUBPARTITION pq2002,
              SUBPARTITION pq2003, SUBPARTITION pq2004,
              SUBPARTITION pq2005, SUBPARTITION pq2006,
              SUBPARTITION pq2007, SUBPARTITION pq2008),
         PARTITION q3_2000
             (SUBPARTITION c1 TABLESPACE tbs_02,
              SUBPARTITION c2 TABLESPACE tbs_02,
              SUBPARTITION c3 TABLESPACE tbs_02,
              SUBPARTITION c4 TABLESPACE tbs_02,
              SUBPARTITION c5 TABLESPACE tbs_02),
         PARTITION q4_2000
             (SUBPARTITION pq4001 TABLESPACE tbs_03,
              SUBPARTITION pq4002 TABLESPACE tbs_03,
              SUBPARTITION pq4003 TABLESPACE tbs_03,
              SUBPARTITION pq4004 TABLESPACE tbs_03)
    );
;
```

### Bitmap Index Examples

The following creates a bitmap index on the table `oe.hash_products`, which was created in "[Hash Partitioning Example](#)":

```
CREATE BITMAP INDEX product_bm_ix
    ON hash_products(list_price)
```

```

LOCAL(PARTITION ix_p1 TABLESPACE tbs_01,
      PARTITION ix_p2,
      PARTITION ix_p3 TABLESPACE tbs_02,
      PARTITION ix_p4 TABLESPACE tbs_03)
TABLESPACE tbs_04;

```

Because `hash_products` is a partitioned table, the bitmap join index must be locally partitioned. In this example, the user must have quota on tablespaces specified. See [CREATE TABLESPACE](#) for examples that create tablespaces `tbs_01`, `tbs_02`, `tbs_03`, and `tbs_04`.

The next series of statements shows how one might create a bitmap join index on a fact table using a join with a dimension table.

```

CREATE TABLE hash_products
  ( product_id          NUMBER(6)
  , product_name        VARCHAR2(50)
  , product_description VARCHAR2(2000)
  , category_id         NUMBER(2)
  , weight_class        NUMBER(1)
  , warranty_period     INTERVAL YEAR TO MONTH
  , supplier_id         NUMBER(6)
  , product_status      VARCHAR2(20)
  , list_price          NUMBER(8,2)
  , min_price           NUMBER(8,2)
  , catalog_url         VARCHAR2(50)
  , CONSTRAINT pk_product_id PRIMARY KEY (product_id)
  , CONSTRAINT product_status_lov_demo
    CHECK (product_status in ('orderable'
                             , 'planned'
                             , 'under development'
                             , 'obsolete'))
  )
PARTITION BY HASH (product_id)
PARTITIONS 5
STORE IN (example);

CREATE TABLE sales_quota
  ( product_id          NUMBER(6)
  , customer_name       VARCHAR2(50)
  , order_qty           NUMBER(6)
  ,CONSTRAINT u_product_id UNIQUE(product_id)
  );

CREATE BITMAP INDEX product_bm_ix
  ON hash_products(list_price)
  FROM hash_products h, sales_quota s
  WHERE h.product_id = s.product_id
  LOCAL(PARTITION ix_p1 TABLESPACE example,
        PARTITION ix_p2,
        PARTITION ix_p3 TABLESPACE example,
        PARTITION ix_p4,
        PARTITION ix_p5 TABLESPACE example)
  TABLESPACE example;

```

### Indexes on Nested Tables: Example

The sample table `pm.print_media` contains a nested table column `ad_textdocs_ntab`, which is stored in storage table `textdocs_nestedtab`. The following example creates a unique index on storage table `textdocs_nestedtab`:

```
CREATE UNIQUE INDEX nested_tab_ix
    ON textdocs_nestedtab(NESTED_TABLE_ID, document_typ);
```

Including pseudocolumn NESTED\_TABLE\_ID ensures distinct rows in nested table column ad\_textdocs\_ntab.

### Indexing on Substitutable Columns: Examples

You can build an index on attributes of the declared type of a substitutable column. In addition, you can reference the subtype attributes by using the appropriate TREAT function. The following example uses the table books, which is created in "Substitutable Table and Column Examples". The statement creates an index on the salary attribute of all employee authors in the books table:

```
CREATE INDEX salary_i
    ON books (TREAT(author AS employee_t).salary);
```

The target type in the argument of the TREAT function must be the type that added the attribute being referenced. In the example, the target of TREAT is employee\_t, which is the type that added the salary attribute.

If this condition is not satisfied, then Oracle Database interprets the TREAT function as any functional expression and creates the index as a function-based index. For example, the following statement creates a function-based index on the salary attribute of part-time employees, assigning nulls to instances of all other types in the type hierarchy.

```
CREATE INDEX salary_func_i ON persons p
    (TREAT(VALUE(p) AS part_time_emp_t).salary);
```

You can also build an index on the type-discriminant column underlying a substitutable column by using the SYS\_TYPEID function.

#### Note:

Oracle Database uses the type-discriminant column to evaluate queries that involve the IS OF type condition. The cardinality of the typeid column is normally low, so Oracle recommends that you build a bitmap index in this situation.

The following statement creates a bitmap index on the typeid of the author column of the books table:

```
CREATE BITMAP INDEX typeid_i ON books (SYS_TYPEID(author));
```

#### See Also:

- Oracle Database PL/SQL Language Reference to see the creation of the type hierarchy underlying the books table
- the functions TREAT and SYS\_TYPEID and the condition "IS OF type Condition "

# CREATE INDEXTYPE

## Purpose

Use the `CREATE INDEXTYPE` statement to create an **indextype**, which is an object that specifies the routines that manage a domain (application-specific) index. Indextypes reside in the same namespace as tables, views, and other schema objects. This statement binds the indextype name to an implementation type, which in turn specifies and refers to user-defined index functions and procedures that implement the indextype.

 **See Also:**

*Oracle Database Data Cartridge Developer's Guide* for more information on implementing indextypes

## Prerequisites

To create an indextype in your own schema, you must have the `CREATE INDEXTYPE` system privilege. To create an indextype in another schema, you must have the `CREATE ANY INDEXTYPE` system privilege. In either case, you must have the `EXECUTE` object privilege on the implementation type and the supported operators.

An indextype supports one or more operators, so before creating an indextype, you must first design the operator or operators to be supported and provide functional implementation for those operators.

 **See Also:**

[CREATE OPERATOR](#)

## Syntax

*create\_indextype ::=*

*using\_type\_clause ::=*

*array\_DML\_clause ::=*

*storage\_table\_clause ::=*

## Semantics

### OR REPLACE

Specify `OR REPLACE` to re-create the indextype if it already exists. You can use this clause to change the definition of an existing indextype without dropping, re-creating, and regranting object privileges previously granted on it.

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the indextype does not exist, a new indextype is created at the end of the statement.
- If the indextype exists, this is the indextype you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error:

ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

### *schema*

Specify the name of the schema in which the indextype resides. If you omit `schema`, then Oracle Database creates the indextype in your own schema.

### *indextype*

Specify the name of the indextype to be created. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)".

### SHARING

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- `METADATA` - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- `NONE` - The object is not shared and can only be accessed in the application root.

### FOR Clause

Use the `FOR` clause to specify the list of operators supported by the indextype.

- For `schema`, specify the schema containing the operator. If you omit `schema`, then Oracle assumes the operator is in your own schema.
- For `operator`, specify the name of the operator supported by the indextype.  
All the operators listed in this clause must be valid operators.
- For `parameter_type`, list the types of parameters to the operator.

### ***using\_type\_clause***

The `USING` clause lets you specify the type that provides the implementation for the new indextype.

For `implementation_type`, specify the name of the type that implements the appropriate Oracle Data Cartridge Interface (ODCI).

- You must specify a valid type that implements the routines in the ODCI.
- The implementation type must reside in the same schema as the indextype.

 **See Also:**

*Oracle Database Data Cartridge Developer's Guide* for additional information on this interface

### **WITH LOCAL PARTITION**

Use this clause to indicate that the indextype can be used to create local domain indexes on range-, list-, hash-, and interval-partitioned tables. You use this clause in combination with the `storage_table_clause` in several ways (see [storage\\_table\\_clause](#)).

- The recommended method is to specify `WITH LOCAL PARTITION WITH SYSTEM MANAGED STORAGE TABLES`. This combination uses *system-managed* storage tables, which are the preferred storage management, and lets you create local domain indexes on range-, list-, hash-, and interval-partitioned tables. In this case the `RANGE` keyword is optional and ignored, because it is no longer needed if you specify `WITH LOCAL PARTITION WITH SYSTEM MANAGED STORAGE TABLES`.
- You can specify `WITH LOCAL RANGE PARTITION` (including the `RANGE` keyword) and omit the `storage_table` clause. Local domain indexes on range-partitioned tables are supported with *user-managed* storage tables for backward compatibility. Oracle does not recommend this combination because it uses the less efficient user-managed storage tables.

If you omit this clause entirely, then you cannot subsequently use this indextype to create a local domain index on a range, list-, hash-, or interval-partitioned table.

### ***storage\_table\_clause***

Use this clause to specify how storage tables and partition maintenance operations for indexes built on this indextype are managed:

- Specify `WITH SYSTEM MANAGED STORAGE TABLES` to indicate that the storage of statistics data is to be managed by the system. The type you specify in `statistics_type` should be storing the statistics related information in tables that are maintained by the system. Also, the indextype you specify must already have been created or altered to support the `WITH SYSTEM MANAGED STORAGE TABLES` clause.
- Specify `WITH USER MANAGED STORAGE TABLES` to indicate that the tables that store the user-defined statistics will be managed by the user. This is the default behavior.

 **See Also:**

*Oracle Database Data Cartridge Developer's Guide* for more information about storage tables for domain indexes

**array\_DML\_clause**

Use this clause to let the indextype support the array interface for the ODCIIndexInsert method.

**type and varray\_type**

If the data type of the column to be indexed is a user-defined object type, then you must specify this clause to identify the varray *varray\_type* that Oracle should use to hold column values of *type*. If the indextype supports a list of types, then you can specify a corresponding list of varray types. If you omit *schema* for either *type* or *varray\_type*, then Oracle assumes the type is in your own schema.

If the data type of the column to be indexed is a built-in system type, then any varray type specified for the indextype takes precedence over the ODCI types defined by the system.

 **See Also:**

*Oracle Database Data Cartridge Developer's Guide* for more information on the ODCI array interface

**Examples****Creating an Indextype: Example**

The following statement creates an indextype named `position_indextype` and specifies the `position_between` operator that is supported by the indextype and the `position_im` type that implements the index interface. Refer to "[Using Extensible Indexing](#)" for an extensible indexing scenario that uses this indextype:

```
CREATE INDEXTYPE position_indextype
  FOR position_between(NUMBER, NUMBER, NUMBER)
  USING position_im;
```

# CREATE INMEMORY JOIN GROUP

**Purpose**

Use the CREATE INMEMORY JOIN GROUP statement to create a join group, which is an object that specifies frequently joined columns from the same table or different tables. Such columns typically contain values of compatible data types that fall in similar ranges. When you create a join group, Oracle Database stores special metadata for the columns in the global dictionary, which enables the database to optimize join queries for the columns. In order to achieve this optimization, the table columns must be populated in the In-Memory Column Store (IM column store).

Creating a join group for tables causes the current In-Memory contents of these tables to be invalidated. Subsequent repopulation causes the In-Memory Compression Units (IMCUs) of the tables to be re-encoded with the global dictionary. Thus, Oracle recommends that you first create the join group, and then populate the tables.

### See Also:

- [ALTER INMEMORY JOIN GROUP](#) and [DROP INMEMORY JOIN GROUP](#)
- [Oracle Database In-Memory Guide](#) for more information on join groups

### Prerequisites

To create a join group in another user's schema, or to include in the join group a column in a table in another user's schema, you must have the `CREATE ANY TABLE` system privilege.

### Syntax

`create_inmemory_join_group ::=`

### Semantics

#### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the object does not exist, a new object is created at the end of the statement.
- If the object exists, this is the object you have at the end of the statement. A new one is not created because the older object is detected.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

#### `schema`

Specify the schema to contain the join group. If you omit `schema`, then the database creates the join group in your own schema.

#### `join_group`

Specify the name of the join group to be created. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)".

***schema***

Specify the schema of the table that contains a column to be included in the join group. If you omit *schema*, then Oracle Database assumes the table is in your own schema.

***table***

Specify the name of the table that contains a column to be included in the join group.

***column***

Specify the name of a column to be included in the join group. A join group can contain columns in the same table or different tables.

**Restrictions on Join Groups**

The following restrictions apply to join groups:

- A join group must contain at least 1 column.
- A join group can contain at most 255 columns.
- A table column can be a member of at most one join group.
- Oracle Active Data Guard does not support join groups.

**Examples**

The following statement creates a join group named `prod_id1` in the `oe` schema. Both tables involved in this join group reside in the `oe` schema.

```
CREATE INMEMORY JOIN GROUP prod_id1
  (inventories(product_id), order_items(product_id));
```

The following statement creates a join group named `prod_id2` in the `oe` schema. The table `inventories` resides in the `oe` schema and the table `online_media` resides in the `pm` schema.

```
CREATE INMEMORY JOIN GROUP prod_id2
  (inventories(product_id), pm.online_media(product_id));
```

# CREATE JAVA

**Purpose**

Use the `CREATE JAVA` statement to create a schema object containing a Java source, class, or resource.

 **See Also:**

- *Oracle Database Java Developer's Guide* for Java concepts and information about Java stored procedures
- *Oracle Database JDBC Developer's Guide* for information on JDBC

## Prerequisites

To create or replace a schema object containing a Java source, class, or resource in your own schema, you must have `CREATE PROCEDURE` system privilege. To create or replace such a schema object in another user's schema, you must have `CREATE ANY PROCEDURE` system privilege.

## Syntax

`create_java::=`

`invoker_rights_clause::=`

## Semantics

### OR REPLACE

Specify `OR REPLACE` to re-create the schema object containing the Java class, source, or resource if it already exists. Use this clause to change the definition of an existing

object without dropping, re-creating, and regranting object privileges previously granted.

If you redefine a Java schema object and specify `RESOLVE` or `COMPILE`, then Oracle Database recompiles or resolves the object. Whether or not the resolution or compilation is successful, the database invalidates classes that reference the Java schema object.

Users who had previously been granted privileges on a redefined function can still access the function without being regranted the privileges.

#### See Also:

[ALTER JAVA](#) for additional information

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the object does not exist, a new object is created at the end of the statement.
- If the object exists, this is the object you have at the end of the statement. A new one is not created because the older one is detected.

You can have `one of` `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error:  
`ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

### RESOLVE | COMPILE

`RESOLVE` and `COMPILE` are synonymous keywords. They specify that Oracle Database should attempt to resolve the Java schema object that is created if this statement succeeds.

- When applied to a class, resolution of referenced names to other class schema objects occurs.
- When applied to a source, source compilation occurs.

### Restriction on RESOLVE and COMPILE

You cannot specify these keywords for a Java resource.

### NOFORCE

Specify `NOFORCE` to roll back the results of this `CREATE` command if you have specified either `RESOLVE` or `COMPILE` and the resolution or compilation fails. If you do not specify this option, then Oracle Database takes no action if the resolution or compilation fails, and the created schema object remains.

### JAVA SOURCE Clause

Specify `JAVA SOURCE` to load a Java source file.

### JAVA CLASS Clause

Specify `JAVA CLASS` to load a Java class file.

## JAVA RESOURCE Clause

Specify `JAVA RESOURCE` to load a Java resource file.

### NAMED Clause

The `NAMED` clause is required for a Java source or resource. The *primary\_name* must be enclosed in double quotation marks and its length must not exceed 4000 bytes in the database character set.

- For a Java source, this clause specifies the name of the schema object in which the source code is held. A successful `CREATE JAVA SOURCE` statement will also create additional schema objects to hold each of the Java classes defined by the source.
- For a Java resource, this clause specifies the name of the schema object to hold the Java resource.

Use double quotation marks to preserve a lower- or mixed-case *primary\_name*.

If you do not specify *schema*, then Oracle Database creates the object in your own schema.

### Restrictions on NAMED Java Classes

The `NAMED` clause is subject to the following restrictions:

- You cannot specify `NAMED` for a Java class.
- The *primary\_name* cannot contain a database link.

### SCHEMA Clause

The `SCHEMA` clause applies only to a Java class. This optional clause specifies the schema in which the object containing the Java file will reside. If you do not specify this clause, then Oracle Database creates the object in your own schema.

### SHARING

This clause applies only when creating a Java schema object in an application root. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root. To determine how the Java schema object is shared, specify one of the following sharing attributes:

- **METADATA** - A metadata link shares the Java schema object's metadata, but its data is unique to each container. This type of Java schema object is referred to as a **metadata-linked application common object**.
- **NONE** - The Java schema object is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the Java schema object. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is `METADATA`.

You cannot change the sharing attribute of a Java schema object after it is created.

 See Also:

- *Oracle Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
- *Oracle Database Administrator's Guide* for complete information on creating application common objects

***invoker\_rights\_clause***

Use the `invoker_rights_clause` to indicate whether the methods of the class execute with the privileges and in the schema of the user who owns the class or with the privileges and in the schema of `CURRENT_USER`.

This clause also determines how Oracle Database resolves external names in queries, DML operations, and dynamic SQL statements in the member functions and procedures of the type.

**AUTHID CURRENT\_USER**

`CURRENT_USER` indicates that the methods of the class execute with the privileges of `CURRENT_USER`. This clause is the default and creates an **invoker-rights class**.

This clause also specifies that external names in queries, DML operations, and dynamic SQL statements resolve in the schema of `CURRENT_USER`. External names in all other statements resolve in the schema in which the methods reside.

**AUTHID DEFINER**

`DEFINER` indicates that the methods of the class execute with the privileges of the owner of the schema in which the class resides, and that external names resolve in the schema where the class resides. This clause creates a **definer-rights class**.

 See Also:

- *Oracle Database Java Developer's Guide*
- *Oracle Database PL/SQL Language Reference* for information on how `CURRENT_USER` is determined

**RESOLVER Clause**

The `RESOLVER` clause lets you specify a mapping of the fully qualified Java name to a Java schema object, where:

- `match_string` is either a fully qualified Java name, a wildcard that can match such a Java name, or a wildcard that can match any name.
- `schema_name` designates a schema to be searched for the corresponding Java schema object.

- A dash (-) as an alternative to *schema\_name* indicates that if *match\_string* matches a valid Java name, Oracle Database can leave the name unresolved. The resolution succeeds, but the name cannot be used at run time by the class.

This mapping is stored with the definition of the schema objects created in this command for use in later resolutions (either implicit or in explicit ALTER JAVA ... RESOLVE statements).

### USING Clause

The USING clause determines a sequence of character data (CLOB or BFILE) or binary data (BLOB or BFILE) for the Java class or resource. Oracle Database uses the sequence of characters to define one file for a Java class or resource, or one source file and one or more derived classes for a Java source.

### BFILE Clause

Specify the directory and filename of a previously created file on the operating system (*directory\_object\_name*) and server file (*server\_file\_name*) containing the sequence. BFILE is usually interpreted as a character sequence by CREATE JAVA SOURCE and as a binary sequence by CREATE JAVA CLASS or CREATE JAVA RESOURCE.

### CLOB | BLOB | BFILE subquery

Specify a subquery that selects a single row and column of the type specified (CLOB, BLOB, or BFILE). The value of the column makes up the sequence of characters.

#### Note:

In earlier releases, the USING clause implicitly supplied the keyword SELECT. This is no longer the case. However, the subquery without the keyword SELECT is still supported for backward compatibility.

### key\_for\_BLOB

The *key\_for\_BLOB* clause supplies the following implicit query:

```
SELECT LOB FROM CREATE$JAVA$LOB$TABLE  
WHERE NAME = 'key_for_BLOB';
```

### Restriction on the *key\_for\_BLOB* Clause

For you to use this case, the table CREATE\$JAVA\$LOB\$TABLE must exist in the current schema and must have a column LOB of type BLOB and a column NAME of type VARCHAR2.

### AS *source\_char*

Specify a sequence of characters for a Java source.

### Examples

#### Creating a Java Class Object: Example

The following statement creates a schema object containing a Java class using the name found in a Java binary file:

```
CREATE JAVA CLASS USING BFILE (java_dir, 'Agent.class')
/
```

This example assumes the directory object `java_dir`, which points to the operating system directory containing the Java class `Agent.class`, already exists. In this example, the name of the class determines the name of the Java class schema object.

### **Creating a Java Source Object: Example**

The following statement creates a Java source schema object:

```
CREATE JAVA SOURCE NAMED "Welcome" AS
  public class Welcome {
    public static String welcome() {
      return "Welcome World"; } }
/

```

### **Creating a Java Resource Object: Example**

The following statement creates a Java resource schema object named `appText` from a bfile:

```
CREATE JAVA RESOURCE NAMED "appText"
  USING BFILE (java_dir, 'textBundle.dat')
/

```

# SQL Statements: CREATE JSON RELATIONAL DUALITY VIEW to CREATE SCHEMA

This chapter contains the following SQL statements:

- [CREATE JSON RELATIONAL DUALITY VIEW](#)
- [CREATE LIBRARY](#)
- [CREATE LOCKDOWN PROFILE](#)
- [CREATE MATERIALIZED VIEW](#)
- [CREATE MATERIALIZED VIEW LOG](#)
- [CREATE MATERIALIZED ZONEMAP](#)
- [CREATE OPERATOR](#)
- [CREATE OUTLINE](#)
- [CREATE PACKAGE](#)
- [CREATE PACKAGE BODY](#)
- [CREATE PFILE](#)
- [CREATE PLUGGABLE DATABASE](#)
- [CREATE PROCEDURE](#)
- [CREATE PROFILE](#)
- [CREATE RESTORE POINT](#)
- [CREATE ROLE](#)
- [CREATE ROLLBACK SEGMENT](#)
- [CREATE SCHEMA](#)

## CREATE JSON RELATIONAL DUALITY VIEW

### Purpose

JSON-relational duality views expose data in relational tables as JSON documents. The documents are materialized on demand, not stored as such. Duality views give your data a conceptual and an operational duality as it is organized both relationally and hierarchically. You can base different duality views on data stored in one or more of the same tables, providing different JSON hierarchies over the same, shared data. This means that applications can access (create, query, modify) the same data as a collection of JSON documents or as a set of related tables and columns, and both approaches can be employed at the same time.

You define a duality view against a set of tables related by primary key (PK), foreign key (FK) or unique key constraints (UK). The following rules apply:

- The constraints must be declared in the database but need not be enforced (can be `RELY DISABLE` constraints).
- The relationships type can be 1-to-1, 1-to-N and N-to-M (using a mapping table with two FKs). The N-to-M relationship can be thought of as the combination of 1-to-N and 1-to-1 relationship
- Columns of two or more tables with 1-to-1 or N-to-1 relationships can be merged into the same JSON object via `UNNEST`. Otherwise a nested JSON object is created.
- Tables with a 1-to-N relationship create a nested JSON array.
- A duality view has only one column of type `JSON`.
- Each row in the duality view is one JSON object, which is typically a hierarchy of nested objects and arrays.
- Each application object is built from values originating from one or multiple rows from the underlying tables of that view. Typically, each table contributes to one (nested) JSON object.

 **See Also:**

*JSON-Relational Duality Developer's Guide*

## Syntax

`create_json_relational_duality_view ::=`

`object_gen_clause ::=`

**key\_value\_clause ::=**

*letter ::=*

*upper\_letter ::=*

*lower\_letter ::=*

*digit*::=

*selection\_set*::=

*selection\_list*::=

### ***selection::=***

### ***field*::=**

(*directives*::=, *selection\_set*::=)

*alias*::=

*query\_field\_name*::=

*query\_scalar\_field\_name ::=*

*query\_object\_field\_name ::=*

*fragment\_spread ::=*

*fragment\_name*

*quoted\_name ::=*

*lower\_case\_name ::=*

*name\_continue\_lower ::=*

***field\_name ::=***

***scalar\_field\_name ::=***

***object\_field\_name ::=***

***object\_field\_name\_lower ::=***

***schema\_name\_lower ::=***

***simple\_object\_type\_name\_lower ::=***

### Semantics

The JSON relational duality view (DV) has only one column of data type `JSON`. The column contains the JSON object which is a representation of a application object. The column name is always `DATA`.

The duality view is read-only by default. Read-only means that the following annotations are in effect: `NOINSERT`, `NODELETE`, `NOUPDATE`.

## OR REPLACE

Specify `OR REPLACE` to re-create the view if it already exists. You can use this clause to change the definition of an existing view without dropping, re-creating, and regranting object privileges previously granted on it.

## IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the view does not exist, a new view is created at the end of the statement.
- If the view exists, this is the view you have at the end of the statement. A new one is not created because the older one is detected.

You can have only one of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both in the same statement results in the following error:

ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement

### ***table\_tag\_clause***

You can mark the view as updatable using the following keyword inside a `WITH` clause:

- `WITH INSERT`
- `WITH UPDATE`
- `WITH DELETE`

You can combine keywords together by separating them with a comma, for example: `WITH INSERT, UPDATE`

### ***column\_tags\_clause***

You can mark individual columns with `WITH UPDATE` or `WITH NOUPDATE`. This supercedes table-level annotation.

## Column Properties for Updatability

If the `FROM` clause is marked with such keywords, then this sets the default for all columns of the table in the `FROM` clause. You can change the default setting on an individual column. If a the `FROM` clause is specified as `WITH (INSERT, UPDATE, DELETE)` and a column overrides this default with `NOUPDATE`, then updates are not allowed.

## Column Properties for ETAGs

Individual columns as well as a `FROM` clause can be specified to take part in the `CHECK ETAG` calculation or not. An `ETAG` is a hash value for all the columns' values in one JSON object and is used to detect changes. A column without `ETAG` can be changed without this change impacting other operations. By default all columns participate in `ETAG` calculation. Using `NOCHECK ETAG` a column can be excluded from `ETAG` calculation.

### ***graphql\_query\_for\_DV***

`graphql_query_for_DV` is a special kind of shorthand query operation definition in GraphQL.

- The `root_query_field` is the single top-level selection field of this shorthand query.

For brevity, `graphql_query_for_dv` omits the pair of curly brackets of the top-level `selection_set` of a general shorthand query operation.

- `selection_set` syntax augments the selection set defined in the GraphQL specification with the option of optional square brackets around the selection list.
- `selection in selection_list` can be only `field` or `fragment_spread`.
- `field directives`: conform to the GraphQL specification. Only supported custom directives are allowed. `@skip` and `@include` are NOT supported.
- `argument` conforms to the GraphQL specification.
- `root_query_field_name` corresponds to the root table.
- `name` has the same syntax as the GraphQL specification.
- `quoted_name`: The field names in a GraphQL query for DV allow quoted and unquoted names. As a convention, un-quoted field names are in lower case only. `any_char` is any character allowed in a quoted identifier in SQL .
- `scalar_field_name` corresponds to a column name of a table.
- `object_field_name` corresponds to a related table name. In addition you can use quoted names, and fully qualified table names with dot-concatenation.

## Examples

### See Also:

- *Introduction To Car-Racing Duality Views Example* of the JSON-Relational Duality Developer's Guide.

## Example 1: Create a Duality View of Orders

The following example is a view of an orders view object `ORDERS_OV` with the following information:

- Order information such as order status from the `Orders` table
- A `CustomerInfo` singleton descendant consisting of customer details from the `Customer` table
- An `OrderItems` array descendant consisting of a list of order items from the `OrderItems` table.
- Each order item, in turn, consists of `ItemInfo` and `ShipmentInfo` singletons from the `Products` and `Shipment` tables respectively.

```
CREATE OR REPLACE JSON RELATIONAL DUALITY VIEW ORDERS_OV AS
SELECT JSON { 'OrderId' : ord.order_id,
               'OrderTime' : ord.order_datetime,
               'OrderStatus' : ord.order_status,
               'CustomerInfo' :
                 (SELECT JSON{'CustomerId' : cust.customer_id,
                               'CustomerName' : cust.full_name,
                               'CustomerEmail' :
                                 cust.email_address })}
```

```

        FROM CUSTOMERS cust
          WHERE cust.customer_id = ord.customer_id),
'OrderItems' : (SELECT JSON_ARRAYAGG(
                JSON { 'OrderItemId' : oi.line_item_id,
                       'Quantity'   :
                           oi.quantity,
                           'ProductInfo' : <subquery from product>
                           'ShipmentInfo' : <subquery from
shipments>)

            })
          FROM ORDER_ITEMS oi
          WHERE ord.order_id = oi.order_id)
}
FROM ORDERS ord;

```

### Example 2: Create an Updatable View

To make the view updatable, one has to add `INSERT` or `UPDATE` or `DELETE` or any combination of these to either the `FROM` clause or individual column. The following allows to update the order, only read the customer and insert and update (not delete) order items.

```

CREATE OR REPLACE JSON RELATIONAL DUALITY VIEW ORDERS_OV AS
SELECT JSON { 'OrderId'      : ord.order_id,
              'OrderTime'    : ord.order_datetime,
              'OrderStatus'  : ord.order_status,
              'CustomerInfo' :
                  (SELECT JSON{ 'CustomerId'    : cust.customer_id,
                                'CustomerName' : cust.full_name,
                                'CustomerEmail': cust.email_address WITH
NOCHECK}
                   FROM CUSTOMERS c WITH CHECK
                     WHERE cust.customer_id = ord.customer_id),
              'OrderItems'   : (SELECT JSON_ARRAYAGG(
                  JSON { 'OrderItemId' : oi.line_item_id,
                         'Quantity'   : oi.quantity,
                         'ProductInfo' : <subquery from product>
                         'ShipmentInfo' : <subquery from
shipments>

            })
                  FROM ORDER_ITEMS oi WITH INSERT, UPDATE
                  WHERE ord.order_id = oi.order_id)
}
FROM ORDERS ord WITH INSERT, UPDATE, DELETE;

```

## CREATE LIBRARY

### Purpose

Use the `CREATE LIBRARY` statement to create a schema object associated with an operating-system shared library. The name of this schema object can then be used in the `call_spec` of `CREATE FUNCTION` or `CREATE PROCEDURE` statements, or when declaring a function or procedure in a package or type, so that SQL and PL/SQL can call to third-generation-language (3GL) functions and procedures.

**See Also:**

[CREATE FUNCTION](#) and *Oracle Database PL/SQL Language Reference* for more information on functions and procedures

**Prerequisites**

The `CREATE LIBRARY` statement is valid only on platforms that support shared libraries and dynamic linking.

To create a library in your own schema, you must have the `CREATE LIBRARY` system privilege. To create a library in another user's schema, you must have the `CREATE ANY LIBRARY` system privilege.

To use the library in the `call_spec` of a `CREATE FUNCTION` statement, or when declaring a function in a package or type, you must have the `EXECUTE` object privilege on the library and the `CREATE FUNCTION` system privilege. Refer to *Oracle Database PL/SQL Language Reference* for information on the `call_spec` of a `CREATE FUNCTION` statement.

To use the library in the `call_spec` of a `CREATE PROCEDURE` statement, or when declaring a procedure in a package or type, you must have the `EXECUTE` object privilege on the library and the `CREATE PROCEDURE` system privilege. Refer to *Oracle Database PL/SQL Language Reference* for information on the `call_spec` of a `CREATE PROCEDURE` statement.

To execute a procedure or function defined with the `call_spec` (including a procedure or function defined within a package or type), you must have the `EXECUTE` object privilege on the procedure or function (but you do not need the `EXECUTE` object privilege on the library).

**Syntax**

Libraries are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

***create\_library::=***

(`plsql_library_source`: See *Oracle Database PL/SQL Language Reference*.)

**Semantics****OR REPLACE**

Specify `OR REPLACE` to re-create the library if it already exists. Use this clause to change the definition of an existing library without dropping, re-creating, and regranting object privileges granted on it.

Users who had previously been granted privileges on a redefined library can still access the library without being regranted the privileges.

#### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the library does not exist, a new library is created at the end of the statement.
- If the library exists, this is the library you have at the end of the statement. A new one is not created because the older one is detected.

You can have `one of OR REPLACE or IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error:  
`ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

#### [ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the library is an editioned or noneditioned object if editioning is enabled for the schema object type `LIBRARY` in `schema`. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

#### `plsql_library_source`

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the `plsql_library_source`.

## CREATE LOCKDOWN PROFILE

### Purpose

Use the `CREATE LOCKDOWN PROFILE` statement to create a PDB lockdown profile. You can use PDB lockdown profiles in a multitenant container database (CDB) to restrict user operations in PDBs.

After you create a PDB lockdown profile, you can add restrictions to the profile with the `ALTER LOCKDOWN PROFILE` statement. You can restrict user operations associated with certain database features, options, and SQL statements.

When a lockdown profile is assigned to a PDB, users in that PDB cannot perform the operations that are disabled for the profile. To assign a lockdown profile, set its name for the value of the `PDB_LOCKDOWN` initialization parameter. You can assign a lockdown profile to individual PDBs, or to all PDBs in a CDB or application container, as follows:

- If you set `PDB_LOCKDOWN` while connected to a CDB root, then the lockdown profile applies to all PDBs in the CDB. It does not apply to the CDB root.
- If you set `PDB_LOCKDOWN` while connected to an application root, then the lockdown profile applies to the application root and all PDBs in the application container.
- If you set `PDB_LOCKDOWN` while connected to a particular PDB, then the lockdown profile applies to that PDB and overrides the lockdown profile for the CDB or application container, if one exists.

 **See Also:**

- [ALTER LOCKDOWN PROFILE](#) and [DROP LOCKDOWN PROFILE](#)
- *Oracle Database Security Guide* for more information on PDB lockdown profiles

### Prerequisites

- The CREATE LOCKDOWN PROFILE statement must be issued from the CDB or the Application Root.
- You must have the CREATE LOCKDOWN PROFILE system privilege in the container in which the statement is issued.
- The PDB lockdown profile name must be unique in the container in which the statement is issued.

### Syntax

***create\_lockdown\_profile ::=***

***static\_base\_profile ::=***

***dynamic\_base\_profile ::=***

### Semantics

#### *profile\_name*

You can create a new PDB lockdown profile with a name that you specify. The name must satisfy the requirements listed in “[Database Object Naming Rules](#)”. The lockdown profile can be derived from a static, or dynamic base profile.

#### *static\_base\_profile*

Use this option to create a new lockdown profile with a base profile. The rules of the base profile in effect at profile creation time will be copied to the new lockdown profile.

Changes to the base profile after the lockdown profile is created will not apply to the lockdown profile.

### ***dynamic\_base\_profile***

Use this option to create a new lockdown profile that will change with changes to the base profile. The new lockdown profile will inherit `DISABLE` rules of the base profile as well and subsequent changes to the base profile. The rules of the base profile have precedence in any conflict with rules that may be explicitly added to the lockdown profile. For example, the `OPTION_VALUE` clause of the base profile takes precedence over the `OPTION_VALUE` clause of the dynamic base profile.

## Example

The following statement creates PDB lockdown profile `hr_prof` with a dynamic base profile `PRIVATE DBAAS`:

```
CREATE LOCKDOWN PROFILE hr prof INCLUDING PRIVATE DBAAS;
```

# CREATE LOGICAL PARTITION TRACKING

## Purpose

Use the CREATE LOGICAL PARTITION TRACKING statement to define a logical partitioning scheme on a table for being leveraged by materialized views and logical partition change tracking. You can define the logical partitions of your tables independently of any existing or non-existing partitioning schema of a table.

## Syntax

*create\_logical\_partition\_tracking::=*

## Semantics

Logical partition tracking is supported on a single key column within the table. The datatype of the key column can be of the following data types: NUMBER, DATE, CHAR, VARCHAR, VARCHAR2, TIMESTAMP, TIMSTAMP WITH TIME ZONE.

Only RANGE and INTERVAL logical partitions are supported on the base table.

 **See Also:**

- *Refreshing Materialized Views* of the *Data Warehousing Guide*.

## CREATE MATERIALIZED VIEW

### Purpose

Use the CREATE MATERIALIZED VIEW statement to create a **materialized view**. A materialized view is a database object that contains the results of a query. The FROM clause of the query can name tables, views, and other materialized views. Collectively these objects are called **master tables** (a replication term) or **detail tables** (a data warehousing term). This reference uses "master tables" for consistency. The databases containing the master tables are called the **master databases**.

 **Note:**

The keyword **SNAPSHOT** is supported in place of **MATERIALIZED VIEW** for backward compatibility.

For replication purposes, materialized views allow you to maintain read-only copies of remote data on your local node. You can select data from a materialized view as you would from a table or view. In replication environments, the materialized views commonly created are **primary key**, **rowid**, **object**, and **subquery** materialized views.

 **See Also:**

*Oracle Database Administrator's Guide* for information on the types of materialized views used to support replication

For data warehousing purposes, the materialized views commonly created are **materialized aggregate views**, **single-table materialized aggregate views**, and **materialized join views**. All three types of materialized views can be used by query rewrite, an optimization technique that transforms a user request written in terms of master tables into a semantically equivalent request that includes one or more materialized views.

 **See Also:**

- [ALTER MATERIALIZED VIEW](#)
- *Oracle Database Data Warehousing Guide* for information on the types of materialized views used to support data warehousing

## Prerequisites

The privileges required to create a materialized view should be granted directly rather than through a role.

To create a materialized view **in your own schema**:

- You must have been granted the CREATE MATERIALIZED VIEW system privilege **and** either the CREATE TABLE or CREATE ANY TABLE system privilege.
- You must also have access to any master tables of the materialized view that you do not own, either through a READ or SELECT object privilege on each of the tables or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

To create a materialized view **in another user's schema**:

- You must have the CREATE ANY MATERIALIZED VIEW system privilege.
- The owner of the materialized view must have the CREATE TABLE system privilege. The owner must also have access to any master tables of the materialized view that the schema owner does not own (for example, if the master tables are on a remote database) and to any materialized view logs defined on those master tables, either through a READ or SELECT object privilege on each of the tables or through the READ ANY TABLE or SELECT ANY TABLE system privilege.

To create a refresh-on-commit materialized view (`REFRESH ON COMMIT` clause), in addition to the preceding privileges, you must have the `ON COMMIT REFRESH` object privilege on any master tables that you do not own or you must have the `ON COMMIT REFRESH` system privilege.

To create the materialized view **with query rewrite enabled**, in addition to the preceding privileges:

- If the schema owner does not own the master tables, then the schema owner must have the GLOBAL QUERY REWRITE privilege or the QUERY REWRITE object privilege on each table outside the schema.
- If you are defining the materialized view on a prebuilt container (`ON PREBUILT TABLE` clause), then you must have the READ or SELECT privilege WITH GRANT OPTION on the container table.

The user whose schema contains the materialized view must have sufficient quota in the target tablespace to store the master table and index of the materialized view or must have the UNLIMITED TABLESPACE system privilege.

When you create a materialized view, Oracle Database creates one internal table and at least one index, and may create one view, all in the schema of the materialized view. Oracle Database uses these objects to maintain the materialized view data. You must have the privileges necessary to create these objects.

You can create the following types of local materialized views (including both `ON COMMIT` and `ON DEMAND`) on master tables with commit SCN-based materialized view logs:

- Materialized aggregate views, including materialized aggregate views on a single table
- Materialized join views
- Primary-key-based and rowid-based single table materialized views
- UNION ALL materialized views, where each UNION ALL branch is one of the above materialized view types

You cannot create remote materialized views on master tables with commit SCN-based materialized view logs.

Creating a materialized view on master tables with different types of materialized view logs (that is, a master table with timestamp-based materialized view logs and a master table with commit SCN-based materialized view logs) is not supported and causes ORA-32414.

To specify an edition in the `evaluation_edition_clause` or the `unusable_editions_clause`, you must have the `USE` privilege on the edition.

#### See Also:

- [CREATE TABLE](#), [CREATE VIEW](#), and [CREATE INDEX](#) for information on these privileges

## Semantics

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the view does not exist, a new view is created at the end of the statement.
- If the view exists, this is the view you have at the end of the statement. A new one is not created because the older one is detected.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

***annotations\_clause***

For the full semantics of the annotations clause see [annotations\\_clause](#).

***schema***

Specify the schema to contain the materialized view. If you omit *schema*, then Oracle Database creates the materialized view in your schema.

***materialized\_view***

Specify the name of the materialized view to be created. The name must satisfy the requirements listed in "Database Object Naming Rules ". Oracle Database generates names for the table and indexes used to maintain the materialized view by adding a prefix or suffix to the materialized view name.

***column\_alias***

You can specify a column alias for each column of the materialized view. The column alias list explicitly resolves any column name conflict, eliminating the need to specify aliases in the `SELECT` clause of the materialized view. If you specify any column alias in this clause, then you must specify an alias for each data source referenced in the `SELECT` clause.

***ENCRYPT clause***

Use this clause to encrypt this column of the materialized view. Refer to the `CREATE TABLE` clause [encryption\\_spec](#) for more information on column encryption.

***OF object\_type***

The `OF object_type` clause lets you explicitly create an **object materialized view** of type *object\_type*.

 **See Also:**

See `CREATE TABLE ... object_table` for more information on the `OF type_name` clause

***scoped\_table\_ref\_constraint***

Use the `SCOPE FOR` clause to restrict the scope of references to a single object table. You can refer either to the table name with *scope\_table\_name* or to a column alias. The values in the `REF` column or attribute point to objects in *scope\_table\_name* or *c\_alias*, in which object instances of the same type as the `REF` column are stored. If you specify aliases, then they must have a one-to-one correspondence with the columns in the `SELECT` list of the defining query of the materialized view.

 **See Also:**

"[SCOPE REF Constraints](#)" for more information

## DEFAULT COLLATION

Use this clause to specify the default collation for the materialized view. The default collation is used as the derived collation for all the character literals included in the defining query of the materialized view. The default collation is not used by the materialized view columns; the collations for the materialized view columns are derived from the materialized view's defining subquery. The `CREATE MATERIALIZED VIEW` statement fails with an error, or the materialized view is created in an invalid state, if any of its character columns is based on an expression in the defining subquery that has no derived collation.

For `collation_name`, specify a valid named collation or pseudo-collation.

If you omit this clause, then the default collation for the materialized view is set to the effective schema default collation of the schema containing the materialized view. Refer to the `DEFAULT_COLLATION` clause of `ALTER SESSION` for more information on the effective schema default collation.

You can specify the `DEFAULT COLLATION` clause only if the `COMPATIBLE` initialization parameter is set to 12.2 or greater, and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`.

To change the default collation for a materialized view, you must recreate the materialized view.

### Restrictions on the Default Collation for Materialized Views

The following restrictions apply when specifying the default collation for a materialized view:

- If the defining query of the materialized view contains the `WITH plsql_declarations` clause, then the default collation of the materialized view must be `USING_NLS_COMP`.
- If the materialized view is created on a prebuilt table, then the declared collations of the table columns must be the same as the corresponding collations of the materialized view columns, as derived from the defining query.

## ON PREBUILT TABLE Clause

The `ON PREBUILT TABLE` clause lets you register an existing table as a preinitialized materialized view. This clause is particularly useful for registering large materialized views in a data warehousing environment. The table must have the same name and be in the same schema as the resulting materialized view.

If the materialized view is dropped, then the preexisting table reverts to its identity as a table.

### Note:

This clause assumes that the table object reflects the materialization of a subquery. Oracle strongly recommends that you ensure that this assumption is true in order to ensure that the materialized view correctly reflects the data in its master tables.

The `ON PREBUILT TABLE` clause could be useful in the following scenarios:

- You have a table representing the result of a query. Creating the table was an expensive operation that possibly took a long time. You want to create a materialized view on the query. You can use the `ON PREBUILT TABLE` clause to avoid the expense of executing the query and populating the container for the materialized view.

- You temporarily discontinue having a materialized view, but keep its container table, using the `DROP MATERIALIZED VIEW ... PRESERVE TABLE` statement. You then decide to recreate the materialized view and you know that the master tables of the view have not changed. You can create the materialized view using the `ON PREBUILT TABLE` clause. This avoids the expense and time of creating and populating the container table for the materialized view.

If you specify `ON PREBUILT TABLE`, then Oracle database does not create the `I_SNAPS$` index. This index improves fast refresh performance. If you want the benefits of this index, then you can create it manually. Refer to *Oracle Database Data Warehousing Guide* for more information.

#### WITH REDUCED PRECISION

Specify `WITH REDUCED PRECISION` to authorize the loss of precision that will result if the precision of the table or materialized view columns do not exactly match the precision returned by `subquery`.

#### WITHOUT REDUCED PRECISION

Specify `WITHOUT REDUCED PRECISION` to require that the precision of the table or materialized view columns match exactly the precision returned by `subquery`, or the create operation will fail. This is the default.

#### Restrictions on Using Prebuilt Tables

Prebuilt tables are subject to the following restrictions:

- Each column alias in `subquery` must correspond to a column in the prebuilt table, and corresponding columns must have matching data types.
- If you specify this clause, then you cannot specify a `NOT NULL` constraint for any column that is not referenced in `subquery` unless you also specify a default value for that column.
- You cannot specify the `ON PREBUILT TABLE` clause when creating a rowid materialized view.

#### See Also:

["Creating Prebuilt Materialized Views: Example"](#)

#### `physical_properties_clause`

The components of the `physical_properties_clause` have the same semantics for materialized views that they have for tables, with exceptions and additions described in the sections that follow.

#### Restriction on the `physical_properties_clause`

You cannot specify `ORGANIZATION EXTERNAL` for a materialized view.

#### `deferred_segment_creation`

Use this clause to determine when the segment for this materialized view should be created. See the `CREATE TABLE` clause [`deferred\_segment\_creation`](#) for more information.

***segment\_attributes\_clause***

Use the *segment\_attributes\_clause* to establish values for the PCTFREE, PCTUSED, and INITTRANS parameters, the storage characteristics for the materialized view, to assign a tablespace, and to specify whether logging is to occur. In the USING INDEX clause, you cannot specify PCTFREE or PCTUSED.

**TABLESPACE Clause**

Specify the tablespace in which the materialized view is to be created. If you omit this clause, then Oracle Database creates the materialized view in the default tablespace of the schema containing the materialized view.

 **See Also:**

[physical\\_attributes\\_clause](#) and [storage\\_clause](#) for a complete description of these clauses, including default values

***logging\_clause***

Specify LOGGING or NOLOGGING to establish the logging characteristics for the materialized view. The logging characteristic affects the creation of the materialized view and any nonatomic refresh that is initiated by way of the DBMS\_REFRESH package. The default is the logging characteristic of the tablespace in which the materialized view resides.

 **See Also:**

[logging\\_clause](#) for a full description of this clause and *Oracle Database PL/SQL Packages and Types Reference* for more information on atomic and nonatomic refresh

***table\_compression***

Use the *table\_compression* clause to instruct the database whether to compress data segments to reduce disk and memory use. This clause has the same semantics in CREATE MATERIALIZED VIEW and CREATE TABLE. Refer to the [table\\_compression](#) clause in the documentation on CREATE TABLE for the full semantics of this clause.

***inmemory\_table\_clause***

Use the *inmemory\_table\_clause* to enable or disable the materialized view for the In-Memory Column Store (IM column store). This clause has the same semantics as the [inmemory\\_table\\_clause](#) in the CREATE TABLE documentation.

***inmemory\_column\_clause***

Use the *inmemory\_column\_clause* to disable specific materialized view columns for the IM column store, and to specify the data compression method for specific columns. This clause has the same semantics here as it has for the [inmemory\\_column\\_clause](#) in the CREATE TABLE

documentation, with the following addition: If you specify the *inmemory\_column\_clause*, then you must also specify a *column\_alias* for each column in the materialized view.

#### ***index\_org\_table\_clause***

The ORGANIZATION INDEX clause lets you create an index-organized materialized view. In such a materialized view, data rows are stored in an index defined on the primary key of the materialized view. You can specify index organization for the following types of materialized views:

- Read-only and updatable object materialized views. You must ensure that the master table has a primary key.
- Read-only and updatable primary key materialized views.
- Read-only rowid materialized views.

The keywords and parameters of the *index\_org\_table\_clause* have the same semantics as described in CREATE TABLE, with the restrictions that follow.

#### **See Also:**

The *index\_org\_table\_clause* of CREATE TABLE

### **Restrictions on Index-Organized Materialized Views**

Index-organized materialized views are subject to the following restrictions:

- You cannot specify the following CREATE MATERIALIZED VIEW clauses: CACHE or NOCACHE, CLUSTER, or ON PREBUILT TABLE.
- In the *index\_org\_table\_clause*:
  - You cannot specify the *mapping\_table\_clause*.
  - You can specify COMPRESS only for a materialized view based on a composite primary key. You can specify NOCOMPRESS for a materialized view based on either a simple or composite primary key.

### **CLUSTER Clause**

The CLUSTER clause lets you create the materialized view as part of the specified cluster. A cluster materialized view uses the space allocation of the cluster. Therefore, you do not specify physical attributes or the TABLESPACE clause with the CLUSTER clause.

### **Restriction on Cluster Materialized Views**

If you specify CLUSTER, then you cannot specify the *table\_partitioning\_clauses* in *materialized\_view\_props*.

#### ***materialized\_view\_props***

Use these property clauses to describe a materialized view that is not based on an existing table. To create a materialized view that is based on an existing table, use the ON PREBUILT TABLE clause.

### ***column\_properties***

The *column\_properties* clause lets you specify the storage characteristics of a LOB, nested table, varray, or XMLType column. The *object\_type\_col\_properties* are not relevant for a materialized view.

 **See Also:**

[CREATE TABLE](#) for detailed information about specifying the parameters of this clause

### ***table\_partitioning\_clauses***

The *table\_partitioning\_clauses* let you specify that the materialized view is partitioned on specified ranges of values or on a hash function. Partitioning of materialized views is the same as partitioning of tables.

 **See Also:**

[table\\_partitioning\\_clauses](#) in the CREATE TABLE documentation

### **CACHE | NOCACHE**

For data that will be accessed frequently, CACHE specifies that the blocks retrieved for this table are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables. NOCACHE specifies that the blocks are placed at the least recently used end of the LRU list.

 **Note:**

NOCACHE has no effect on materialized views for which you specify *KEEP* in the *storage\_clause*.

 **See Also:**

[CREATE TABLE](#) for information about specifying CACHE or NOCACHE

### ***parallel\_clause***

The *parallel\_clause* lets you indicate whether parallel operations will be supported for the materialized view and sets the default degree of parallelism for queries and DML on the materialized view after creation.

For complete information on this clause, refer to [parallel\\_clause](#) in the documentation on CREATE TABLE.

***build\_clause***

The *build\_clause* lets you specify when to populate the materialized view.

**IMMEDIATE**

Specify **IMMEDIATE** to indicate that the materialized view is to be populated immediately. This is the default.

**DEFERRED**

Specify **DEFERRED** to indicate that the materialized view is to be populated by the next **REFRESH** operation. The first (deferred) refresh must always be a complete refresh. Until then, the materialized view has a staleness value of **UNUSABLE**, so it cannot be used for query rewrite.

**USING INDEX Clause**

The **USING INDEX** clause lets you establish the value of the **INITTRANS** and **STORAGE** parameters for the default index Oracle Database uses to maintain the materialized view data. If **USING INDEX** is not specified, then default values are used for the index. Oracle Database uses the default index to speed up incremental (**FAST**) refresh of the materialized view.

**Restriction on USING INDEX clause**

You cannot specify the **PCTUSED** parameter in this clause.

**USING NO INDEX Clause**

Specify **USING NO INDEX** to suppress the creation of the default index. You can create an alternative index explicitly by using the **CREATE INDEX** statement. You should create such an index if you specify **USING NO INDEX** and you are creating the materialized view with the fast refresh method (**REFRESH FAST**).

***create\_mv\_refresh***

Use the *create\_mv\_refresh* clause to specify the default methods, modes, and times for the database to refresh the materialized view. If the master tables of a materialized view are modified, then the data in the materialized view must be updated to make the materialized view accurately reflect the data currently in its master tables. This clause lets you schedule the times and specify the method and mode for the database to refresh the materialized view.

**Restriction on Synchronous Refresh**

If you are using the synchronous refresh method, then you must specify **ON DEMAND** and **USING TRUSTED CONSTRAINTS**.

 **Note:**

This clause only sets the default refresh options. For instructions on actually implementing the refresh, refer to *Oracle Database Administrator's Guide* and *Oracle Database Data Warehousing Guide*.

 **See Also:**

- "[Periodic Refresh of Materialized Views: Example](#)" and "[Automatic Refresh Times for Materialized Views: Example](#)"
- *Oracle Database PL/SQL Packages and Types Reference* for more information on refresh methods
- *Oracle Database Data Warehousing Guide* to learn how to use refresh statistics to monitor the performance of materialized view refresh operations

**FAST Clause**

Specify `FAST` to indicate the fast refresh method, which performs the refresh according to the changes that have occurred to the master tables. The changes for conventional DML changes are stored in the materialized view log associated with the master table. The changes for direct-path `INSERT` operations are stored in the direct loader log.

If you specify `REFRESH FAST`, then the `CREATE` statement will fail unless materialized view logs already exist for the materialized view master tables. Oracle Database creates the direct loader log automatically when a direct-path `INSERT` takes place. No user intervention is needed.

For both conventional DML changes and for direct-path `INSERT` operations, other conditions may restrict the eligibility of a materialized view for fast refresh.

**Restrictions on FAST Refresh**

`FAST` refresh is subject to the following restrictions:

- When you specify `FAST` refresh at create time, Oracle Database verifies that the materialized view you are creating is eligible for fast refresh. When you change the refresh method to `FAST` in an `ALTER MATERIALIZED VIEW` statement, Oracle Database does not perform this verification. If the materialized view is not eligible for fast refresh, then Oracle Database returns an error when you attempt to refresh this view.
- Materialized views are not eligible for fast refresh if the defining query contains an analytic function or the `XMLETable` function.
- Materialized views are not eligible for fast refresh if the defining query references a table on which an `XMLIndex` index is defined.
- You cannot fast refresh a materialized view if any of its columns is encrypted.

 **See Also:**

- *Oracle Database Administrator's Guide* for restrictions on fast refresh in replication environments
- *Oracle Database Data Warehousing Guide* for restrictions on fast refresh in data warehousing environments
- The `EXPLAIN_MVIEW` procedure of the `DBMS_MVIEW` package for help diagnosing problems with fast refresh and the `TUNE_MVIEW` procedure of the `DBMS_MVIEW` package for correction of query rewrite problems
- "[Analytic Functions](#)"
- "[Creating a Fast Refreshable Materialized View: Example](#)"

**COMPLETE Clause**

Specify `COMPLETE` to indicate the complete refresh method, which is implemented by executing the defining query of the materialized view. If you request a complete refresh, then Oracle Database performs a complete refresh even if a fast refresh is possible.

**FORCE Clause**

Specify `FORCE` to indicate that when a refresh occurs, Oracle Database will perform a fast refresh if one is possible or a complete refresh if fast refresh is not possible. If you do not specify a refresh method (`FAST`, `COMPLETE`, or `FORCE`), then `FORCE` is the default.

**ON COMMIT Clause**

Specify `ON COMMIT` to indicate that a refresh is to occur whenever the database commits a transaction that operates on a master table of the materialized view. This clause may increase the time taken to complete the commit, because the database performs the refresh operation as part of the commit process.

You can specify only one of the `ON COMMIT`, `ON DEMAND`, and `ON STATEMENT` clauses. If you specify `ON COMMIT`, then you cannot also specify `START WITH` or `NEXT`.

**Restrictions on Refreshing ON COMMIT**

The following restrictions apply to the `ON COMMIT` clause:

- This clause is not supported for materialized views containing object types or Oracle-supplied types.
- This clause is not supported for materialized views with remote tables.
- If you specify this clause, then you cannot subsequently execute a distributed transaction on any master table of this materialized view. For example, you cannot insert into the master by selecting from a remote table. The `ON DEMAND` clause does not impose this restriction on subsequent distributed transactions on master tables.

**ON DEMAND Clause**

Specify `ON DEMAND` to indicate that database will not refresh the materialized view unless the user manually launches a refresh through one of the three `DBMS_MVIEW` refresh procedures.

You can specify only one of the `ON COMMIT`, `ON DEMAND`, and `ON STATEMENT` clauses. If you omit all three of these clauses, then `ON DEMAND` is the default. You can override this default setting by specifying the `START WITH` or `NEXT` clauses, either in the same `CREATE MATERIALIZED VIEW` statement or a subsequent `ALTER MATERIALIZED VIEW` statement.

`START WITH` and `NEXT` take precedence over `ON DEMAND`. Therefore, in most circumstances it is not meaningful to specify `ON DEMAND` when you have specified `START WITH` or `NEXT`.

### See Also:

- *Oracle Database PL/SQL Packages and Types Reference* for information on these procedures
- *Oracle Database Data Warehousing Guide* on the types of materialized views you can create by specifying `REFRESH ON DEMAND`

## ON STATEMENT Clause

Specify `ON STATEMENT` to indicate that an automatic refresh is to occur every time a DML operation is performed on any of the materialized view's base tables.

You can specify only one of the `ON COMMIT`, `ON DEMAND`, and `ON STATEMENT` clauses. You can specify `ON STATEMENT` only when *creating* a materialized view. You cannot subsequently *alter* the materialized view to use `ON STATEMENT` refresh.

### Restrictions on Refreshing ON STATEMENT

The following restrictions apply to the `ON STATEMENT` clause:

- This clause can be used only with materialized views that are fast refreshable. The `ON STATEMENT` clause must be specified with the `REFRESH FAST` clause.
- The base tables referenced in the materialized view's defining query must be connected in a join graph that uses the star schema or snowflake schema model. The query must contain exactly one centralized fact table and one or more dimension tables, with all pairs of joined tables being related using primary key-foreign key constraints.
  - There is no restriction on the depth of the snowflake model.
  - The constraints can be in `RELY` mode. However, you must include the `USING TRUSTED CONSTRAINT` clause while creating the materialized view to use the `RELY` constraint.
- The materialized view's defining query must include the `ROWID` column of the fact table.
- The materialized view's defining query cannot include any of the following: invisible columns, ANSI join syntax, complex query, inline view as base table, composite primary key, `LONG` columns, and LOB columns.
- You cannot alter the definition of an existing materialized view that uses the `ON STATEMENT` refresh mode.
- You cannot alter an existing materialized view and enable `ON STATEMENT` refresh for it.

- The following operations cause a materialized view with `ON STATEMENT` refresh to become unusable:
  - `UPDATE` operations on one or more dimension tables on which the materialized view is based
  - Partition maintenance operations and `TRUNCATE` operations on any base table
- However, a materialized view with the `ON STATEMENT` refresh mode can be partitioned.
- All the restrictions that apply to the `ON COMMIT` clause apply to `ON STATEMENT`.

### START WITH Clause

Specify a datetime expression for the first automatic refresh time.

### NEXT Clause

Specify a datetime expression for calculating the interval between automatic refreshes.

Both the `START WITH` and `NEXT` values must evaluate to a time in the future. If you omit the `START WITH` value, then the database determines the first automatic refresh time by evaluating the `NEXT` expression with respect to the creation time of the materialized view. If you specify a `START WITH` value but omit the `NEXT` value, then the database refreshes the materialized view only once. If you omit both the `START WITH` and `NEXT` values, or if you omit the `create_mv_refresh` entirely, then the database does not automatically refresh the materialized view.

### WITH PRIMARY KEY Clause

Specify `WITH PRIMARY KEY` to create a primary key materialized view. This is the default and should be used in all cases except those described for `WITH ROWID`. Primary key materialized views allow materialized view master tables to be reorganized without affecting the eligibility of the materialized view for fast refresh. The master table must contain an enabled primary key constraint, and the defining query of the materialized view must specify all of the primary key columns directly. In the defining query, the primary key columns cannot be specified as the argument to a function such as `UPPER`.

### Restriction on Primary Key Materialized Views

You cannot specify this clause for an object materialized view. Oracle Database implicitly refreshes objects materialized `WITH OBJECT ID`.

#### See Also:

*Oracle Database Administrator's Guide* for detailed information about primary key materialized views and "[Creating Primary Key Materialized Views: Example](#)"

### WITH ROWID Clause

Specify `WITH ROWID` to create a rowid materialized view. Rowid materialized views are useful if the materialized view does not include all primary key columns of the master tables. Rowid materialized views must be based on a single table and cannot contain any of the following:

- Distinct or aggregate functions
- GROUP BY or CONNECT BY clauses
- Subqueries
- Joins
- Set operations

The WITH ROWID clause has no effect if there are multiple master tables in the defining query.

Rowid materialized views are not eligible for fast refresh after a master table reorganization until a complete refresh has been performed.

#### Restriction on Rowid Materialized Views

You cannot specify this clause for an object materialized view. Oracle Database implicitly refreshes objects materialized WITH OBJECT ID.

#### See Also:

["Creating Materialized Aggregate Views: Example"](#) and ["Creating Rowid Materialized Views: Example"](#)

### USING ROLLBACK SEGMENT Clause

This clause is not valid if your database is in automatic undo mode, because in that mode Oracle Database uses undo tablespaces instead of rollback segments. Oracle strongly recommends that you use automatic undo mode. This clause is supported for backward compatibility with replication environments containing older versions of Oracle Database that still use rollback segments.

For *rollback\_segment*, specify the remote rollback segment to be used during materialized view refresh.

#### DEFAULT

DEFAULT specifies that Oracle Database will choose automatically which rollback segment to use. If you specify DEFAULT, then you cannot specify *rollback\_segment*. DEFAULT is most useful when modifying, rather than creating, a materialized view.

#### See Also:

[ALTER MATERIALIZED VIEW](#)

#### MASTER

MASTER specifies the remote rollback segment to be used at the remote master site for the individual materialized view.

#### LOCAL

LOCAL specifies the remote rollback segment to be used for the local refresh group that contains the materialized view. This is the default.

 **See Also:**

*Oracle Database PL/SQL Packages and Types Reference* for information on specifying the local materialized view rollback segment using the DBMS\_REFRESH package

If you omit `rollback_segment`, then the database automatically chooses the rollback segment to be used. One master rollback segment is stored for each materialized view and is validated during materialized view creation and refresh. If the materialized view is complex, then the database ignores any master rollback segment you specify.

#### **USING ... CONSTRAINTS Clause**

The USING ... CONSTRAINTS clause lets Oracle Database choose more rewrite options during the refresh operation, resulting in more efficient refresh execution. The clause lets Oracle Database use unenforced constraints, such as dimension relationships or constraints in the RELY state, rather than relying only on enforced constraints during the refresh operation.

The USING TRUSTED CONSTRAINTS clause enables you to create a materialized view on top of a table that has a non-NULL Virtual Private Database (VPD) policy on it. In this case, you must ensure that the materialized view behaves correctly. Materialized view results are computed based on the rows and columns filtered by VPD policy. Therefore, you must coordinate the materialized view definition with the VPD policy to ensure the correct results. Without the USING TRUSTED CONSTRAINTS clause, any VPD policy on a master table will prevent a materialized view from being created.

 **Note:**

The USING TRUSTED CONSTRAINTS clause lets Oracle Database use dimension and constraint information that has been declared trustworthy by the database administrator but that has not been validated by the database. If the dimension and constraint information is valid, then performance may improve. However, if this information is invalid, then the refresh procedure may corrupt the materialized view even though it returns a success status.

If you omit this clause, then the default is USING ENFORCED CONSTRAINTS.

#### **NEVER REFRESH Clause**

Specify NEVER REFRESH to prevent the materialized view from being refreshed with any Oracle Database refresh mechanism or packaged procedure. Oracle Database will ignore any REFRESH statement on the materialized view issued from such a procedure. If you specify this clause, then you can perform DML operations on the materialized view. To reverse this clause, you must issue an ALTER MATERIALIZED VIEW ... REFRESH statement.

### ***evaluation\_edition\_clause***

You must specify this clause if *subquery* references an editioned object. Use this clause to specify the edition that is searched during name resolution of the editioned object—the evaluation edition.

- Specify CURRENT EDITION to search the edition in which this DDL statement is executed.
- Specify EDITION *edition* to search *edition*.
- Specifying NULL EDITION is equivalent to omitting the *evaluation\_edition\_clause*.

If you omit the *evaluation\_edition\_clause*, then editioned objects are invisible during name resolution and an error will result. Dropping the evaluation edition invalidates the materialized view.

#### **See Also:**

*Oracle Database Development Guide* for more information on specifying the evaluation edition for a materialized view

### **{ ENABLE | DISABLE } ON QUERY COMPUTATION**

This clause lets you create a real-time materialized view or a regular view. A real-time materialized view provides fresh data to user queries even when the materialized view is not in sync with its base tables due to data changes. Instead of modifying the materialized view, the optimizer writes a query that combines the existing rows in the materialized view with changes recorded in log files (either materialized view logs or the direct loader logs). This is called on-query computation.

- Specify ENABLE ON QUERY COMPUTATION to create a real-time materialized view by enabling on-query computation. This allows you to directly query up-to-date data from the materialized view by specifying the FRESH\_MV hint in the SELECT statement. If the materialized view is also enabled for query rewrite, then on-query computation occurs automatically during query rewrite.
- Specify DISABLE ON QUERY COMPUTATION to create a regular materialized view by disabling on-query computation. This is the default.

### **Restrictions on Real-Time Materialized Views**

Real-time materialized views are subject to the following restrictions:

- Real-time materialized views cannot be used when one or more materialized view logs created on the base tables are either unusable or nonexistent.
- A real-time materialized view must be refreshable using out-of-place refresh, log-based refresh, or partition change tracking (PCT) refresh.
- A refresh-on-commit materialized view cannot be a real-time materialized view.
- If a real-time materialized view is a nested materialized view that is defined on top of one or more base materialized views, then query rewrite occurs only if all the base materialized views are fresh. If one or more base materialized views are stale, then query rewrite is not performed using this real-time materialized view.
- The cursors of queries that directly access real-time materialized views are not shared.

 **See Also:**

- [FRESH\\_MV Hint](#)
- [Oracle Database Data Warehousing Guide](#) for more information on real-time materialized views

***query\_rewrite\_clause***

The *query\_rewrite\_clause* lets you specify whether the materialized view is eligible to be used for query rewrite.

**ENABLE Clause**

Specify `ENABLE` to enable the materialized view for query rewrite. If you also specify the *unusable\_editions\_clause*, then the materialized view is not enabled for query rewrite in the unusable editions.

**Restrictions on Enabling Query Rewrite**

Enabling of query rewrite is subject to the following restrictions:

- You can enable query rewrite only if all user-defined functions in the materialized view are `DETERMINISTIC`.
- You can enable query rewrite only if expressions in the statement are repeatable. For example, you cannot include `CURRENT_TIME` or `USER`, sequence values (such as the `CURRVAL` or `NEXTVAL` pseudocolumns), or the `SAMPLE` clause (which may sample different rows as the contents of the materialized view change).

 **Note:**

- Query rewrite is disabled by default, so you must specify this clause to make materialized views eligible for query rewrite.
- After you create the materialized view, you must collect statistics on it using the `DBMS_STATS` package. Oracle Database needs the statistics generated by this package to optimize query rewrite.

### See Also:

- *Oracle Database Data Warehousing Guide* for more information on query rewrite
- *Oracle Database Data Warehousing Guide* to learn how to use refresh statistics to monitor the performance of materialized view refresh operations
- *Oracle Database PL/SQL Packages and Types Reference* for information about the DBMS\_STATS package
- The EXPLAIN\_MVIEW procedure of the DBMS\_MVIEW package for help diagnosing problems with query rewrite and the TUNE\_MVIEW procedure of the DBMS\_MVIEW package for correction of query rewrite problems
- [CREATE FUNCTION](#)

### **DISABLE Clause**

Specify `DISABLE` to indicate that the materialized view is not eligible for use by query rewrite. A disabled materialized view can be refreshed.

#### ***unusable\_editions\_clause***

This clause lets you specify that the materialized view is not eligible for query rewrite in one or more editions. You can specify this clause regardless of whether you specify the `ENABLE` or `DISABLE` clause. If you specify the `DISABLE` clause, then this clause will take effect if the materialized view is subsequently enabled for query rewrite using the `ALTER MATERIALIZED VIEW ... ENABLE QUERY REWRITE` statement.

#### **UNUSABLE BEFORE Clause**

This clause lets you specify that the materialized view is not eligible for query rewrite in the ancestors of an edition.

- If you specify `CURRENT EDITION`, then the materialized view is not eligible for query rewrite in the ancestors of the current edition.
- If you specify `EDITION edition`, then the materialized view is not eligible for query rewrite in the ancestors of the specified `edition`.

#### **UNUSABLE BEGINNING WITH Clause**

This clause lets you specify that the materialized view is not eligible for query rewrite in an edition and its descendants.

- If you specify `CURRENT EDITION`, then the materialized view is not eligible for query rewrite in the current edition and its descendants.
- If you specify `EDITION edition`, then the materialized view is not eligible for query rewrite in the specified edition and its descendants.
- Specifying `NONE EDITION` is equivalent to omitting the `UNUSABLE BEGINNING WITH` clause.

The materialized view has a dependency on each edition in which it is not eligible for query rewrite. If such an edition is subsequently dropped, then the dependency is removed. However, the materialized view is not invalidated.

## ENABLE | DISABLE CONCURRENT REFRESH

Enable concurrent refresh to refresh the same on-commit atomic materialized view across multiple sessions concurrently. The materialized view is refreshed concurrently when multiple concurrent DML transactions on the same base table of the materialized view are committed.

There are no limitations on how many materialized views can be refreshed.

Concurrent refresh is disabled by default. You must explicitly enable it on the materialized view. Note that you can enable it only on on-commit materialized views.

### See Also:

*Refreshing Materialized Views of the Oracle Database Data Warehousing Guide.*

## AS subquery

Specify the defining query of the materialized view. When you create the materialized view, Oracle Database executes this subquery and places the results in the materialized view. This subquery is any valid SQL subquery. However, not all subqueries are fast refreshable, nor are all subqueries eligible for query rewrite.

### Notes on the Defining Query of a Materialized View

The following notes apply to materialized views:

- Oracle Database does not execute the defining query immediately if you specify `BUILD DEFERRED`.
- Oracle recommends that you qualify each table and view in the `FROM` clause of the defining query of the materialized view with the schema containing it.
- In order to create a materialized view whose defining query selects from a master table that has a Virtual Private Database (VPD) policy, you must specify the `REFRESH USING TRUSTED CONSTRAINTS` clause.

### Restrictions on the Defining Query of a Materialized View

The materialized view query is subject to the following restrictions:

- The defining query of a materialized view can select from tables, views, or materialized views owned by the user `SYS`, but you cannot enable `QUERY REWRITE` on such a materialized view.
- The defining query of a materialized view cannot select from a `V$` view or a `GV$` view.
- You cannot define a materialized view with a subquery in the select list of the defining query. You can, however, include subqueries elsewhere in the defining query, such as in the `WHERE` clause.
- You cannot use the `AS OF` clause of the `flashback_query_clause` in the defining query of a materialized view.

- Materialized join views and materialized aggregate views with a GROUP BY clause cannot select from an index-organized table.
- Materialized views cannot contain columns of data type LONG or LONG RAW.
- Materialized views cannot contain virtual columns.
- You cannot create a materialized view log on a temporary table. Therefore, if the defining query references a temporary table, then this materialized view will not be eligible for FAST refresh, nor can you specify the QUERY REWRITE clause in this statement.
- If the FROM clause of the defining query references another materialized view, then you must always refresh the materialized view referenced in the defining query before refreshing the materialized view you are creating in this statement.
- Materialized views with join expressions in the defining query cannot have XML data type columns. The XML data types include XMLType and URI data type columns.

If you are creating a materialized view enabled for query rewrite, then:

- The defining query cannot contain, either directly or through a view, references to ROWNUM, USER, SYSDATE, remote tables, sequences, or PL/SQL functions that write or read database or package state.
- Neither the materialized view nor the master tables of the materialized view can be remote.

If you want the materialized view to be eligible for fast refresh using a materialized view log, or synchronous refresh using a staging log, then some additional restrictions apply.

#### See Also:

- *Oracle Database Data Warehousing Guide* for restrictions relating to using fast refresh and synchronous refresh
- *Oracle Database Administrator's Guide* for more information on restrictions relating to replication
- "[Creating Materialized Join Views: Example](#)", "[Creating Subquery Materialized Views: Example](#)", and "[Creating a Nested Materialized View: Example](#)"

## Examples

The following examples require the materialized logs that are created in the "Examples" section of [CREATE MATERIALIZED VIEW LOG](#).

### Creating a Simple Materialized View: Example

The following statement creates a very simple materialized view based on the employees and table in the hr schema:

```
CREATE MATERIALIZED VIEW mv1 AS SELECT * FROM hr.employees;
```

By default, Oracle Database creates a primary key materialized view with refresh on demand only. If a materialized view log exists on employees, then mv1 can be altered to be capable of fast refresh. If no such log exists, then only full refresh of mv1 is possible. Oracle Database uses default storage properties for mv1. The only privileges required for this operation are the

CREATE MATERIALIZED VIEW system privilege, and the READ or SELECT object privilege on hr.employees.

### **Creating Subquery Materialized Views: Example**

The following statement creates a subquery materialized view based on the customers and countries tables in the sh schema at the remote database:

```
CREATE MATERIALIZED VIEW foreign_customers
  AS SELECT * FROM sh.customers@remote cu
  WHERE EXISTS
    (SELECT * FROM sh.countries@remote co
     WHERE co.country_id = cu.country_id);
```

### **Creating Materialized Aggregate Views: Example**

The following statement creates and populates a materialized aggregate view on the sample sh.sales table and specifies the default refresh method, mode, and time. It uses the materialized view log created in "[Creating a Materialized View Log for Fast Refresh: Examples](#)", as well as the two additional logs shown here:

```
CREATE MATERIALIZED VIEW LOG ON times
  WITH ROWID, SEQUENCE (time_id, calendar_year)
  INCLUDING NEW VALUES;

CREATE MATERIALIZED VIEW LOG ON products
  WITH ROWID, SEQUENCE (prod_id)
  INCLUDING NEW VALUES;

CREATE MATERIALIZED VIEW sales_mv
  BUILD IMMEDIATE
  REFRESH FAST ON COMMIT
  AS SELECT t.calendar_year, p.prod_id,
    SUM(s.amount_sold) AS sum_sales
    FROM times t, products p, sales s
    WHERE t.time_id = s.time_id AND p.prod_id = s.prod_id
    GROUP BY t.calendar_year, p.prod_id;
```

### **Creating Materialized Join Views: Example**

The following statement creates and populates the materialized aggregate view sales\_by\_month\_by\_state using tables in the sample sh schema. The materialized view will be populated with data as soon as the statement executes successfully. By default, subsequent refreshes will be accomplished by reexecuting the defining query of the materialized view:

```
CREATE MATERIALIZED VIEW sales_by_month_by_state
  TABLESPACE example
  PARALLEL 4
  BUILD IMMEDIATE
  REFRESH COMPLETE
  ENABLE QUERY REWRITE
  AS SELECT t.calendar_month_desc, c.cust_state_province,
    SUM(s.amount_sold) AS sum_sales
    FROM times t, sales s, customers c
    WHERE s.time_id = t.time_id AND s.cust_id = c.cust_id
    GROUP BY t.calendar_month_desc, c.cust_state_province;
```

### **Creating Prebuilt Materialized Views: Example**

The following statement creates a materialized aggregate view for the preexisting summary table, `sales_sum_table`:

```
CREATE TABLE sales_sum_table
  (month VARCHAR2(8), state VARCHAR2(40), sales NUMBER(10,2));

CREATE MATERIALIZED VIEW sales_sum_table
  ON PREBUILT TABLE WITH REDUCED PRECISION
  ENABLE QUERY REWRITE
  AS SELECT t.calendar_month_desc AS month,
            c.cust_state_province AS state,
            SUM(s.amount_sold) AS sales
      FROM times t, customers c, sales s
     WHERE s.time_id = t.time_id AND s.cust_id = c.cust_id
   GROUP BY t.calendar_month_desc, c.cust_state_province;
```

In the preceding example, the materialized view has the same name and also has the same number of columns with the same data types as the prebuilt table. The `WITH REDUCED PRECISION` clause allows for differences between the precision of the materialized view columns and the precision of the values returned by the subquery.

### **Creating Primary Key Materialized Views: Example**

The following statement creates the primary key materialized view `catalog` on the sample table `oe.product_information`:

```
CREATE MATERIALIZED VIEW catalog
  REFRESH FAST START WITH SYSDATE NEXT SYSDATE + 1/4096
  WITH PRIMARY KEY
  AS SELECT * FROM product_information;
```

### **Creating Rowid Materialized Views: Example**

The following statement creates a rowid materialized view on the sample table `oe.orders`:

```
CREATE MATERIALIZED VIEW order_data REFRESH WITH ROWID
  AS SELECT * FROM orders;
```

### **Periodic Refresh of Materialized Views: Example**

The following statement creates the primary key materialized view `emp_data` and populates it with data from the sample table `hr.employees`:

```
CREATE MATERIALIZED VIEW LOG ON employees
  WITH PRIMARY KEY
  INCLUDING NEW VALUES;

CREATE MATERIALIZED VIEW emp_data
  PCTFREE 5 PCTUSED 60
  TABLESPACE example
  STORAGE (INITIAL 50K)
  REFRESH FAST NEXT sysdate + 7
  AS SELECT * FROM employees;
```

The preceding statement does not include a `START WITH` parameter, so Oracle Database determines the first automatic refresh time by evaluating the `NEXT` value using the current `SYSDATE`. A materialized view log was created for the employee table, so Oracle Database performs a fast refresh of the materialized view every 7 days, beginning 7 days after the materialized view is created.

Because the materialized view conforms to the conditions for fast refresh, the database will perform a fast refresh. The preceding statement also establishes storage characteristics that the database uses to maintain the materialized view.

### Automatic Refresh Times for Materialized Views: Example

The following statement creates the complex materialized view `all_customers` that queries the employee tables on the remote and local databases:

```
CREATE MATERIALIZED VIEW all_customers
  PCTFREE 5 PCTUSED 60
  TABLESPACE example
  STORAGE (INITIAL 50K)
  USING INDEX STORAGE (INITIAL 25K)
  REFRESH START WITH ROUND(SYSDATE + 1) + 11/24
  NEXT NEXT_DAY(TRUNC(SYSDATE), 'MONDAY') + 15/24
  AS SELECT * FROM sh.customers@remote
    UNION
    SELECT * FROM sh.customers@local;
```

Oracle Database automatically refreshes this materialized view tomorrow at 11:00 a.m. and subsequently every Monday at 3:00 p.m. The default refresh method is `FORCE`. The defining query contains a `UNION` operator, which is not supported for fast refresh, so the database will automatically perform a complete refresh.

The preceding statement also establishes storage characteristics for both the materialized view and the index that the database uses to maintain it:

- The first `STORAGE` clause establishes the sizes of the first and second extents of the materialized view as 50 kilobytes each.
- The second `STORAGE` clause, appearing with the `USING INDEX` clause, establishes the sizes of the first and second extents of the index as 25 kilobytes each.

### Creating a Fast Refreshable Materialized View: Example

The following statement creates a fast-refreshable materialized view that selects columns from the `order_items` table in the sample `oe` schema, using the `UNION` set operator to restrict the rows returned from the `product_information` and `inventories` tables using `WHERE` conditions. The materialized view logs for `order_items` and `product_information` were created in the "Examples" section of `CREATE MATERIALIZED VIEW LOG`. This example also requires a materialized view log on `oe.inventories`.

```
CREATE MATERIALIZED VIEW LOG ON inventories
  WITH (quantity_on_hand);

CREATE MATERIALIZED VIEW warranty_orders REFRESH FAST AS
  SELECT order_id, line_item_id, product_id FROM order_items o
  WHERE EXISTS
    (SELECT * FROM inventories i WHERE o.product_id = i.product_id
     AND i.quantity_on_hand IS NOT NULL)
  UNION
  SELECT order_id, line_item_id, product_id FROM order_items
  WHERE quantity > 5;
```

The materialized view `warranty_orders` requires that materialized view logs be defined on `order_items` (with `product_id` as a join column) and on `inventories` (with `quantity_on_hand` as a filter column). See "Specifying Filter Columns for Materialized

[View Logs: Example](#) and ["Specifying Join Columns for Materialized View Logs: Example"](#).

### Creating a Nested Materialized View: Example

The following example uses the materialized view from the preceding example as a master table to create a materialized view tailored for a particular sales representative in the sample oe schema:

```
CREATE MATERIALIZED VIEW my_warranty_orders
  AS SELECT w.order_id, w.line_item_id, o.order_date
  FROM warranty_orders w, orders o
 WHERE o.order_id = w.order_id
   AND o.sales_rep_id = 165;
```

### Specify Annotations at the View Level

The following example adds annotations Title value Tab1 MV1 and Snapshot without a value to the materialized view MView1:

```
CREATE MATERIALIZED VIEW MView1 ANNOTATIONS (Title 'Tab1 MV1', ADD Snapshot) AS SELECT
* from Table1;
```

### Specify Annotations at the View and Column Level

The following example adds Hidden to column T, Title with value Tab1 MV1, and Snapshot without a value to the materialized view MView1 :

```
CREATE MATERIALIZED VIEW MView1(T ANNOTATIONS (Hidden)) ANNOTATIONS (Title 'Tab1 MV1',
ADD Snapshot)
  AS SELECT * from Table1;
```

## CREATE MATERIALIZED VIEW LOG

### Purpose

Use the CREATE MATERIALIZED VIEW LOG statement to create a **materialized view log**, which is a table associated with the master table of a materialized view.

#### Note:

The keyword SNAPSHOT is supported in place of MATERIALIZED VIEW for backward compatibility.

Materialized view logs are used for two types of materialized view refreshes: fast refresh and synchronous refresh.

**Fast refresh** uses a conventional materialized view log. During a fast refresh (also called an incremental refresh), when DML changes are made to master table data, Oracle Database stores rows describing those changes in the materialized view log and then uses the materialized view log to refresh materialized views based on the master table.

**Synchronous refresh** uses a special type of materialized view log called a **staging log**. During a synchronous refresh, DML changes are first described in the staging log and then applied to the master tables and the materialized views simultaneously. This guarantees that

the master table data and materialized view data are in sync throughout the refresh process. This refresh method is useful in data warehousing environments.

Without a materialized view log, Oracle Database must reexecute the materialized view query to refresh the materialized view. This process is called a **complete refresh**. Usually, a complete refresh takes more time to complete than a fast refresh or a synchronous refresh.

A materialized view log is located in the master database in the same schema as the master table. A master table can have only one materialized view log defined on it.

To fast refresh or synchronous refresh a materialized join view, you must create a materialized view log for each of the tables referenced by the materialized view.

Fast refresh supports two types of materialized view logs: timestamp-based materialized view logs and commit SCN-based materialized view logs. Timestamp-based materialized view logs use timestamps and require some setup operations when preparing to refresh the materialized view. Commit SCN-based materialized view logs use commit SCN data rather than timestamps, which removes the need for the setup operations and thus can improve the speed of the materialized view refresh. If you specify the `COMMIT SCN` clause, then a commit SCN-based materialized view log is created. Otherwise, a time-stamp based materialized view log is created. Note that only new materialized view logs can take advantage of `COMMIT SCN`. Existing materialized view logs cannot be altered to add `COMMIT SCN` unless they are dropped and recreated. Refer to *Oracle Database Data Warehousing Guide* for more information.

Synchronous refresh supports only timestamp-based staging logs.

#### See Also:

- [CREATE MATERIALIZED VIEW](#), [ALTER MATERIALIZED VIEW](#), *Oracle Database Concepts*, *Oracle Database Data Warehousing Guide*, and *Oracle Database Administrator's Guide* for information on materialized views in general
- [ALTER MATERIALIZED VIEW LOG](#) for information on modifying a materialized view log
- [DROP MATERIALIZED VIEW LOG](#) for information on dropping a materialized view log
- *Oracle Database Utilities* for information on using direct loader logs

#### Prerequisites

The privileges required to create a materialized view log directly relate to the privileges necessary to create the underlying objects associated with a materialized view log.

- If you own the master table, then you can create an associated materialized view log if you have the `CREATE TABLE` privilege.
- If you are creating a materialized view log for a table in another user's schema, then you must have the `CREATE ANY TABLE` and `COMMENT ANY TABLE` system privileges, as well as either the `READ` or `SELECT` object privilege on the master table or the `READ ANY TABLE` or `SELECT ANY TABLE` system privilege.

In either case, the owner of the materialized view log must have sufficient quota in the tablespace intended to hold the materialized view log or must have the `UNLIMITED TABLESPACE` system privilege.

 **See Also:**

*Oracle Database Data Warehousing Guide* for more information about the prerequisites for creating a materialized view log

### Restrictions

The statement `CREATE MATERIALIZED VIEW LOG` does not support the following columns in the Master Table:

- Hidden columns
- Identity columns
- BFILE columns
- Temporal validity columns

## Syntax

`create_materialized_vw_log ::=`

(*physical\_attributes\_clause ::=, logging\_clause ::=, parallel\_clause ::=,  
table\_partitioning\_clauses ::= (in CREATE TABLE), new\_values\_clause ::=,  
mv\_log\_purge\_clause ::=, for\_refresh\_clause ::=.*)

`physical_attributes_clause ::=`

*(storage\_clause:=)*

*logging\_clause::=*

*parallel\_clause::=*

*new\_values\_clause::=*

*mv\_log\_purge\_clause::=*

*for\_refresh\_clause::=*

## Semantics

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the materialized view log does not exist, a new materialized view log is created at the end of the statement.
- If the materialized view log exists, this is the materialized view log you have at the end of the statement. A new one is not created because the older materialized view log is detected.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

### *schema*

Specify the schema containing the materialized view log master table. If you omit `schema`, then Oracle Database assumes the master table is contained in your own schema. Oracle Database creates the materialized view log in the schema of its master table. You cannot create a materialized view log for a table in the schema of the user `SYS`.

### *table*

Specify the name of the master table for which the materialized view log is to be created. Oracle Database encrypts any columns in the materialized view log that are encrypted in the master table, using the same encryption algorithm.

### Restrictions on Master Tables of Materialized View Logs

The following restrictions apply to master tables of materialized view logs:

- You cannot create a materialized view log for a temporary table or for a view.
- You cannot create a materialized view log for a master table with a virtual column.

#### See Also:

["Creating a Materialized View Log for Fast Refresh: Examples"](#)

## SHARING

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- `METADATA` - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- `NONE` - The object is not shared and can only be accessed in the application root.

***physical\_attributes\_clause***

Use the *physical\_attributes\_clause* to define physical and storage characteristics for the materialized view log.

 **See Also:**

[physical\\_attributes\\_clause](#) and [storage\\_clause](#) for a complete description these clauses, including default values

**TABLESPACE Clause**

Specify the tablespace in which the materialized view log is to be created. If you omit this clause, then the database creates the materialized view log in the default tablespace of the schema of the materialized view log.

***logging\_clause***

Specify either `LOGGING` or `NOLOGGING` to establish the logging characteristics for the materialized view log. The default is the logging characteristic of the tablespace in which the materialized view log resides.

 **See Also:**

[logging\\_clause](#) for a full description of this clause

**CACHE | NOCACHE**

For data that will be accessed frequently, `CACHE` specifies that the blocks retrieved for this log are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables.

`NOCACHE` specifies that the blocks are placed at the least recently used end of the LRU list. The default is `NOCACHE`.

 **Note:**

`NOCACHE` has no effect on materialized view logs for which you specify `KEEP` in the *storage\_clause*.

 **See Also:**

[CREATE TABLE](#) for information about specifying `CACHE` or `NOCACHE`

### ***parallel\_clause***

The *parallel\_clause* lets you indicate whether parallel operations will be supported for the materialized view log.

For complete information on this clause, refer to [parallel\\_clause](#) in the documentation on CREATE TABLE.

### ***table\_partitioning\_clauses***

Use the *table\_partitioning\_clauses* to indicate that the materialized view log is partitioned on specified ranges of values or on a hash function. Partitioning of materialized view logs is the same as partitioning of tables.

#### See Also:

[table\\_partitioning\\_clauses](#) in the CREATE TABLE documentation

### **WITH Clause**

Use the WITH clause to indicate whether the materialized view log should record the primary key, rowid, object ID, or a combination of these row identifiers when rows in the master are changed. You can also use this clause to add a sequence to the materialized view log to provide additional ordering information for its records.

This clause also specifies whether the materialized view log records additional columns that might be referenced as **filter columns**, which are non-primary-key columns referenced by subquery materialized views, or **join columns**, which are non-primary-key columns that define a join in the subquery WHERE clause.

If you omit this clause, or if you specify the clause without PRIMARY KEY, ROWID, or OBJECT ID, then the database stores primary key values by default. However, the database does not store primary key values implicitly if you specify only OBJECT ID or ROWID at create time. A primary key log, created either explicitly or by default, performs additional checking on the primary key constraint.

### **OBJECT ID**

Specify OBJECT ID to indicate that the system-generated or user-defined object identifier of every modified row should be recorded in the materialized view log.

#### **Restriction on OBJECT ID**

You can specify OBJECT ID only when creating a log on an object table, and you cannot specify it for storage tables.

### **PRIMARY KEY**

Specify PRIMARY KEY to indicate that the primary key of all rows changed should be recorded in the materialized view log.

### **ROWID**

Specify ROWID to indicate that the rowid of all rows changed should be recorded in the materialized view log.

## SEQUENCE

Specify SEQUENCE to indicate that a sequence value providing additional ordering information should be recorded in the materialized view log. Sequence numbers are necessary to support fast refresh after some update scenarios.

### See Also:

*Oracle Database Data Warehousing Guide* for more information on the use of sequence numbers in materialized view logs and for examples that use this clause

## COMMIT SCN

Without the COMMIT SCN clause, the materialized view log is based on timestamps and requires some setup operations when preparing to refresh the materialized view. Specify COMMIT SCN to instruct the database to use commit SCN data rather than timestamps. This setting removes the need for the setup operations and thus can improve the speed of the materialized view refresh.

You can create the following types of local materialized views (including both ON COMMIT and ON DEMAND) on master tables with commit SCN-based materialized view logs:

- Materialized aggregate views, including materialized aggregate views on a single table
- Materialized join views
- Primary-key-based and rowid-based single table materialized views
- UNION ALL materialized views, where each UNION ALL branch is one of the above materialized view types

You cannot create remote materialized views on master tables with commit SCN-based materialized view logs.

### Restrictions on COMMIT SCN

The following restrictions apply to COMMIT SCN:

- Use of COMMIT SCN on a table with one or more LOB columns is not supported and causes ORA-32421.
- Creating a materialized view on master tables with different types of materialized view logs (that is, a master table with timestamp-based materialized view logs and a master table with commit SCN-based materialized view logs) is not supported and causes ORA-32414.
- If you specify COMMIT SCN, then you cannot specify FOR SYNCHRONOUS REFRESH.

### *column*

Specify the columns whose values you want to be recorded in the materialized view log for all rows that are changed. Typically these columns are filter columns and join columns.

### Restrictions on the WITH Clause

This clause is subject to the following restrictions:

- You can specify only one PRIMARY KEY, one ROWID, one OBJECT ID, one SEQUENCE, and one column list for each materialized view log.

- Primary key columns are implicitly recorded in the materialized view log. Therefore, you cannot specify any of the following combinations if `column` contains one of the primary key columns:

```
WITH ... PRIMARY KEY ... (column)
WITH ... (column) ... PRIMARY KEY
WITH (column)
```

 **See Also:**

- [CREATE MATERIALIZED VIEW](#) for information on explicit and implicit inclusion of materialized view log values
- *Oracle Database Administrator's Guide* for more information about filter columns and join columns
- "[Specifying Filter Columns for Materialized View Logs: Example](#)" and "[Specifying Join Columns for Materialized View Logs: Example](#)"

### NEW VALUES Clause

The NEW VALUES clause lets you determine whether Oracle Database saves both old and new values for update DML operations in the materialized view log.

 **See Also:**

- "[Including New Values in Materialized View Logs: Example](#)"

### INCLUDING

Specify INCLUDING to save both new and old values in the log. If this log is for a table on which you have a single-table materialized aggregate view, and if you want the materialized view to be eligible for fast refresh, then you must specify INCLUDING.

### EXCLUDING

Specify EXCLUDING to disable the recording of new values in the log. This is the default. You can use this clause to avoid the overhead of recording new values. Do not use this clause if you have a fast-refreshable single-table materialized aggregate view defined on the master table.

#### ***mv\_log\_purge\_clause***

Use this clause to specify the purge time for the materialized view log.

- IMMEDIATE SYNCHRONOUS: the materialized view log is purged immediately after refresh. This is the default.
- IMMEDIATE ASYNCHRONOUS: the materialized view log is purged in a separate Oracle Scheduler job after the refresh operation.
- START WITH, NEXT, and REPEAT INTERVAL set up a scheduled purge that is independent of the materialized view refresh and is initiated during CREATE or

ALTER MATERIALIZED VIEW LOG statement. This is very similar to scheduled refresh syntax in a CREATE or ALTER MATERIALIZED VIEW statement:

- The START WITH datetime expression specifies when the purge starts.
- The NEXT datetime expression computes the next run time for the purge.

If you specify REPEAT INTERVAL, then the next run time will be: SYSDATE + *interval\_expr*.

A CREATE MATERIALIZED VIEW LOG statement with a scheduled purge creates an Oracle Scheduler job to perform log purge. The job calls the DBMS\_SNAPSHOT.PURGE\_LOG procedure to purge the materialized view logs. This process allows you to amortize the purging costs over several materialized view refreshes.

#### Restriction on *mv\_log\_purge\_clause*

This clause is not valid for materialized view logs on temporary tables.

#### See Also:

*Oracle Database Data Warehousing Guide* for more information on purging materialized view logs

#### *for\_refresh\_clause*

Use this clause to specify the refresh method for which the materialized view log will be used. You can specify only one refresh method for any given master table.

#### FOR SYNCHRONOUS REFRESH

Specify this clause to create a staging log that can be used for synchronous refresh. Use *staging\_log\_name* to specify the name of the staging log to be created. The staging log will be created in the schema in which the master table resides.

After you create the staging log, you cannot perform DML operations directly on the master table. You must use the procedures in the DBMS\_SYNC\_REFRESH package to prepare and execute change data operations.

#### Restrictions on Synchronous Refresh

The following restrictions apply to synchronous refresh:

- If you specify FOR SYNCHRONOUS REFRESH, then you cannot specify COMMIT SCN.
- To be eligible for synchronous refresh, the master table must satisfy the following criteria:
  - If the master table is a fact table, then it must be partitioned.
  - The master table must have a key. If the master table is a dimension table, then it must have a primary key defined on it. If the master table is a fact table, then the set of columns that are the foreign keys of the dimension tables joined to the fact table are deemed to be the key.
  - The master table cannot have a non-NULL Virtual Private Database (VPD) policy or a trigger defined on it.

Oracle Database may allow you to create a staging log on a master table even if all of the preceding criteria are not met. However, the master table will not be eligible for synchronous refresh.

- Any existing materialized views on the master table must be refresh-on-demand materialized views. If an existing materialized view is a refresh-on-commit materialized view, then you must change it to a refresh-on-demand materialized view with the `alter_mv_refresh` clause of ALTER MATERIALIZED VIEW before you create the staging log.

 **See Also:**

- Oracle Database Data Warehousing Guide* for the complete steps for using synchronous refresh
- Oracle Database PL/SQL Packages and Types Reference* for information on the `DBMS_SYNC_REFRESH` package

## FOR FAST REFRESH

Specify this clause to create a materialized view log that can be used for fast refresh. The materialized view log will be created in the same schema in which the master table resides. This is the default.

### Examples

#### Creating a Materialized View Log for Fast Refresh: Examples

The following statement creates a materialized view log on the `oe.customers` table that specifies physical and storage characteristics:

```
CREATE MATERIALIZED VIEW LOG ON customers
  PCTFREE 5
  TABLESPACE example
  STORAGE (INITIAL 10K);
```

The materialized view log on `customers` supports fast refresh for primary key materialized views only.

The following statement creates another version of the materialized view log with the `ROWID` clause, which enables fast refresh for more types of materialized views:

```
CREATE MATERIALIZED VIEW LOG ON customers WITH PRIMARY KEY, ROWID;
```

This materialized view log on `customers` makes fast refresh possible for `rowid` materialized views and for materialized join views. To provide for fast refresh of materialized aggregate views, you must also specify the `SEQUENCE` and `INCLUDING NEW VALUES` clauses, as shown in the example that follows.

#### Specify a Purge Repeat Interval for a Materialized View Log: Example

The following statement creates a materialized view log on the `oe.orders` table. The contents of the log will be purged once every five days, beginning five days after the creation date of the materialized view log:

```
CREATE MATERIALIZED VIEW LOG ON orders
  PCTFREE 5
  TABLESPACE example
  STORAGE (INITIAL 10K)
  PURGE REPEAT INTERVAL '5' DAY;
```

## Specifying Filter Columns for Materialized View Logs: Example

The following statement creates a materialized view log on the `sh.sales` table and is used in "[Creating Materialized Aggregate Views: Example](#)". It specifies as filter columns all of the columns of the table referenced in that materialized view.

```
CREATE MATERIALIZED VIEW LOG ON sales
  WITH ROWID, SEQUENCE(amount_sold, time_id, prod_id)
  INCLUDING NEW VALUES;
```

## Specifying Join Columns for Materialized View Logs: Example

The following statement creates a materialized view log on the `order_items` table of the sample `oe` schema. The log records primary keys and `product_id`, which is used as a join column in "[Creating a Fast Refreshable Materialized View: Example](#)".

```
CREATE MATERIALIZED VIEW LOG ON order_items WITH (product_id);
```

## Including New Values in Materialized View Logs: Example

The following example creates a materialized view log on the `oe.product_information` table that specifies `INCLUDING NEW VALUES`:

```
CREATE MATERIALIZED VIEW LOG ON product_information
  WITH ROWID, SEQUENCE (list_price, min_price, category_id), PRIMARY KEY
  INCLUDING NEW VALUES;
```

You could create the following materialized aggregate view to use the `product_information` log:

```
CREATE MATERIALIZED VIEW products_mv
  REFRESH FAST ON COMMIT
  AS SELECT SUM(list_price - min_price), category_id
    FROM product_information
   GROUP BY category_id;
```

This materialized view is eligible for fast refresh because the log defined on its master table includes both old and new values.

## Creating a Staging Log for Synchronous Refresh: Example

The following statement creates a staging log on the `sh.sales` fact table. The staging log is named `mystage_log` and is stored in the `sh` schema. It can be used for synchronous refresh.

```
CREATE MATERIALIZED VIEW LOG ON sales
  PCTFREE 5
  TABLESPACE example
  STORAGE (INITIAL 10K)
  FOR SYNCHRONOUS REFRESH USING mystage_log;
```

# CREATE MATERIALIZED ZONEMAP

## Purpose

Use the `CREATE MATERIALIZED ZONEMAP` statement to create a zone map.

A **zone map** is a special type of materialized view that stores information about zones. A **zone** is a set of contiguous data blocks on disk that stores the values of one or more table

columns. Multiple zones are usually required to store all of the values of the table columns. A zone map tracks the minimum and maximum table column values stored in each zone.

Zone maps enable you to reduce the I/O and CPU costs of table scans. When a SQL statement contains predicates on columns in a zone map, the database compares the predicate values to the minimum and maximum table column values stored in each zone to determine which zones to read during SQL execution.

Oracle Database supports the following types of zone maps:

- A **basic zone map** is defined on a single table and maintains zone information for specified columns in that table.

You can create a basic zone map either by specifying the `create_zonemap_on_table` clause, or by specifying the `create_zonemap_as_subquery` clause where the `FROM` clause of the defining subquery specifies a single table.

- A **join zone map** is defined on two or more joined tables and maintains zone information for specified columns in any of the joined tables.

You can create a join zone map by specifying the `create_zonemap_as_subquery` clause. The `FROM` clause of the defining subquery must specify a table that is left outer joined with one or more other tables.

Zone maps are commonly used with star schemas in data warehousing environments. However, a star schema is not a requirement for creating a zone map. In either case, this reference uses star schema terminology to refer to the tables in a zone map. In a join zone map, the outer table of the join(s) is referred to as the **fact table**, and the tables with which this table is joined are referred to as **dimension tables**. Collectively these tables are called the **base tables** of the zone map. In a basic zone map, the single table on which the zone map is defined is referred to as both the fact table and the base table of the zone map.

A base table of a zone map can be a partitioned or composite-partitioned table. In this case, the zone map maintains minimum and maximum column values for each partition (and subpartition) as well as for each zone.

You can create zone maps for use with or without attribute clustering:

- To create a zone map for use with attribute clustering, use either of the following methods:
  - Use the `CREATE MATERIALIZED ZONEMAP` statement and include attribute clustered columns in the zone map. Refer to the `attribute_clustering_clause` of `CREATE TABLE` and the `attribute_clustering_clause` clause of `ALTER TABLE` for more information.
  - Specify the `WITH MATERIALIZED ZONEMAP` clause while creating or modifying an attribute clustered table. Refer to the `zonemap_clause` of `CREATE TABLE` and the `MODIFY CLUSTERING` clause of `ALTER TABLE` for more information.
- To create a zone map for use without attribute clustering, use the `CREATE MATERIALIZED ZONEMAP` statement and include columns that are not attribute clustered in the zone map.

 See Also:

*Oracle Database Data Warehousing Guide* for more information on zone maps

## Prerequisites

To create a zone map **in your own schema**:

- You must have the `CREATE MATERIALIZED VIEW` system privilege and either the `CREATE TABLE` or `CREATE ANY TABLE` system privilege.
- You must have access to any base tables of the zone map that you do not own, either through a `READ` or `SELECT` object privilege on each of the tables or through the `READ ANY TABLE` or `SELECT ANY TABLE` system privilege.

To create a zone map **in another user's schema**:

- You must have the `CREATE ANY MATERIALIZED VIEW` system privilege.
- The owner of the zone map must have the `CREATE TABLE` system privilege. The owner must also have access to any base tables of the zone map that the schema owner does not own, either through a `READ` or `SELECT` object privilege on each of the tables or through the `READ ANY TABLE` or `SELECT ANY TABLE` system privilege.

To create a refresh-on-commit zone map (`REFRESH ON COMMIT` clause), in addition to the preceding privileges, you must have the `ON COMMIT REFRESH` object privilege on any base tables that you do not own or you must have the `ON COMMIT REFRESH` system privilege. Unlike materialized views, you can create a refresh-on-commit zone map even if there are no materialized view logs on the base tables.

When you create a zone map, Oracle Database creates one internal table and at least one index, all in the schema of the zone map. Oracle Database uses these objects to maintain the zone map data. You must have the privileges necessary to create these objects, and you must have sufficient quota in the target tablespace to store these objects or you must have the `UNLIMITED TABLESPACE` system privilege.

## Syntax

`create_materialized_zonemap ::=`

***create\_zonemap\_on\_table::=***

***create\_zonemap\_as\_subquery::=***

## ***zonemap\_attributes*::=**

**zonemap\_refresh\_clause::=**

 **Note:**

When specifying the `zonemap_refresh_clause`, you must specify at least one clause after the `REFRESH` keyword.

**Semantics****IF NOT EXISTS**

Specifying `IF NOT EXISTS` has the following effects:

- If the materialized zonemap does not exist, a new materialized zonemap is created at the end of the statement.
- If the materialized zonemap exists, this is the materialized zonemap you have at the end of the statement. A new one is not created because the older materialized zonemap is detected.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

**`create_zonemap_on_table`**

Use this clause to create a basic zone map.

**ON Clause**

In the `ON` clause, first specify the fact table for the zone map, and then inside the parentheses specify one or more columns of the fact table to be included in the zone map.

For each specified fact table `column`, Oracle creates two columns in the zone map. These two columns contain the minimum and maximum values of the fact table `column` in each zone. Oracle generates names for the zone map columns of the form `MIN_1_column` and `MAX_1_column` for the first specified fact table `column`, `MIN_2_column` and `MAX_2_column` for the second specified fact table `column`, and so on.

If you omit `schema`, then Oracle assumes the fact table is in your own schema. The fact table can be a table or a materialized view.

**`create_zonemap_as_subquery`**

Use this clause to create a basic zone map or a join zone map. To create a basic zone map, specify a single base table in the `FROM` clause of the defining subquery. To create a join zone map, specify a table that is left outer joined to one or more other tables in the `FROM` clause of the defining subquery.

**`column_alias`**

You can specify a column alias for each table column to be included in the zone map. The column alias list explicitly resolves any column name conflict, eliminating the need to specify aliases in the `SELECT` list of the defining subquery. If you specify any column alias in this clause, then you must specify an alias for each column in the `SELECT` list of the defining subquery. The first column alias you specify must be `ZONE_ID$`, which corresponds to the first column in the `SELECT` list, the `SYS_OP_ZONE_ID` function expression.

**`AS query_block`**

Specify the defining subquery of the zone map. The subquery must consist of a single *query\_block*. You can specify only the SELECT, FROM, WHERE, and GROUP BY clauses of *query\_block*, and those clauses must satisfy the following requirements:

- The first column in the SELECT list must be the SYS\_OP\_ZONE\_ID function expression. Refer to [SYS\\_OP\\_ZONE\\_ID](#) for more information.
- The remaining columns in the SELECT list must be function expressions that return minimum and maximum values for the columns you want to include in the zone map. For each column, specify a pair of function expressions of the following form:

`MIN([table.]column), MAX([table.]column)`

For *table*, specify the name or table alias for the table that contains the column. The table can be a fact table or dimension table. For *column*, specify the name or column alias for the column.

- The FROM clause can specify a fact table alone, or a fact table and one or more dimension tables with each dimension table left outer joined to the fact table. You can specify LEFT [OUTER] JOIN syntax in the FROM clause, or apply the outer join operator (+) to dimension table columns in the join condition in the WHERE clause. You can optionally specify a table alias for any of the tables in the FROM clause. Fact tables and dimension tables can be tables or materialized views.
- In the WHERE clause, you can specify only left outer join conditions using the outer join operator(+).
- You must specify a GROUP BY clause with the same SYS\_OP\_ZONE\_ID function expression that you specified for the first column of the SELECT list.

### ***schema***

Specify the schema to contain the zone map. If you omit *schema*, then Oracle Database creates the zone map in your schema.

### ***zonemap\_name***

Specify the name of the zone map to be created. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)".

### ***zonemap\_attributes***

Use this clause to specify the following attributes for the zone map: TABLESPACE, SCALE, PCTFREE, PCTUSED, and CACHE or NOCACHE.

#### **TABLESPACE**

Specify the *tablespace* in which the zone map is to be created. If you omit this clause, then Oracle Database creates the zone map in the default tablespace of the schema containing the zone map.

#### **SCALE**

This clause lets you specify the zone map scale, which determines the number of contiguous disk blocks that form a zone. The scale is an integer value that represents a power of 2. For example, a scale of 10 means up to 2 raised to the 10th power, or 1024, contiguous disk blocks will form a zone. For *integer*, specify a value between 4 and 16, inclusive. The recommended value is 10; this is the default.

#### **PCTFREE**

Specify an *integer* representing the percentage of space in each data block of the zone map reserved for future updates to rows of the zone map. The integer value must be between 0 and 99, inclusive. The default value is 10. Refer to [physical\\_attributes\\_clause](#) for more information on the PCTFREE parameter.

### PCTUSED

Specify an *integer* representing the minimum percentage of used space that Oracle maintains for each data block of the zone map. The integer value must be between 0 and 99, inclusive. The default value is 40. Refer to [physical\\_attributes\\_clause](#) for more information on the PCTUSED parameter.

### CACHE | NOCACHE

For data that will be accessed frequently, CACHE specifies that the blocks retrieved for this zone map are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed.

NOCACHE specifies that the blocks are placed at the least recently used end of the LRU list. The default is NOCACHE.

### *zonemap\_refresh\_clause*

Use this clause to specify the default refresh method and mode for the zone map. If you do not specify a refresh method (FAST, COMPLETE, or FORCE), then FORCE is the default method. If you do not specify a refresh mode (ON clauses), then ON LOAD DATA MOVEMENT is the default mode.

#### FAST

Specify FAST to indicate the fast refresh method, which performs the refresh according to the changes that have occurred to the base tables. While zone maps are internally implemented as a type of materialized view, materialized view logs on base tables are not needed to perform a fast refresh of a zone map.

#### COMPLETE

Specify COMPLETE to indicate the complete refresh method, which is implemented by executing the defining query of the zone map. If you request a complete refresh, then Oracle Database performs a complete refresh even if a fast refresh is possible.

#### FORCE

Specify FORCE to indicate that when a refresh occurs, Oracle Database will perform a fast refresh if one is possible or a complete refresh if fast refresh is not possible. This is the default.

#### ON DEMAND

Specify ON DEMAND to indicate that database will not refresh the zone map unless you manually issue an ALTER MATERIALIZED ZONEMAP ... REBUILD statement. If you specify this clause, then the zone map is referred to as a refresh-on-demand zone map. Refer to [REBUILD](#) in the documentation on ALTER MATERIALIZED ZONEMAP for more information on rebuilding a zone map.

#### ON COMMIT

Specify ON COMMIT to indicate that a refresh is to occur whenever the database commits a transaction that operates on a base table of the zone map. If you specify this clause, then the

zone map is referred to as a refresh-on-commit zone map. This clause may increase the time taken to complete the commit, because the database performs the refresh operation as part of the commit process.

#### ON LOAD

Specify `ON LOAD` to indicate that a refresh is to occur at the end of a direct-path insert (serial or parallel) resulting either from an `INSERT` or a `MERGE` operation.

#### ON DATA MOVEMENT

Specify `ON DATA MOVEMENT` to indicate that a refresh is to occur at the end of the following data movement operations:

- Data redefinition using the `DBMS_REDEFINITION` package
- Table partition maintenance operations that are specified by the following clauses of `ALTER TABLE`: `coalesce_table`, `merge_table_partitions`, `move_table_partition`, and `split_table_partition`

#### ON LOAD DATA MOVEMENT

Specify `ON LOAD DATA MOVEMENT` to indicate that a refresh is to occur at the end of a direct-path insert or a data movement operation. This is the default.

#### ENABLE | DISABLE PRUNING

This clause lets you control the use of the zone map for pruning.

- Specify `ENABLE PRUNING` to enable use of the zone map for pruning. This is the default.
- Specify `DISABLE PRUNING` to disable use of the zone map for pruning. The optimizer will not use the zone map for pruning, but the database will continue to maintain the zone map.

If the setting is `ENABLE PRUNING`, then the optimizer will consider using the zone map for pruning during SQL operations that include any of the following conditions:

- Comparison conditions: `=`, `<=`, `<`, `>=`, `>`

The condition must be a simple comparison condition that has a column name on one side and a literal or bind variable on the other side. For example:

```
WHERE country_name = 'United States of America'  
WHERE country_name = :country1  
WHERE 10000 >= salary
```

- `IN` condition

The `IN` condition must have a column name on the left side and an expression list of literals or bind variables on the right side. For example:

```
WHERE country_name IN ('Germany', 'India', 'United Kingdom')  
WHERE country_name IN (:country1, :country2, :country3)  
WHERE prod_id IN (20, 48, 132, 143)
```

- `LIKE` condition

The `LIKE` condition must have a column name on the left side and a text literal on the right side. The text literal is the pattern for the `LIKE` condition and it must contain at least one pattern matching character. Valid pattern matching characters are the underscore (`_`), which matches exactly one character, and the percent sign

(%), which matches zero or more characters. The first character of the pattern cannot be a pattern matching character. For example:

```
WHERE prod_name LIKE 'DVD%'
WHERE prod_name LIKE 'Model%Cordless%Battery'
WHERE prod_name LIKE 'CD%Pack of _'
```

### See Also:

[Conditions](#) for more information on conditions

## Restrictions on Zone Maps

Zone maps are subject to the following restrictions:

- A table can be a fact table for at most one zone map. A table can be a dimension table for multiple zone maps. A table can be a fact table for one zone map and a dimension table for other zone maps.
- A base table of a zone map cannot be an external table, an index-organized table, a remote table, a temporary table, or a view.
- A base table of a zone map cannot be in the schema of the user `SYS`.
- A zone map cannot be partitioned.
- You can define a zone map on a column of any scalar data type other than `BFILE`, `BLOB`, `CLOB`, `LONG`, `LONG RAW`, or `NCLOB`.
- All joins specified in the defining subquery of a zone map must be left outer equijoins with the fact table on the left side.
- If the `FROM` clause of the defining subquery for a zone map references a materialized view, then you must refresh that materialized view before refreshing the zone map.
- You cannot perform DML operations directly on a zone map.
- Each column of the zone map must have one of the following declared collations: `BINARY` or `USING_NLS_COMP`.

## Examples

The following statement creates a basic zone map called `sales_zmap`. The zone map tracks columns `cust_id` and `prod_id` in the table `sales`.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
  ON sales(cust_id, prod_id);
```

The following statement creates a basic zone map called `sales_zmap` that is similar to the zone map created in the previous example. However, this statement uses a defining subquery to create the zone map.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
  AS SELECT SYS_OP_ZONE_ID(rowid),
            MIN(cust_id), MAX(cust_id),
            MIN(prod_id), MAX(prod_id)
   FROM sales
  GROUP BY SYS_OP_ZONE_ID(rowid);
```

The following statement creates a join zone map called `sales_zmap`. The fact table for the zone map is `sales` and the zone map has one dimension table: `customers`. The zone map tracks two columns in the dimension table: `cust_state_province` and `cust_city`.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
  AS SELECT SYS_OP_ZONE_ID(s.rowid),
            MIN(cust_state_province), MAX(cust_state_province),
            MIN(cust_city), MAX(cust_city)
        FROM sales s
      LEFT OUTER JOIN customers c ON s.cust_id = c.cust_id
    GROUP BY SYS_OP_ZONE_ID(s.rowid);
```

The following statement creates a join zone map called `sales_zmap`. The fact table for the zone map is `sales` and the zone map has two dimension tables: `products` and `customers`. The zone map tracks five columns in the dimension tables: `prod_category` and `prod_subcategory` in the `products` table, and `country_id`, `cust_state_province`, and `cust_city` in the `customers` table.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
  AS SELECT SYS_OP_ZONE_ID(s.rowid),
            MIN(prod_category), MAX(prod_category),
            MIN(prod_subcategory), MAX(prod_subcategory),
            MIN(country_id), MAX(country_id),
            MIN(cust_state_province), MAX(cust_state_province),
            MIN(cust_city), MAX(cust_city)
        FROM sales s
      LEFT OUTER JOIN products p ON s.prod_id = p.prod_id
      LEFT OUTER JOIN customers c ON s.cust_id = c.cust_id
    GROUP BY sys_op_zone_id(s.rowid);
```

The following statement creates a join zone map that is identical to the zone map created in the previous example. The only difference is that the previous example uses the `LEFT OUTER JOIN` syntax in the `FROM` clause and the following example uses the outer join operator (+) in the `WHERE` clause.

```
CREATE MATERIALIZED ZONEMAP sales_zmap
  AS SELECT SYS_OP_ZONE_ID(s.rowid),
            MIN(prod_category), MAX(prod_category),
            MIN(prod_subcategory), MAX(prod_subcategory),
            MIN(country_id), MAX(country_id),
            MIN(cust_state_province), MAX(cust_state_province),
            MIN(cust_city), MAX(cust_city)
        FROM sales s, products p, customers c
      WHERE s.prod_id = p.prod_id(+)
        AND s.cust_id = c.cust_id(+)
    GROUP BY sys_op_zone_id(s.rowid);
```

## CREATE MLE ENV

### Purpose

MLE Environments are first-class schema objects that can be managed on their own and reused across multiple execution contexts.

MLE uses execution contexts to execute MLE language code and MLE environments allow you configure properties for these execution contexts. You can set language

options to customize the runtime of the MLE language and you can enable specific MLE modules to be imported to an execution context and manage dependencies.

Use `CREATE MLE ENV` to create a new MLE environment in the database in one of three ways:

You can create an MLE environment in one of three ways :

- As a fresh empty environment.
- As an environment with a list of imports and a language option string.
- By cloning an existing environment. Cloning an environment creates an independent copy that is not affected by subsequent changes to the original environment.

MLE environments use the same namespace as tables and procedures.

### Prerequisites

Users must have the `CREATE MLE` privilege to create an environment in their own schema, and the `CREATE ANY MLE` privilege to create an environment in other schemas. The user creating the environment must either own the environment being cloned or should have the `EXECUTE` privilege on it.

### Syntax

### Semantics

#### OR REPLACE

Specify `OR REPLACE` to re-create the environment, if it already exists. You can use this clause to change the definition of an existing environment without dropping, re-creating, and regranting object privileges previously granted on it.

#### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the MLE environment does not exist, a new MLE environment is created at the end of the statement.
- If the MLE environment, this is the MLE environment you have at the end of the statement. A new one is not created because the older one is detected.

You can have one of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error:  
`ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

## Examples

The following example creates an empty MLE environment `myenv`.

```
CREATE MLE ENV scott."myenv";
```

The following example clones an existing MLE environment:

```
CREATE MLE ENV scott."myenv" CLONE "other_env";
```

 **See Also:**

- [MLE JavaScript Modules and Environments](#)
- [ALTER MLE ENV](#)
- [DROP MLE ENV](#)

# CREATE MLE MODULE

## Purpose

Multilingual Engine (MLE) allows developers to write, store, and execute JavaScript code in Oracle Database 23c on Linux x86-64 by using MLE Modules to encapsulate JavaScript.

Use `CREATE MLE MODULE` to create a new MLE module in the database.

 **See Also:**

[JavaScript Developer's Guide](#)

## Prerequisites

You must have the `CREATE MLE` privilege to create or replace an MLE module in your own schema, and the `CREATE ANY MLE` privilege to create or replace an MLE module in another user's schema.

## Syntax

## Semantics

### OR REPLACE

Specify `OR REPLACE` to re-create the module if it already exists. You can use this clause to change the definition of an existing module without dropping, re-creating, and regranting object privileges previously granted on it.

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the MLE module does not exist, a new MLE module is created at the end of the statement.
- If the MLE module exists, this is the MLE module you have at the end of the statement. A new one is not created because the older one is detected.

You can have one of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error:

`ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

### *schema*

Use `schema` to fully qualify the module name. If you do not specify `schema`, then the current schema is used.

The length of the module name must not exceed 128 bytes. MLE modules use the same namespace as tables and procedures.

### LANGUAGE, VERSION

Use `LANGUAGE` to specify the MLE language of the created module. You must use the value `JAVASCRIPT` when you create JavaScript modules. An `ORA-04101` error is thrown if an unsupported MLE language is used.

The optional `VERSION` clause specifies a version string for the MLE module. Version strings are purely informational and do not influence any behavior of MLE or the RDBMS. The version string must fit into a `VARCHAR2(256)`.

### CLOB, BLOB, BFILE

Use `USING` to create MLE modules from code contained in `CLOBS`, `BLOBS`, or `BFILES`.

You can specify the `BFILE` clause with a subquery or with a directory using `directory_object_name` and `server_file_name` to specify the directory and filename of the MLE module you want to use. Note that you must create the directory object before this step using `CREATE DIRECTORY`.

The `CLOB | BLOB | BFILE` clause specifies a subquery whose result must be a single row and column of the specified type (`CLOB`, `BLOB`, or `BFILE`) that holds the contents of the MLE module to be deployed. The `CLOB` option is available only if the MLE module contains textual data. The textual data in MLE modules contained in `BLOBS` and `BFILES` is encoded in `UTF-8`.

### AS

Use `AS` to specify the contents of the MLE module as a sequence of characters inlined in the DDL statement. As with `CLOBS`, the `AS` clause is only available when the source of the MLE module contains textual data. Do not encapsulate the character sequence within quotes. The character sequence is delimited by the end of the DDL statement.

#### See Also:

- [JavaScript Developer's Guide](#)
- [DROP MLE MODULE](#)
- [ALTER MLE MODULE](#)
- [CREATE MLE ENV](#)

## CREATE OPERATOR

### Purpose

Use the `CREATE OPERATOR` statement to create a new operator and define its bindings.

Operators can be referenced by indextypes and by SQL queries and DML statements. The operators, in turn, reference functions, packages, types, and other user-defined objects.

#### See Also:

[Oracle Database Data Cartridge Developer's Guide](#) and [Oracle Database Concepts](#) for a discussion of these dependencies and of operators in general

## Prerequisites

To create an operator in your own schema, you must have the CREATE OPERATOR system privilege. To create an operator in another schema, you must have the CREATE ANY OPERATOR system privilege. In either case, you must also have the EXECUTE object privilege on the functions and operators referenced.

## Syntax

*create\_operator ::=*

*binding\_clause ::=*

*implementation\_clause ::=*

*context\_clause ::=*

### ***using\_function\_clause ::=***

### **Semantics**

#### **OR REPLACE**

Specify OR REPLACE to replace the definition of the operator schema object.

#### **Restriction on Replacing an Operator**

You can replace the definition only if the operator has no dependent objects, such as indextypes supporting the operator.

#### **IF NOT EXISTS**

Specifying IF NOT EXISTS has the following effects:

- If the operator does not exist, a new operator is created at the end of the statement.
- If the operator exists, this is the operator you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of OR REPLACE or IF NOT EXISTS in a statement at a time. Using both OR REPLACE with IF NOT EXISTS in the very same statement results in the following error: ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.

Using IF EXISTS with CREATE results in ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.

#### ***schema***

Specify the schema containing the operator. If you omit *schema*, then the database creates the operator in your own schema.

#### ***operator***

Specify the name of the operator to be created. The name must satisfy the requirements listed in "Database Object Naming Rules".

#### ***binding\_clause***

Use the *binding\_clause* to specify one or more parameter data types (*parameter\_type*) for binding the operator to a function. The signature of each binding—the sequence of the data types of the arguments to the corresponding function—must be unique according to the rules of overloading.

The *parameter\_type* can itself be an object type. If it is, then you can optionally qualify it with its schema.

#### **Restriction on Binding Operators**

You cannot specify a *parameter\_type* of REF, LONG, or LONG RAW.

 **See Also:**

*Oracle Database PL/SQL Language Reference* for more information about overloading

### **RETURN Clause**

Specify the return data type for the binding.

The *return\_type* can itself be an object type. If so, then you can optionally qualify it with its schema.

### **Restriction on Binding Return Data Type**

You cannot specify a *return\_type* of REF, LONG, or LONG RAW.

### **SHARING**

Use the sharing clause if you want to create the object in an application root in the context of an application maintenance. This type of object is called an application common object and it can be shared with the application PDBs that belong to the application root.

You can specify how the object is shared using one of the following sharing attributes:

- METADATA - A metadata link shares the metadata, but its data is unique to each container. This type of object is referred to as a metadata-linked application common object.
- NONE - The object is not shared and can only be accessed in the application root.

### ***implementation\_clause***

Use this clause to describe the implementation of the binding.

### **ANCILLARY TO Clause**

Use the ANCILLARY TO clause to indicate that the operator binding is ancillary to the specified primary operator binding (*primary\_operator*). If you specify this clause, then do not specify a previous binding with just one number parameter.

### ***context\_clause***

Use the *context\_clause* to describe the functional implementation of a binding that is not ancillary to a primary operator binding.

### **WITH INDEX CONTEXT, SCAN CONTEXT**

Use this clause to indicate that the functional evaluation of the operator uses the index and a scan context that is specified by the implementation type.

### **COMPUTE ANCILLARY DATA**

Specify COMPUTE ANCILLARY DATA to indicate that the operator binding computes ancillary data.

### **WITH COLUMN CONTEXT**

Specify `WITH COLUMN CONTEXT` to indicate that Oracle Database should pass the column information to the functional implementation for the operator.

If you specify this clause, then the signature of the function implemented must include one extra `ODCIFuncCallInfo` structure.

 **See Also:**

*Oracle Database Data Cartridge Developer's Guide* for instructions on using the `ODCIFuncCallInfo` routine

#### ***using\_function\_clause***

The `using_function_clause` lets you specify the function that provides the implementation for the binding. The `function_name` can be a standalone function, packaged function, type method, or a synonym for any of these.

If the function is subsequently dropped, then the database marks all dependent objects `INVALID`, including the operator. However, if you then subsequently issue an `ALTER OPERATOR ... DROP BINDING` statement to drop the binding, then subsequent queries and DML will revalidate the dependent objects.

#### **Examples**

##### **Creating User-Defined Operators: Example**

This example creates a very simple functional implementation of equality and then creates an operator that uses the function. For a more complete set of examples, see *Oracle Database Data Cartridge Developer's Guide*.

```
CREATE FUNCTION eq_f(a VARCHAR2, b VARCHAR2) RETURN NUMBER AS
BEGIN
    IF a = b THEN RETURN 1;
    ELSE RETURN 0;
    END IF;
END;
/

CREATE OPERATOR eq_op
    BINDING (VARCHAR2, VARCHAR2)
    RETURN NUMBER
    USING eq_f;
```

# CREATE OUTLINE

## Purpose

 **Note:**

Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. SQL plan management creates SQL plan baselines, which offer superior SQL performance stability compared with stored outlines.

You can migrate existing stored outlines to SQL plan baselines by using the `MIGRATE_STORED_OUTLINE` function of the `DBMS_SPM` package or Enterprise Manager Cloud Control. When the migration is complete, the stored outlines are marked as migrated and can be removed. You can drop all migrated stored outlines on your system by using the `DROP_MIGRATED_STORED_OUTLINE` function of the `DBMS_SPM` package.

See Also: *Oracle Database SQL Tuning Guide* for more information about SQL plan management and *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_SPM` package

Use the `CREATE OUTLINE` statement to create a **stored outline**, which is a set of attributes used by the optimizer to generate an execution plan. You can then instruct the optimizer to use a set of outlines to influence the generation of execution plans whenever a particular SQL statement is issued, regardless of changes in factors that can affect optimization. You can also modify an outline so that it takes into account changes in these factors.

 **Note:**

The SQL statement you want to affect must be an exact string match of the statement specified when creating the outline.

 **See Also:**

- *Oracle Database SQL Tuning Guide* for information on execution plans
- [ALTER OUTLINE](#) for information on modifying an outline
- [ALTER SESSION](#) and [ALTER SYSTEM](#) for information on the `USE_STORED_OUTLINES` and `USE_PRIVATE_OUTLINES` parameters

## Prerequisites

To create a public or private outline, you must have the `CREATE ANY OUTLINE` system privilege.

If you are creating a clone outline from a source outline, then you must also have the `SELECT_CATALOG_ROLE` role.

You can enable or disable the use of stored outlines dynamically for an individual session or for the system:

- Enable the `USE_STORED_OUTLINES` parameter to use public outlines.
- Enable the `USE_PRIVATE_OUTLINES` parameter to use private stored outlines.

## Syntax

`create_outline ::=`

### Note:

None of the clauses after `outline` are required. However, you must specify at least one clause after `outline`, and it must be either the `FROM` clause or the `ON` clause.

## Semantics

### OR REPLACE

Specify `OR REPLACE` to replace an existing outline with a new outline of the same name.

### PUBLIC | PRIVATE

Specify `PUBLIC` if you are creating an outline for use by `PUBLIC`. This is the default.

Specify `PRIVATE` to create an outline for private use by the current session only. The data of this outline is stored in the current schema.

### `outline`

Specify the unique name to be assigned to the stored outline. The name must satisfy the requirements listed in "Database Object Naming Rules". If you do not specify `outline`, then the database generates an outline name.

 **See Also:**

["Creating an Outline: Example"](#)

**FROM *source\_outline* Clause**

Use the `FROM` clause to create a new outline by copying an existing one. By default, Oracle Database looks for `source_category` in the public area. If you specify `PRIVATE`, then the database looks for the outline in the current schema.

**Restriction on Copying an Outline**

If you specify the `FROM` clause, then you cannot specify the `ON` clause.

 **See Also:**

["Creating a Private Clone Outline: Example"](#) and ["Publicizing a Private Outline to the Public Area: Example"](#)

**FOR CATEGORY Clause**

Specify an optional name used to group stored outlines. For example, you could specify a category of outlines for end-of-week use and another for end-of-quarter use. If you do not specify `category`, then the outline is stored in the `DEFAULT` category.

**ON Clause**

Specify the SQL statement for which the database will create an outline when the statement is compiled. This clause is optional only if you are creating a copy of an existing outline using the `FROM` clause.

You can specify any one of the following statements: `SELECT`, `DELETE`, `UPDATE`, `INSERT ... SELECT`, `CREATE TABLE ... AS SELECT`.

**Restrictions on the ON Clause**

This clause is subject to the following restrictions:

- If you specify the `ON` clause, then you cannot specify the `FROM` clause.
- You cannot create an outline on a multitable `INSERT` statement.
- The SQL statement in the `ON` clause cannot include any DML operation on a remote object.

 **Note:**

In subsequent statements, you can specify additional outlines for the same SQL statement, but each outline for the same statement must specify a different category in the `CATEGORY` clause.

## Examples

### Creating an Outline: Example

The following statement creates a stored outline by compiling the `ON` statement. The outline is called `salaries` and is stored in the category `special`.

```
CREATE OUTLINE salaries FOR CATEGORY special
    ON SELECT last_name, salary FROM employees;
```

When this same `SELECT` statement is subsequently compiled, if the `USE_STORED_OUTLINES` parameter is set to `special`, the database generates the same execution plan as was generated when the outline `salaries` was created.

### Creating a Private Clone Outline: Example

The following statement creates a stored private outline `my_salaries` based on the public category `salaries` created in the preceding example.

```
CREATE OR REPLACE PRIVATE OUTLINE my_salaries
    FROM salaries;
```

### Publicizing a Private Outline to the Public Area: Example

The following statement copies back (publicizes) a private outline to the public area after private editing:

```
CREATE OR REPLACE OUTLINE public_salaries
    FROM PRIVATE my_salaries;
```

# CREATE PACKAGE

### Purpose

Packages are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `CREATE PACKAGE` statement to create the specification for a stored **package**, which is an encapsulated collection of related procedures, functions, and other program objects stored together in the database. The **package specification** declares these objects. The **package body**, specified subsequently, defines these objects.

**See Also:**

- [CREATE PACKAGE BODY](#) for information on specifying the implementation of the package
- [CREATE FUNCTION](#) and [CREATE PROCEDURE](#) for information on creating standalone functions and procedures
- [ALTER PACKAGE](#) and [DROP PACKAGE](#) for information on modifying and dropping a package
- *Oracle Database Development Guide* and *Oracle Database PL/SQL Packages and Types Reference* for detailed discussions of packages and how to use them

**Prerequisites**

To create or replace a package in your own schema, you must have the `CREATE PROCEDURE` system privilege. To create or replace a package in another user's schema, you must have the `CREATE ANY PROCEDURE` system privilege.

To embed a `CREATE PACKAGE` statement inside an Oracle Database precompiler program, you must terminate the statement with the keyword `END-EXEC` followed by the embedded SQL statement terminator for the specific language.

**See Also:**

*Oracle Database PL/SQL Language Reference* for more information

**Syntax**

Packages are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

**`create_package ::=`**

(`plsql_package_source`: See *Oracle Database PL/SQL Language Reference*.)

**Semantics****OR REPLACE**

Specify `OR REPLACE` to re-create the package specification if it already exists. Use this clause to change the specification of an existing package without dropping, re-creating, and

regranting object privileges previously granted on the package. If you change a package specification, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined package can still access the package without being regranted the privileges.

If any function-based indexes depend on the package, then the database marks the indexes DISABLED.

 **See Also:**

`ALTER PACKAGE` for information on recompiling package specifications

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the package does not exist, a new package is created at the end of the statement.
- If the package exists, this is the package you have at the end of the statement. A new one is not created because the older one is detected.

You can have `one of OR REPLACE or IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

### [ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the package is an editioned or noneditioned object if editioning is enabled for the schema object type `PACKAGE` in `schema`. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

### `plsql_package_source`

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the `plsql_package_source`, including examples.

## CREATE PACKAGE BODY

### Purpose

Package bodies are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `CREATE PACKAGE BODY` statement to create the body of a stored **package**, which is an encapsulated collection of related procedures, stored functions, and other program objects stored together in the database. The **package body** defines these

objects. The **package specification**, defined in an earlier CREATE PACKAGE statement, declares these objects.

Packages are an alternative to creating procedures and functions as standalone schema objects.

#### See Also:

- [CREATE FUNCTION](#) and [CREATE PROCEDURE](#) for information on creating standalone functions and procedures
- [CREATE PACKAGE](#) for a discussion of packages, including how to create packages
- [ALTER PACKAGE](#) for information on modifying a package
- [DROP PACKAGE](#) for information on removing a package from the database

#### Prerequisites

To create or replace a package in your own schema, you must have the CREATE PROCEDURE system privilege. To create or replace a package in another user's schema, you must have the CREATE ANY PROCEDURE system privilege. In both cases, the package body must be created in the same schema as the package.

To embed a CREATE PACKAGE BODY statement inside an Oracle Database precompiler program, you must terminate the statement with the keyword END-EXEC followed by the embedded SQL statement terminator for the specific language.

#### See Also:

*Oracle Database PL/SQL Language Reference*

#### Syntax

Package bodies are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

***create\_package\_body ::=***

(*plsql\_package\_body\_source*: See *Oracle Database PL/SQL Language Reference*.)

## Semantics

### OR REPLACE

Specify `OR REPLACE` to re-create the package body if it already exists. Use this clause to change the body of an existing package without dropping, re-creating, and regranting object privileges previously granted on it. If you change a package body, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined package can still access the package without being regranted the privileges.

 **See Also:**

[ALTER PACKAGE](#) for information on recompiling package bodies

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the package body does not exist, a new package body is created at the end of the statement.
- If the package body exists, this is the package body you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

**[ EDITIONABLE | NONEDITIONABLE ]**

If you do not specify this clause, then the package body inherits `EDITIONABLE` or `NONEDITIONABLE` from the package specification. If you do specify this clause, then it must match that of the package specification.

***plsql\_package\_body\_source***

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the `plsql_package_body_source`.

# CREATE PFILE

## Purpose

Use the `CREATE PFILE` statement to export either a binary server parameter file or the current In-Memory parameter settings into a text initialization parameter file. Creating a text parameter file is a convenient way to get a listing of the current parameter settings

being used by the database, and it lets you edit the file easily in a text editor and then convert it back into a server parameter file using the `CREATE SPFILE` statement.

Upon successful execution of this statement, Oracle Database creates a text parameter file on the server. In an Oracle Real Application Clusters environment, it will contain all parameter settings of all instances. It will also contain any comments that appeared on the same line with a parameter setting in the server parameter file.

#### Note on Creating Text Parameter Files in a CDB

When you create a text parameter file in a multitenant container database (CDB), the current container can be the root or a PDB.

- If the current container is the root, then the database creates a text file that contains the parameter settings for the root.
- If the current container is a PDB, then the database creates a text file that contains the parameter settings for the PDB. In this case you must specify a `pfile_name`.

#### See Also:

- [CREATE SPFILE](#) for information on server parameter files
- *Oracle Database Administrator's Guide* for additional information on text initialization parameter files and binary server parameter files
- *Oracle Real Application Clusters Administration and Deployment Guide* for information on using server parameter files in an Oracle Real Application Clusters environment

### Prerequisites

You must have one of the following system privileges to execute this statement:

- SYSDBA
- SYSDG
- SYSOPER
- SYSBACKUP
- SYSASM
- SYSRAC

You can execute this statement either before or after instance startup.

### Restrictions

You cannot overwrite OS files as a SYSDG, SYSOPER, or SYSRAC user.

## Syntax

*create\_pfile ::=*

## Semantics

### *pfile\_name*

Specify the name of the text parameter file you want to create. If you do not specify *pfile\_name*, then Oracle Database uses the platform-specific default initialization parameter file name. *pfile\_name* can include a path prefix. If you do not specify such a path prefix, then the database adds the path prefix for the default storage location, which is platform dependent.

### *spfile\_name*

Specify the name of the binary server parameter from which you want to create a text file.

- If you specify *spfile\_name*, then the file must exist on the server. If the file does not reside in the default directory for server parameter files on your operating system, then you must specify the full path.
- If you do not specify *spfile\_name*, then the database uses the spfile that is currently associated with the instance, usually the one that was used at startup. If no spfile is associated with the instance, then the database looks for the platform-specific default server parameter file name. If that file does not exist, then the database returns an error.

### See Also:

Creating and Configuring an Oracle Database

## MEMORY

Specify **MEMORY** to create a pfile using the current system-wide parameter settings. In an Oracle RAC environment, the created file will contain the parameter settings from each instance.

## Examples

### Creating a Parameter File: Example

The following example creates a text parameter file `my_init.ora` from a binary server parameter file `s_params.ora`:

```
CREATE PFILE = 'my_init.ora' FROM SPFILE = 's_params.ora';
```

 **Note:**

Typically you will need to specify the full path and filename for parameter files on your operating system. Refer to your Oracle operating system documentation for path information and default parameter file names.

# CREATE PLUGGABLE DATABASE

## Purpose

Use the `CREATE PLUGGABLE DATABASE` statement to create a pluggable database (PDB).

This statement enables you to perform the following tasks:

- Create a PDB by using the seed as a template

Use the `create_pdb_from_seed` clause to create a PDB by using the seed in the multitenant container database (CDB) as a template. The files associated with the seed are copied to a new location and the copied files are then associated with the new PDB.

- Create a PDB by cloning an existing PDB

Use the `create_pdb_clone` clause to create a PDB by copying an existing PDB and then plugging the copy into the CDB. The files associated with the existing PDB are copied to a new location and the copied files are associated with the new PDB.

- Create a PDB by plugging an unplugged PDB into a CDB

Use the `create_pdb_from_xml` clause to plug an unplugged PDB into a CDB, using an XML metadata file.

- Create a proxy PDB by referencing another PDB. A proxy PDB provides fully functional access to the referenced PDB.

Use the `create_pdb_clone` clause and specify `AS PROXY FROM` to create a proxy PDB.

- Create an application container, application seed, or application PDB

Use the `create_pdb_from_seed`, `create_pdb_clone`, or `create_pdb_from_xml` clause. To create an application container, you must specify the `AS APPLICATION CONTAINER` clause. To create an application seed, you must specify the `AS SEED` clause.

 **Note:**

A multitenant container database is the only supported architecture in Oracle Database 21c and later releases. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

 **Note:**

When a new PDB is established in a CDB, it is possible that the name of a service offered by the new PDB will collide with an existing service name. The namespace in which a collision can occur is that of the listener that gives access to the CDB. Within that namespace, collisions are possible among the names of CDB's default services, PDB's default services, and user-defined services. For example, if two or more CDBs on the same computer system use the same listener, and the newly established PDB has the same service name as another PDB in these CDBs, then a collision occurs.

When you create a PDB, you can specify new names for any potential colliding service names. See the clause [service\\_name\\_convert](#). If you discover a service name collision after a PDB is created, you must not attempt to operate the PDB that causes a collision with an existing service name. If the colliding name is that of the PDB's default service, then you must rename the PDB. If the colliding name is that of a user-created service within the PDB, then you must drop that service and create one in its place, with a non-colliding name, that has the same purpose and properties.

 **See Also:**

- [Oracle Multitenant Administrator's Guide](#) for more information on multi-tenant architecture and concepts.
- [ALTER PLUGGABLE DATABASE](#) and [DROP PLUGGABLE DATABASE](#) for information on modifying and dropping PDBs

### Prerequisites

You must be connected to a CDB. The CDB must be open and in `READ WRITE` mode.

To create a PDB or an application container, the current container must be the root and you must have the `CREATE PLUGGABLE DATABASE` system privilege, granted commonly.

To create an application seed or an application PDB, the current container must be an application root, the application container must be open and in `READ WRITE` mode, and you must have the `CREATE PLUGGABLE DATABASE` system privilege, either granted commonly or granted locally in that application container.

To specify the `create_pdb_clone` clause:

- If `src_pdb_name` refers to a PDB in the same CDB, then you must have the `CREATE PLUGGABLE DATABASE` system privilege in the root of the CDB in which the new PDB will be created and in the PDB being cloned.
- If `src_pdb_name` refers to a PDB in a remote database, then you must have the `CREATE PLUGGABLE DATABASE` system privilege in the root of the CDB in which the new PDB will be created. In addition, the remote user must have the `CREATE PLUGGABLE DATABASE` system privilege in the PDB to which `src_pdb_name` refers.

See *Oracle Multitenant Administrator's Guide* for more information on the prerequisites to PDB creation.

## Semantics

### *pdb\_name*

Specify the name of the PDB to be created. The name must satisfy the requirements listed in "Database Object Naming Rules". The first character of a PDB name must be an alphabet character. The remaining characters can be alphanumeric or the underscore character (\_).

The PDB name must be unique in the CDB, and it must be unique within the scope of all the CDBs whose instances are reached through a specific listener.

### AS APPLICATION CONTAINER

Specify this clause to create an application container.

#### See Also:

Creating and Removing Application Containers and Seeds

### ***using\_snapshot\_clause***

Specify this clause to create a PDB from an existing PDB snapshot that can be identified by its name, SCN, or timestamp.

If you additionally specify SNAPSHOT COPY, then the new PDB will depend on the existence of the specified PDB snapshot. This will affect your ability to drop or purge the new PDB.

### **AS SEED**

Specify this clause to create an application seed. The database assigns the seed a name of the form *application\_container\_name\$SEED*.

An application container can have at most one application seed. The application seed is optional, but, if it exists, you can use it to create application PDBs quickly that match the requirements of the application container. An application seed enables instant provisioning of application PDBs that are created from it.

#### **See Also:**

[Creating and Removing Application Containers and Seeds](#)

### ***create\_pdb\_from\_seed***

This clause enables you to create a PDB by using the seed in the CDB as a template.

#### **See Also:**

[Creating a PDB from Scratch](#)

### **ADMIN USER**

Use this clause to create an administrative user who can be granted the privileges required to perform administrative tasks on the PDB. For *admin\_user\_name*, specify name of the user to be created. Use the IDENTIFIED BY clause to specify the password for *admin\_user\_name*. Oracle Database creates a local user in the PDB and grants the `PDB_DBA` local role to that user.

### ***pdb\_dba\_roles***

This clause lets you grant one or more roles to the `PDB_DBA` role. Use this clause to grant roles that have the privileges required by the administrative user of the PDB. For *role*, specify a predefined role. For a list of predefined roles, refer to *Oracle Database Security Guide*.

You can also use the `GRANT` statement to grant roles to the `PDB_DBA` role after the PDB has been created. Until you have granted the appropriate privileges to the `PDB_DBA` role, the `SYS` and `SYSTEM` users can perform administrative tasks on a PDB.

***parallel\_pdb\_creation\_clause***

This clause instructs the CDB to use parallel execution servers to copy the new PDB's data files to a new location. This may result in faster creation of the PDB.

**PARALLEL**

If you specify PARALLEL, then the CDB automatically chooses the number of parallel execution servers to use. This is the default if the COMPATIBLE initialization parameter is set to 12.2 or higher.

**PARALLEL integer**

Use integer to specify the number of parallel execution servers to use. The CDB can ignore this setting, depending on the current database load and the number of available parallel execution servers. If you specify a value of 0 or 1, then the CDB does not parallelize the creation of the PDB. This can result in a longer PDB creation time.

***default\_tablespace***

If you specify this clause, then Oracle Database creates a smallfile tablespace and sets it as the default permanent tablespace for the PDB. Oracle Database will assign the default tablespace to any non-SYSTEM user for whom a different permanent tablespace is not specified. The *default\_tablespace* clause has the same semantics that it has for the CREATE DATABASE statement. For full information, refer to *default\_tablespace* in the documentation on CREATE DATABASE.

***pdb\_storage\_clause***

Use this clause to specify storage limits for the PDB.

- Use MAXSIZE to limit the amount of storage that can be used by all tablespaces in the PDB to the value specified with *size\_clause*. This limit includes the size of data files and temporary files for tablespaces belonging to the PDB. Specify MAXSIZE UNLIMITED to enforce no limit.
- Use MAX\_AUDIT\_SIZE to limit the amount of storage that can be used by unified audit OS spillover (.bin format) files in the PDB to the value specified with *size\_clause*. Specify MAX\_AUDIT\_SIZE UNLIMITED to enforce no limit.
- Use MAX\_DIAG\_SIZE to limit the amount of storage for diagnostics (trace files and incident dumps) in the Automatic Diagnostic Repository (ADR) that can be used by the PDB to the value specified with *size\_clause*. Specify MAX\_DIAG\_SIZE UNLIMITED to enforce no limit.

If you omit this clause, or specify STORAGE UNLIMITED, then there are no storage limits for the PDB. This is equivalent to specifying STORAGE (MAXSIZE UNLIMITED MAX\_AUDIT\_SIZE UNLIMITED MAX\_DIAG\_SIZE UNLIMITED).

***file\_name\_convert***

Use this clause to determine how the database generates the names of files (such as data files and wallet files) for the PDB.

- For *filename\_pattern*, specify a string found in names of files associated with the seed (when creating a PDB by using the seed), associated with the source PDB (when cloning a PDB), or listed in the XML file (when plugging a PDB into a CDB).

- For *replacement\_filename\_pattern*, specify a replacement string.

Oracle Database will replace *filename\_pattern* with *replacement\_filename\_pattern* when generating the names of files associated with the new PDB.

File name patterns cannot match files or directories managed by Oracle Managed Files.

You can specify FILE\_NAME\_CONVERT = NONE, which is the same as omitting this clause. If you omit this clause, then the database first attempts to use Oracle Managed Files to generate file names. If you are not using Oracle Managed Files, then the database uses the PDB\_FILE\_NAME\_CONVERT initialization parameter to generate file names. If this parameter is not set, then an error occurs.

#### ***service\_name\_convert***

Use this clause to rename the user-defined services of the new PDB based on the service names of the source PDB. When the service name of a new PDB conflicts with an existing service name in the CDB, plug-in violations can result. This clause enables you to avoid these violations.

- For *service\_name*, specify the name of a service found in the PDB seed (when creating a PDB in an application container by using the application seed) or in the source PDB (when cloning a PDB or plugging a PDB into a CDB).
- For *replacement\_service\_name*, specify the replacement name for the service.

Oracle Database will use the replacement service name for the service in the PDB being created.

You can specify SERVICE\_NAME\_CONVERT = NONE, which is the same as omitting this clause.

#### ***Restrictions on service\_name\_convert***

The *service\_name\_convert* clause is subject to the following restrictions:

- You cannot change the name of the default service for a PDB. The default service has the same name as the PDB.
- You cannot specify this clause when you use the *create\_pdb\_from\_seed* clause to create a PDB from the CDB seed, because the CDB seed does not have user-defined services. You can, however, specify this clause when you use the *create\_pdb\_from\_seed* clause to create an application PDB from the application seed.

#### ***path\_prefix\_clause***

Use this clause to ensure that file paths for directory objects associated with the PDB are restricted to the specified directory or its subdirectories. This clause also ensures that the following files associated with the PDB are restricted to the specified directory: the Oracle XML repository for the PDB, files created with a CREATE PFILE statement, and the export directory for Oracle wallets. You cannot modify the setting of this clause after you create the PDB. This clause does not affect files created by Oracle Managed Files.

- For *path\_name*, specify the absolute path name of an operating system directory. The single quotation marks are required, with the result that the path name is case sensitive. Oracle Database uses *path\_name* as a prefix for all file paths associated with the PDB.

Be sure to specify *path\_name* so that the resulting path name will be properly formed when relative paths are appended to it. For example, on UNIX systems, be sure to end *path\_name* with a forward slash (/), such as:

```
PATH_PREFIX = '/disk1/oracle/dba/salespdb/'
```

- For *directory\_object\_name*, specify the name of a directory object that exists in the CDB root (*CDB\$ROOT*). The directory object points to the absolute path to be used for *PATH\_PREFIX*.
- If you specify *PATH\_PREFIX* = *NONE*, then the relative paths for directory objects associated with the PDB are treated as absolute paths and are not restricted to a particular directory.

Omitting the *path\_prefix\_clause* is equivalent to specifying *PATH\_PREFIX* = *NONE*.

After the *path\_prefix\_clause* is specified for a PDB, existing directory objects might not work as expected, since the *PATH\_PREFIX* string is always added as a prefix to all local directory objects in the PDB. The *path\_prefix\_clause* only applies to user-created directory objects. It does not apply to Oracle-supplied directory objects.

#### ***tempfile\_reuse\_clause***

When you create a PDB, Oracle Database associates temp files with the new PDB. Depending on how you create the PDB, the temp files may already exist and may have been previously used.

Specify *TEMPFILE REUSE* to instruct the database to format and reuse a temp file associated with the new PDB if it already exists. If you specify this clause and a temp file does not exist, then the database creates the temp file.

If you do not specify *TEMPFILE REUSE* and a temp file to be associated with the new PDB already exists, then the database returns an error and does not create the PDB.

#### ***user tablespaces clause***

This clause lets you specify the tablespaces to be made available in the new PDB. The *SYSTEM*, *SYSAUX*, and *TEMP* tablespaces are available in all PDBs and cannot be specified in this clause.

You can use this clause to separate the data for multiple schemas into different PDBs.

- Specify *tablespace* to make the tablespace available in the new PDB. You can specify more than one tablespace in a comma-separated list.
- Specify *ALL* to make all tablespaces available in the new PDB. This is the default.
- Specify *ALL EXCEPT* to make all tablespaces available in the new PDB, except the specified tablespaces.
- Specify *NONE* to make only the *SYSTEM*, *SYSAUX*, and *TEMP* tablespaces available in the new PDB.

When the compatibility level of the CDB is 12.2 or higher, the tablespaces that are excluded by this clause are created offline in the new PDB, and they have no data files associated with them. When the compatibility level of the CDB is lower than 12.2, the tablespaces that are excluded by this clause are offline in the new PDB, and all data files that belong to these tablespaces are unnamed and offline.

#### **{ SNAPSHOT COPY | NO DATA }**

These clauses apply only when cloning a PDB with the *create\_pdb\_clone* clause. By default, the database creates each tablespace to be made available in the new PDB according to the settings specified for cloning the PDB. These clauses allow you to override those settings as follows:

- SNAPSHOT COPY - Clone the tablespace using storage snapshots.
- NO DATA - Clone the data model definition of the tablespace, but not the tablespace's data.

### { COPY | MOVE | NOCOPY }

These clauses apply when you plug in a PDB with the `create_pdb_from_xml` clause. By default, the database creates each tablespace to be made available in the new PDB according to the settings specified for plugging in the PDB. These clauses allow you to override those settings as follows:

- COPY - Copy the tablespace files to the new location.
- MOVE - Move the tablespace files to the new location.
- NOCOPY - Do not copy or move the tablespace files to the new location.

### *standbys\_clause*

Use this clause to specify whether the new PDB is included in one or more standby CDBs. If you include a PDB in a standby CDB, then during standby recovery the standby CDB will search for the data files for the PDB. If the data files are not found, then standby recovery will stop and you must copy the data files to the correct location before you can restart recovery.

- Specify `cdb_name` to include the new PDB in the specified standby CDB. You can specify more than one standby CDB name in a comma-separated list.
- Specify `ALL` to include the new PDB in all standby CDBs. This is the default.
- Specify `ALL EXCEPT` to include the new PDB in all standby CDBs, except the specified standby CDBs.
- Specify `NONE` to exclude the new PDB from all standby CDBs. When a PDB is excluded from all standby CDBs, the PDB's data files are unnamed and marked offline on all of the standby CDBs. Standby recovery will not stop if the data files for the PDB are not found on the standby. If you instantiate a new standby CDB after the PDB is created, then you must explicitly disable the PDB for recovery on the new standby CDB.

You can enable a PDB on a standby CDB after it was excluded on that standby CDB by copying the data files to the correct location, bringing the PDB online, and marking it as enabled for recovery.

### *logging\_clause*

Use this clause to specify the default logging attribute for tablespaces created within the PDB. The logging attribute controls whether certain DML operations are logged in the redo log file (`LOGGING`) or not (`NOLOGGING`). The default is `LOGGING`.

When creating a tablespace, you can override the default logging attribute by specifying the *logging\_clause* of the `CREATE TABLESPACE` statement.

Refer to *logging\_clause* for a full description of this clause.

### *create\_file\_dest\_clause*

By default, a newly created PDB inherits its Oracle Managed Files settings from the root. If the root uses Oracle Managed Files, then the PDB also uses Oracle Managed Files. The PDB shares the same base file system directory for Oracle Managed Files with the root and has its own subdirectory named with the GUID of the PDB. If the root does not use Oracle Managed Files, then the PDB also does not use Oracle Managed Files.

This clause lets you override the default behavior. You can enable or disable Oracle Managed Files for the PDB and you specify a different base file system directory or Oracle ASM disk group for the PDB's files.

- Specify `NONE` to disable Oracle Managed Files for the PDB.
- Specify either `directory_path_name` or `diskgroup_name` to enable Oracle Managed Files for the PDB.

Specify `directory_path_name` to designate the base file system directory for the PDB's files. Specify the full path name of the operating system directory. The directory must exist and Oracle processes must have appropriate permissions on the directory. The single quotation marks are required, with the result that the path name is case sensitive.

Specify `diskgroup_name` to designate the default Oracle ASM disk group for the PDB's files.

If you specify a value other than `NONE`, then the database implicitly sets the `DB_CREATE_FILE_DEST` initialization parameter with `SCOPE=SPFILE` in the PDB.

### HOST and PORT

These clauses are useful only if you are creating a PDB that you plan to reference from a proxy PDB. This type of PDB is called a referenced PDB.

When creating a referenced PDB:

- If the name of the listener is different from the host name of the PDB, then you must specify the `HOST` clause. For `hostname`, specify the fully qualified domain name of the listener. Enclose `hostname` in single quotation marks. For example: '`myhost.example.com`'.

In an Oracle Real Application Clusters (Oracle RAC) environment, you can specify for `hostname` any of the hosts for the PDB.

- If the port number of the listener is not 1521, then you must specify the `PORT` clause. For `number`, specify the port number for the listener.

A proxy PDB uses a database link to establish communication with its referenced PDB. After communication is established, the proxy PDB communicates directly with the referenced PDB without using a database link. The host name and port number of the listener for the referenced PDB must be correct for the proxy PDB to function properly.

#### See Also:

The clause **AS PROXY FROM** of `create_pdb_clone` for information on creating a proxy PDB

### `create_pdb_clone`

This clause enables you to create a new PDB by cloning a source to a target PDB. The source can be a PDB in the local CDB, or a PDB in a remote CDB. The target PDB is the clone of the source.

If the source is a PDB in the local CDB, then the source PDB can be plugged in or unplugged. If the source is a PDB in a remote CDB, then the source PDB must be plugged in.

If the source is a PDB in a remote CDB, then the source and the CDB that contains the target PDB must meet the following requirements:

- They must have the same endian format.
- They must have compatible character sets and national character sets, which means:
  - Every character in the source character set is available in the local CDB character set.
  - Every character in the source character set has the same code point value in the local CDB character set.
- They must have the same set of database options installed.

Users in the PDB who used the default temporary tablespace of the source PDB use the default temporary tablespace of the new PDB. Users who used non-default temporary tablespaces in the PDB continue to use the same local temporary tablespaces in the new PDB.

You can clone a united PDB or an isolated PDB with the same command. The only difference is that the keystore password you must provide are for different keystores.

### Hot Clone a PDB: Example

```
CREATE PLUGGABLE DATABASE CDB1_PDB2_CLONE FROM CDB1_PDB2
KEYSTORE IDENTIFIED BY keystore_password
```

For a **united** PDB:

- `keystore_password` is the `ROOT` keystore password.
- The wallet must be open in `ROOT`.

For an **isolated** PDB:

- `keystore_password` is the **new** keystore password for the PDB `CDB1_PDB2_CLONE`.
- The wallet must be open in `CDB1_PDB2_CLONE`.

### Clone a PDB: Example

#### United PDB

```
CREATE PLUGGABLE DATABASE CDB1_PDB1_C AS CLONE USING '/tmp/cdb1_pdb3.pdb'
KEYSTORE IDENTIFIED BY keystore_password DECRYPT USING transport_secret
```

- The wallet must be open in `ROOT`, if TDE is in use.
- If there are TDE keys in the `.pdb` file, you must specify `KEYSTORE IDENTIFIED BY` and provide `transport_secret`.
- `keystore_password` is the `ROOT` keystore password.

#### Isolated PDB

```
CREATE PLUGGABLE DATABASE CDB1_PDB2_C AS CLONE USING '/tmp/cdb1_pdb2.pdb'
```

- You need not specify `KEYSTORE IDENTIFIED BY` or `transport_secret`. If specified, they are ignored.
- The wallet need not be open in `ROOT`.

 See Also:

Cloning a PDB

## FROM

Use this clause to specify the source PDB. The files associated with the source are copied to a new location and these copied files are then associated with the new PDB.

The source PDB cannot be closed. It can be open as follows:

- If the CDB that contains the source PDB (the source CDB) is in ARCHIVELOG mode and local undo mode, then the source PDB can be open in READ WRITE mode and fully functional during the cloning operation. This is called hot PDB cloning.
- If the source CDB is not in ARCHIVELOG mode, then the source PDB must be open READ ONLY.

Specify the source PDBs as follows:

- If the source is a PDB in the local CDB, then use *src\_pdb\_name* to specify the name of the source PDB. You cannot specify PDB\$SEED for *src\_pdb\_name*. Instead, use the [create\\_pdb\\_from\\_seed](#) clause to create a PDB by using the seed as a template.
- If the source is a PDB in a remote CDB, then use *src\_pdb\_name* to specify the name of the source PDB and *dblink* to specify the name of the database link to use to connect to the remote CDB.

## AS PROXY FROM

Use this clause to create a proxy PDB by referencing a different PDB, which is referred to as the referenced PDB. The referenced PDB can be in the same CDB as the proxy PDB or in a different CDB. A local proxy PDB is in the same CDB as its referenced PDB, and a remote proxy PDB is in a different CDB than its referenced PDB.

For *src\_pdb\_name@dblink*, specify the referenced PDB.

 See Also:

Creating a PDB as a Proxy PDB

## *default\_tablespace*

Use this clause to specify a permanent default tablespace for the PDB. Oracle Database will assign the default tablespace to any non-SYSTEM user for whom a different permanent tablespace is not specified. The tablespace must already exist in the source PDB. Because the tablespace already exists, you cannot specify the DATAFILE clause or the extent\_management\_clause when creating a PDB with the [create\\_pdb\\_clone](#) clause.

***pdb\_storage\_clause***

Use this clause to specify storage limits for the new PDB. Refer to [\*pdb\\_storage\\_clause\*](#) for the full semantics of this clause.

***file\_name\_convert***

Use this clause to determine how the database generates the names of files for the new PDB. Refer to [\*file\\_name\\_convert\*](#) for the full semantics of this clause.

***service\_name\_convert***

Use this clause to determine how the database renames services for the new PDB. Refer to [\*service\\_name\\_convert:=\*](#) for the full semantics of this clause.

***path\_prefix\_clause***

Use this clause to ensure that all directory object paths associated with the PDB are restricted to the specified directory or its subdirectories. Refer to [\*path\\_prefix\\_clause\*](#) for the full semantics of this clause.

***tempfile\_reuse\_clause***

Specify TEMPFILE REUSE to instruct the database to format and reuse a temp file associated with the new PDB if it already exists. Refer to [\*tempfile\\_reuse\\_clause\*](#) for the full semantics of this clause.

**SNAPSHOT COPY**

You can specify SNAPSHOT COPY only when cloning a PDB. The source PDB can be in the local CDB or a remote CDB. The SNAPSHOT COPY clause instructs the database to clone the source PDB using storage snapshots. This reduces the time required to create the clone because the database does not need to make a complete copy of the source data files.

When you use the SNAPSHOT COPY clause to create a clone of a source PDB and the CLONEDB initialization parameter is set to FALSE, the underlying file system for the source PDB's files must support storage snapshots. Such file systems include Oracle Advanced Cluster File System (Oracle ACFS) and Direct NFS Client storage.

When you use the SNAPSHOT COPY clause to create a clone of a source PDB and the CLONEDB initialization parameter is set to TRUE, the underlying file system for the source PDB's files can be any local file system, network file system (NFS), or clustered file system that has Direct NFS enabled. However, the source PDB must remain in open read-only mode as long as any clones exist.

Direct NFS Client enables an Oracle database to access network attached storage (NAS) devices directly, rather than using the operating system kernel NFS client. If the PDB files are stored on Direct NFS Client storage, then the following additional requirements must be met:

- The source PDB files must be located on an NFS volume.
- Storage credentials must be stored in a Transparent Data Encryption keystore.
- The storage user must have the privileges required to create and destroy snapshots on the volume that hosts the source PDB files.
- Credentials must be stored in the keystore using an ADMINISTER KEY MANAGEMENT ADD SECRET SQL statement.

When you use the `SNAPSHOT COPY` clause to create a clone of a source PDB, the following restrictions apply to the source PDB as long as any clones exist:

- It cannot be unplugged.
- It cannot be dropped.

PDB clones created using the `SNAPSHOT COPY` clause cannot be unplugged. They can only be dropped. Attempting to unplug a clone created using the `SNAPSHOT COPY` clause results in an error.

For a PDB created using the `SNAPSHOT COPY` clause in an Oracle Real Application Clusters (Oracle RAC) environment, each node that must access the PDB's files must be mounted. For Oracle RAC databases running on Linux or UNIX platforms, the underlying NFS volumes must be mounted. If the Oracle RAC database is running on a Windows platform and using Direct NFS for shared storage, then you must update the `orafstab` file on all nodes with the created volume `export` and `mount` entries.

Storage clones are named and tagged using the new PDB GUID. You can query the `CLONETAG` column of `DBA_PDB_HISTORY` view to view clone tags for storage clones.

#### ***keystore\_clause***

Specify this clause if the source database has encrypted data or a keystore set.

If you want to create the PDB by cloning another PDB, and if the source database has encrypted data or a TDE master encryption key that has been set, then you must provide the keystore password of the target keystore in `keystore_password`.

You can find if the source database has encrypted data by querying the `DBA_ENCRYPTED_COLUMNS` data dictionary view or the `V$ENCRYPTED_TABLESPACES` dynamic performance view.

You can use the `EXTERNAL STORE` clause instead of `keystore_password` to clone a PDB that is using a united keystore. Note that you must configure the TDE SEPS wallet first before you use this option.

You cannot use the `EXTERNAL STORE` clause for a PDB that is using an isolated keystore.

You can set the password to a maximum length of 1024 bytes.

#### ***pdb\_refresh\_mode\_clause***

The `REFRESH MODE` clause applies only when cloning a PDB. The source PDB must be in a remote CDB, that is, you must specify the source PDB using the `FROM src_pdb_name@dblink` clause.

This clause lets you specify the refresh mode of the PDB. You can use this clause to create a **refreshable PDB**. Changes in the source PDB can be propagated to the refreshable PDB, either manually or automatically. This operation is called a refresh. You can specify the following refresh modes:

- `MANUAL` - This mode allows you to refresh the refreshable PDB manually at any time by issuing an `ALTER PLUGGABLE DATABASE REFRESH` statement.
- `EVERY refresh_interval MINUTES or HOURS` – This mode instructs the database to refresh the refreshable PDB every `refresh_interval` of selected time units, minutes or hours. If you select `MINUTES`, the `refresh_interval` must be less than

3000. If you select HOURS, the refresh\_interval must be less than 2000. This mode also allows you to refresh the PDB manually at any time by issuing an ALTER PLUGGABLE DATABASE REFRESH statement.

- NONE - If you specify this mode, then the clone PDB is not a refreshable PDB. The database cannot refresh the PDB automatically and you cannot refresh the PDB manually. If you specify this mode, then you cannot later change the PDB into a refreshable PDB. This is the default.

A refreshable PDB can be opened only in READ ONLY mode. A refreshable PDB must be closed in order for a refresh to occur. If it is not closed when you attempt to perform a manual refresh, then an error will occur. If it is not closed when the database attempts an automatic refresh, then the refresh will be deferred until the next scheduled refresh.

#### See Also:

- ALTER PLUGGABLE DATABASE [REFRESH](#) for information on refreshing a PDB manually
- ALTER PLUGGABLE DATABASE [pdb\\_refresh\\_mode\\_clause](#) for information on changing the refresh mode of a PDB
- *Oracle Database Administrator's Guide* for more information on refreshable PDBs

## RELOCATE

Use this clause to relocate a PDB from one CDB to another. The database first clones the source PDB to the target PDB, and then removes the source PDB. The database also moves the files associated with the PDB to a new location. This operation is the fastest way to relocate a PDB with minimal down time. The down time for the PDB is approximately the time required to copy the PDB's files from their old location to their new location. The source PDB can be open in READ WRITE mode and fully functional during the relocation operation.

You can specify the availability level with the AVAILABILITY keyword. The default availability is NORMAL. If you specify AVAILABILITY MAX, then additional operations are performed to ensure a smooth migration of the workload in a persistent connection between source and target.

In the `create_pdb_clone` clause, you must use the `FROM src_pdb_name@dblink` syntax to identify the location of the source PDB. For `src_pdb_name`, specify the name of the source PDB. For `dblink`, specify a database link that indicates the location of the source PDB. The database link must have been created in the CDB to which the PDB will be relocated. It can connect either to the root of the remote CDB or to the remote PDB.

## KEEP SOURCE

Specify `KEEP SOURCE` if you want to keep the source PDB and preserve it in an unplugged state.

 See Also:

Relocating a PDB

## NO DATA

The `NO DATA` clause applies only when cloning a PDB. This clause specifies that the source PDB's data model definition is cloned, but not the PDB's data. The dictionary data in the source PDB is cloned, but all user-created table and index data from the source PDB is discarded.

### Restrictions on the NO DATA Clause

The following restrictions apply to the `NO DATA` clause:

- The source PDB should be open in read only mode when you use the `NO DATA` clause to clone a PDB.
- You cannot specify `NO DATA` if the source PDB contains clustered tables, Advanced Queuing (AQ) tables, index-organized tables, or tables that contain abstract data type columns.

## HOST and PORT

These clauses are useful only if you are creating a PDB that you plan to reference from a proxy PDB. This type of PDB is called a referenced PDB. Refer to [HOST and PORT](#) for the full semantics of these clauses.

### `create_pdb_from_xml`

This clause enables you to create a PDB by plugging an unplugged PDB (the source database) into a CDB (the target CDB). If the source database is an unplugged PDB, then it may have been unplugged from the target CDB or a different CDB.

The source database and the target CDB must meet the following requirements:

- They must have the same endian format.
- They must have compatible character sets and national character sets, which means:
  - Every character in the source database character set is available in the target CDB character set.
  - Every character in the source database character set has the same code point value in the target CDB character set.
- They must have the same set of database options installed.

 See Also:

- Plugging In an Unplugged PDB
- *Oracle Database PL/SQL Packages and Types Reference* for more information on the `DBMS_PDB` package

## AS CLONE

Specify this clause only if the target CDB already contains a PDB that was created using the same set of data files. The source files remain as an unplugged PDB and can be used again. Specifying `AS CLONE` also ensures that Oracle Database generates new identifiers, such as DBID and GUID, for the new PDB.

## USING

This clause lets you specify a file that contains information about the source database that your are plugging in. For `filename`, specify the full path name of the file. You can obtain this file in one of the following ways:

- If the source database is an unplugged PDB, then the file was created by the `pdb_unplug_clause` of `ALTER PLUGGABLE DATABASE` as follows:
  - If the filename ends with the extension `.xml`, then it is an XML file containing metadata about the PDB. In this case, you must ensure that the XML metadata file, as well as the PDB's data files, are in a location that is accessible to the CDB.
  - If the filename ends with the extension `.pdb`, then it is a PDB archive file. This is a compressed file that includes an XML file containing metadata about the PDB, as well as the PDB's data files. The PDB archive file must exist in a location that is accessible to the CDB. When you use a `.pdb` archive file, this file is extracted when you plug in the PDB, and the PDB's files are placed in the same directory as the `.pdb` archive file. Therefore, the `source_file_directory` clause is not required.
- If the source database is a non-CDB, then you must create the XML metadata file using the `DBMS_PDB` package, and ensure that the XML metadata file, as well as the source non-CDB's data files, are in a location that is accessible to the CDB.

### See Also:

- [`pdb\_unplug\_clause` of `ALTER PLUGGABLE DATABASE`](#)
- [`Oracle Database PL/SQL Packages and Types Reference` for more information on the `DBMS\_PDB` package](#)

## `source_file_name_convert`

Specify this clause only if the contents of the XML file do not accurately describe the locations of the source files. If the files that must be used to plug in the source database are no longer in the location specified in the XML file, then use this clause to map the specified file names to the actual file names.

- For `filename_pattern`, specify the string for the location of the files as specified in the XML file.
- For `replacement_filename_pattern`, specify the string for the actual location that contains the files that must be used to create the PDB.

Oracle Database will replace `filename_pattern` with `replacement_filename_pattern` when searching for the source database files.

File name patterns cannot match files or directories managed by Oracle Managed Files.

If the files that must be used to create the PDB exist in the location specified in the XML file, you can either omit this clause or specify `SOURCE_FILE_NAME_CONVERT=NONE`.

#### ***source\_file\_directory***

Specify this clause only if the contents of the XML file do not accurately describe the locations of the source files *and* the source files are all present in a single directory. This clause is convenient when you have a large number of data files and specifying a replacement file name pattern for each file using the `source_file_name_convert` clause is not feasible.

- For `directory_path_name`, specify the absolute path of the directory that contains the source files. The directory is scanned to find the appropriate files based on the unplugged PDB's XML file.

You can specify this clause for configurations that use Oracle Managed Files and for configurations that do not use Oracle Managed Files.

If the files that must be used to create the PDB exist in the location specified in the XML file, you can either omit this clause or specify `SOURCE_DIRECTORY=NONE`.

#### **COPY**

Specify `COPY` if you want the files listed in the XML file to be copied to the new location and used for the new PDB. This is the default. You can use the optional `file_name_convert` clause to use pattern replacement in the new file names. Refer to [file\\_name\\_convert](#) for the full semantics of this clause.

#### **MOVE**

Specify `MOVE` if you want the files listed in the XML file to be moved, rather than copied, to the new location and used for the new PDB. You can use the optional `file_name_convert` clause to use pattern replacement in the new file names. Refer to [file\\_name\\_convert](#) for the full semantics of this clause.

If the storage locations are different mounts, or if the storage locations do not support move at the OS or storage level, then the `MOVE` clause first copies the files then deletes the originals.

#### **NOCOPY**

Specify `NOCOPY` if you want the files for the PDB to remain in their current locations. Use this clause if there is no need to copy or move the files required to plug in the PDB.

#### ***service\_name\_convert***

Use this clause to determine how the database renames services for the new PDB. Refer to [service\\_name\\_convert:=](#) for the full semantics of this clause.

#### ***default\_tablespace***

Use this clause to specify a permanent default tablespace for the PDB. Oracle Database will assign the default tablespace to any non-SYSTEM user for whom a different permanent tablespace is not specified. The `tablespace` must already exist in the source database. Because the tablespace already exists, you cannot specify the `DATAFILE` clause or the `extent_management_clause` when creating a PDB with the `create_pdb_from_xml` clause.

***pdb\_storage\_clause***

Use this clause to specify storage limits for the new PDB. Refer to [\*pdb\\_storage\\_clause\*](#) for the full semantics of this clause.

***path\_prefix\_clause***

Use this clause to ensure that all directory object paths associated with the PDB are restricted to the specified directory or its subdirectories. Refer to [\*path\\_prefix\\_clause\*](#) for the full semantics of this clause.

***tempfile\_reuse\_clause***

Specify TEMPFILE REUSE to instruct the database to format and reuse a temp file associated with the new PDB if it already exists. Refer to [\*tempfile\\_reuse\\_clause\*](#) for the full semantics of this clause.

**HOST and PORT**

These clauses are useful only if you are creating a PDB that you plan to reference from a proxy PDB. This type of PDB is called a referenced PDB. Refer to [\*\*HOST and PORT\*\*](#) for the full semantics of these clauses.

***create\_pdb\_from\_mirror\_copy***

Specify this clause to create a pluggable database *new\_pdb\_name* using the prepared files of the mirror copy *mirror\_name*. The new PDB will be split from the source database using the prepared files created by the *prepare\_clause*.

- You must execute this clause from the root container.
- The meaning of the other optional parameters remains unchanged by this clause.
- You can only split one database from a prepared mirror copy. If you want to create additional splits, you must prepare a new mirror copy.
- You can specify the database link name after you have specified the mirror copy name in the *prepare\_clause* of the ALTER PLUGGABLE DATABASE statement. In addition, the current CDB name should match the target CDB name specified in the *prepare\_clause*. You must be a valid user in the CDB being referenced by the database link with the system privileges CREATE SESSION and CREATE PLUGGABLE DATABASE.
- If the database link name is omitted, then the base PDB name is looked up in the current CDB.

***using\_snapshot\_clause***

Specify this clause to create a PDB using an existing PDB snapshot that can be identified by its name, SCN, or timestamp.

If you create a PDB specifying SNAPSHOT COPY, then the new PDB will depend on the existence of the PDB snapshot. This will affect your ability to drop or purge the PDB.

***container\_map\_clause***

Specify this clause in CDB Root, Application Root or both to dynamically update changes as they happen to the new PDB.

You must note the following points with container maps:

- The `container_map_clause` is optional.
- The `add_partition_clause` will add a new partition to the container map defined in the Root (CDB Root and/or Application Root) of the new PDB.
- The `split_partition_clause` will split an existing partition of the container map defined in the Root (CDB Root and/or Application Root) of the new PDB.
- In the absence of `add_partition_clause` and `split_partition_clause`, container map defined in the Root of the new PDB is not updated.
- For PDB relocate, container map defined in the Root (CDB Root and/or Application Root) of the source PDB are automatically updated to reflect the “drop” of the source PDB.
- Dynamic maintenance of container map defined using hash partitioning is not supported

### Add a New Partition to a Range-Partitioned Container Map: Example

```
CREATE PLUGGABLE DATABASE cdb1_pdb3
  ADMIN USER IDENTIFIED BY manager
  FILE_NAME_CONVERT=('cdb1_pdb0, cdb1_pdb3')
  CONTAINER_MAP UPDATE (ADD PARTITION cdb1_pdb3 VALUES LESS THAN (100));
ALTER PLUGGABLE DATABASE cdb1_pdb3 OPEN
```

### Split an Existing Partition of a Range-Partitioned Container Map to Create a New Partition: Example

```
CREATE PLUGGABLE DATABASE cdb1_pdb4
  ADMIN USER IDENTIFIED BY manager
  FILE_NAME_CONVERT=('cdb1_pdb0, cdb1_pdb4')
  CONTAINER_MAP UPDATE (SPLIT PARTITION cdb1_pdb3
    AT (50)
    INTO
      (PARTITION cdb1_pdb3, PARTITION cdb1_pdb3))
ALTER PLUGGABLE DATABASE cdb1_pdb4 OPEN
```

### Verify Updated in Range-Partitioned Container Map : Example

```
SELECT partition_name, high_value
  FROM dba_tab_partitions
 WHERE table_name='MAP' AND table_owner='SYS'
```

### `pdb_snapshot_clause`

Specify this clause if you want to be able to create PDB snapshots.

- `NONE` is the default. It means that no snapshots of the PDB can be created.
- `MANUAL` means that the PDB snapshot can *only* be created manually.
- If snapshot interval is specified, PDB snapshots will be created automatically at specified interval. In addition, a user will also be able to create PDB snapshots manually
- If expressed in minutes, `snapshot_interval` must be less than 3000.
- If expressed in hours, `snapshot_interval` must be less than 2000.

### `create_pdb_decrypt_from_xml`

You must have the `SYSKM` privilege to execute this command.

For PDBs in **united** mode, the following restrictions apply:

- You must specify the clause if you are using a TDE protected database. Otherwise it is optional.
- You need not specify the clause for an isolated PDB.
- The wallet must be open in `ROOT`.
- The wallet file is copied in all cases: `NOCOPY`, `COPY`, and `MOVE`.

### Plugging a PDB from an XML Metadata File: Example

```
CREATE PLUGGABLE DATABASE CDB1_PDB2 USING '/tmp/cdb1_pdb2.xml' NOCOPY
KEYSTORE IDENTIFIED BY keystore_password DECRYPT USING transport_secret
```

### Plugging a PDB from an Archive File: Example

```
CREATE PLUGGABLE DATABASE CDB1_PDB1_1_C USING '/tmp/cdb1_pdb3.pdb' DECRYPT USING
transport_secret
```

For PDBs in **isolated** mode, you need not specify `DECRYPT USING transport_secret`. This is not required because the wallet file is copied during the creation of an unplugged PDB from an XML file. If you are creating a PDB from an archive file with the `.pdb` extension, the wallet file of the PDB is available in the zipped archive.

If the `ewallet.p12` file already exists at the destination, a backup is automatically initiated. The backup file has the following format: `ewallet_PLGDB_2017090517455564.p12`.

## Examples

### Creating a PDB by Using the Seed: Example

The following statement creates a PDB `salespdb` by using the seed in the CDB as a template. The administrative user `salesadm` is created and granted the `dba` role. The default tablespace assigned to any non-`SYSTEM` users for whom no permanent tablespace is assigned is `sales`. File names for the new PDB will be constructed by replacing `/disk1/oracle/dbs/pbseed/` in the file names in the seed with `/disk1/oracle/dbs/salespdb/`. All tablespaces that belong to `sales` must not exceed 2G. The location of all directory object paths associated with `salespdb` are restricted to the directory `/disk1/oracle/dbs/salespdb/`.

```
CREATE PLUGGABLE DATABASE salespdb
ADMIN USER salesadm IDENTIFIED BY password
ROLES = (dba)
DEFAULT TABLESPACE sales
DATAFILE '/disk1/oracle/dbs/salespdb/sales01.dbf' SIZE 250M AUTOEXTEND ON
FILE_NAME_CONVERT = ('/disk1/oracle/dbs/pbseed/',
'/disk1/oracle/dbs/salespdb/')
STORAGE (MAXSIZE 2G)
PATH_PREFIX = '/disk1/oracle/dbs/salespdb/';
```

### Cloning a PDB From an Existing PDB: Example

The following statement creates a PDB `newpdb` by cloning PDB `salespdb`. PDBs `newpdb` and `salespdb` are in the same CDB. Because no storage limits are explicitly specified, there is no limit on the amount of storage for `newpdb`. The files are copied from `/disk1/oracle/dbs/salespdb/` to `/disk1/oracle/dbs/newpdb/`. The location of all directory object paths associated with `newpdb` are restricted to the directory `/disk1/oracle/dbs/newpdb/`.

```
CREATE PLUGGABLE DATABASE newpdb FROM salespdb
  FILE_NAME_CONVERT = ('/disk1/oracle/dbs/salespdb/', '/disk1/oracle/dbs/
newpdb/')
  PATH_PREFIX = '/disk1/oracle/dbs/newpdb';
```

### Plugging a PDB into a CDB: Example

The following statement plugs the PDB `salespdb`, which was previously unplugged, into the CDB. The details about the metadata describing `salespdb` are stored in the XML file `/disk1/usr/salespdb.xml`. The XML file does not accurately describe the current locations of the files. Therefore, the `SOURCE_FILE_NAME_CONVERT` clause is used to indicate that the files are in `/disk2/oracle/dbs/salespdb/`, not `/disk1/oracle/dbs/salespdb/`. The `NOCOPY` clause indicates that the files are already in the correct location. All tablespaces that belong to `sales` must not exceed 2G. A file with the same name as the temp file specified in the XML file exists in the target location. Therefore, the `TEMPFILE REUSE` clause is required.

```
CREATE PLUGGABLE DATABASE salespdb
  USING '/disk1/usr/salespdb.xml'
  SOURCE_FILE_NAME_CONVERT =
    ('/disk1/oracle/dbs/salespdb/', '/disk2/oracle/dbs/salespdb/')
  NOCOPY
  STORAGE (MAXSIZE 2G)
  TEMPFILE REUSE;
```

## CREATE PMEM FILESTORE

### Purpose

You can create a persistent memory file store with this statement.

### Prerequisites

You must have `SYSDBA` privileges to execute `CREATE PMEM FILESTORE`.

You must execute this statement from `CDB$ROOT`.

### Syntax

***create\_pmem\_filestore::=***

## Semantics

### MOUNTPOINT

*file\_path* contains the final directory name and must match the PMEM file store name. If there is no match, the statement will fail.

You must start database instance with at least NOMOUNT mode.

It is recommended to use a spfile for the database init.ora file.

When you use a spfile, the CREATE PMEM FILESTORE command automatically writes the necessary init.ora parameters into the spfile to remember the configuration. If you do not use a spfile, you must explicitly add the required parameters to init.ora so that the next database instance startup will automatically mount the PMEM file store.

### Example

```
CREATE PMEM FILESTORE cloud_db_1 MOUNTPOINT '/corp/db/cloud_db_1'  
    BACKINGFILE '/var/pmem/foo_1.' SIZE 2T BLOCKSIZE 8K  
    AUTOEXTEND ON NEXT 10G MAXSIZE 3T
```

# CREATE PROCEDURE

### Purpose

Procedures are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the CREATE PROCEDURE statement to create a standalone stored procedure or a call specification.

A **procedure** is a group of PL/SQL statements that you can call by name. A **call specification** (sometimes called call spec) declares a Java method, a JavaScript method, or a third-generation language (3GL) routine so that it can be called from SQL and PL/SQL. The call spec tells Oracle Database which Java method, JavaScript function, or third-generation language (3GL) routine to invoke when a call is made. It also tells the database what type conversions to make for the arguments and return value.

Stored procedures offer advantages in the areas of development, integrity, security, performance, and memory allocation.

 See Also:

- [JavaScript Developer's Guide](#)
- [CREATE MLE MODULE](#)
- [CREATE MLE ENV](#)
- [Oracle Database Development Guide](#) for more information on stored procedures, including how to call stored procedures and for information about registering external procedures.
- [CREATE FUNCTION](#) for information specific to functions, which are similar to procedures in many ways.
- [CREATE PACKAGE](#) for information on creating packages. The `CREATE PROCEDURE` statement creates a procedure as a standalone schema object. You can also create a procedure as part of a package.
- [ALTER PROCEDURE](#) and [DROP PROCEDURE](#) for information on modifying and dropping a standalone procedure.
- [CREATE LIBRARY](#) for more information about shared libraries.

### Prerequisites

To create or replace a procedure in your own schema, you must have the `CREATE PROCEDURE` system privilege. To create or replace a procedure in another user's schema, you must have the `CREATE ANY PROCEDURE` system privilege.

To invoke a call spec, you may need additional privileges, for example, the `EXECUTE` object privilege on the C library for a C call spec.

To embed a `CREATE PROCEDURE` statement inside an Oracle precompiler program, you must terminate the statement with the keyword `END-EXEC` followed by the embedded SQL statement terminator for the specific language.

 See Also:

[Oracle Database PL/SQL Language Reference](#) or [Oracle Database Java Developer's Guide](#) for more information

### Syntax

Procedures are defined using PL/SQL. Alternatively they can refer to non-PL/SQL code such as Java, JavaScript, C, and others by means of call specifications. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to [Oracle Database PL/SQL Language Reference](#) for the PL/SQL syntax, semantics, and examples.

`create_procedure ::=`

(`plsql_procedure_source`: See *Oracle Database PL/SQL Language Reference*.)

## Semantics

### OR REPLACE

Specify `OR REPLACE` to re-create the procedure if it already exists. Use this clause to change the definition of an existing procedure without dropping, re-creating, and regranting object privileges previously granted on it. If you redefine a procedure, then Oracle Database recompiles it.

Users who had previously been granted privileges on a redefined procedure can still access the procedure without being regranted the privileges.

If any function-based indexes depend on the procedure, then Oracle Database marks the indexes `DISABLED`.

### See Also:

[ALTER PROCEDURE](#) for information on recompiling procedures

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the procedure does not exist, a new procedure is created at the end of the statement.
- If the procedure exists, this is the procedure you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error:  
 ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

### [ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the procedure is an editioned or noneditioned object if editioning is enabled for the schema object type `PROCEDURE` in *schema*. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

**plsql\_procedure\_source**

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the `plsql_procedure_source`.

## CREATE PROFILE

 **Note:**

Oracle recommends that you use the Database Resource Manager rather than this SQL statement to establish resource limits. The Database Resource Manager offers a more flexible means of managing and tracking resource use. For more information on the Database Resource Manager, refer to *Oracle Database Administrator's Guide*.

### Purpose

Use the `CREATE PROFILE` statement to create a **profile**, which is a set of limits on database resources. If you assign the profile to a user, then that user cannot exceed these limits.

To specify resource limits for a user, you must:

- Enable resource limits dynamically with the `ALTER SYSTEM` statement or with the initialization parameter `RESOURCE_LIMIT`. This parameter does not apply to password resources. Password resources are always enabled.
- Create a profile that defines the limits using the `CREATE PROFILE` statement
- Assign the profile to the user using the `CREATE USER` or `ALTER USER` statement

In a multitenant environment, different profiles can be assigned to a common user in the root and in a PDB. When the common user logs in to the PDB, a profile whose setting applies to the session depends on whether the settings are password-related or resource-related.

- Password-related profile settings are fetched from the profile that is assigned to the common user in the root. For example, suppose you assign a common profile `c##prof` (in which `FAILED_LOGIN_ATTEMPTS` is set to 1) to common user `c##admin` in the root. In a PDB that user is assigned a local profile `local_prof` (in which `FAILED_LOGIN_ATTEMPTS` is set to 6.) Common user `c##admin` is allowed only one failed login attempt when he or she tries to log in to the PDB where `loc_prof` is assigned to him.
- Resource-related profile settings specified in the profile assigned to a user in a PDB get used without consulting resource-related settings in a profile assigned to the common user in the root. For example, if the profile `local_prof` that is assigned to user `c##admin` in a PDB has `SESSIONS_PER_USER` set to 2, then `c##admin` is only allowed only 2 concurrent sessions when he or she logs in to the PDB `loc_prof` is assigned to him, regardless of value of this setting in a profile assigned to him in the root.

**See Also:**

*Oracle Database Security Guide* for a detailed description and explanation of how to use password management and protection

**Prerequisites**

To create a profile, you must have the CREATE PROFILE system privilege.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root. To specify CONTAINER = CURRENT, the current container must be a pluggable database (PDB).

**See Also:**

- [ALTER SYSTEM](#) for information on enabling resource limits dynamically
- *Oracle Database Reference* for information on the RESOURCE\_LIMIT parameter
- [CREATE USER](#) and [ALTER USER](#) for information on profiles

**Syntax**

*create\_profile ::=*

*resource\_parameters ::=*

(*size\_clause*::=

*password\_parameters*::=

## Semantics

### *profile*

Specify the name of the profile to be created. The name must satisfy the requirements listed in "Database Object Naming Rules". Use profiles to limit the database resources available to a user for a single call or a single session.

In a non-CDB, a profile name cannot begin with C## or c##.

 **Note:**

A multitenant container database is the only supported architecture in Oracle Database 21c and later releases. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

In a CDB, the requirements for a profile name are as follows:

- The name of a **common profile** must begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. By default, the prefix is `C##`.
- The name of a **local profile** must not begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. Regardless of the value of `COMMON_USER_PREFIX`, the name of a local profile can never begin with `C##` or `c##`.

 **Note:**

If the value of `COMMON_USER_PREFIX` is an empty string, then there are no requirements for common or local profile names with one exception: the name of a local profile can never begin with `C##` or `c##`. Oracle recommends against using an empty string value because it might result in conflicts between the names of local and common profiles when a PDB is plugged into a different CDB, or when opening a PDB that was closed when a common user was created.

Oracle Database enforces resource limits in the following ways:

- If a user exceeds the `CONNECT_TIME` or `IDLE_TIME` session resource limit, then the database rolls back the current transaction and ends the session. When the user process next issues a call, the database returns an error.
- If a user attempts to perform an operation that exceeds the limit for other session resources, then the database aborts the operation, rolls back the current statement, and immediately returns an error. The user can then commit or roll back the current transaction, and must then end the session.
- If a user attempts to perform an operation that exceeds the limit for a single call, then the database aborts the operation, rolls back the current statement, and returns an error, leaving the current transaction intact.

## MANDATORY

Specify the keyword `MANDATORY` to create a generic mandatory profile in `CDB$ROOT`. You can use the mandatory profile to enforce password complexity requirements for database user accounts across the entire CDB or individual PDBs using the profile parameter `password_verify_function`.

The mandatory profile adds the password complexity requirement in addition to existing profile limits for common and local users. A PDB administrator cannot remove the password

complexity requirement and allow users to set insecure shorter passwords, because mandatory profiles, just like common profiles, can only be altered in CDB\$ROOT .

You can only use `password_verify_function` and `password_grace_time` profile parameters to define the limits for the mandatory profile.

Use the profile parameter `password_grace_time` to specify a grace period for user accounts in violation of mandatory password complexity requirements and whose passwords have to be changed. User accounts imported using Oracle Data Pump are checked for password compliance against the mandatory profile and forced to change their passwords. If the password is not changed within the grace period, further connections are rejected.

The default value for `password_verify_function` is null. The default value for `password_grace_time` is 0.

### User-Created Password Complexity Function: Example

The example creates a password complexity function `my_mandatory_function` as the argument to `PASSWORD_VERIFY_FUNCTION`.

```
SQL> create or replace function my_mandatory_verify_function
  (username      varchar2,
   password      varchar2,
   old_password  varchar2)
  return boolean IS
begin
  -- mandatory verify function will always be evaluated regardless of the
  -- password verify function that is associated to a particular profile/user
  -- requires the minimum password length to be 8 characters
  if not ora_complexity_check(password, chars => 8) then
    return(false);
  end if;
  return(true);
end;
/
2   3   4   5   6   7   8   9   10  11  12  13  14  15  16  17
18
Function created.
```

### Create a Mandatory Profile: Example

The example creates mandatory profile c##cdb\_profile. LIMIT restricts the profile to use the only profile parameter allowed, the `PASSWORD_VERIFY_FUNCTION`. The `PASSWORD_VERIFY_FUNCTION` specifies the user-created password complexity function `my_mandatory_function`.

```
CREATE MANDATORY PROFILE c##cdb_profile LIMIT PASSWORD_VERIFY_FUNCTION
my_mandatory_function
CONTAINER = ALL ;
```

If you want to apply the mandatory user profile for all PDBs in the CDB, then you must do so in the CDB root using the `ALTER SYSTEM` statement.

### Apply the Mandatory Profile to the Entire CDB: Example

You must be in CDB\$ROOT to execute this statement.

```
ALTER SYSTEM SET MANDATORY_USER_PROFILE=c##cdb_profile;
```

If you want to apply the mandatory user profile for individual PDBs, then you must configure the `MANDATORY_USER_PROFILE` parameter in the `init.ora` file that is associated with the PDB.

### Apply the Mandatory Profile to an Individual PDB: Example

Open the `init.ora` file associated with the PDB and set the `MANDATORY_USER_PROFILE`.

```
MANDATORY_USER_PROFILE=c##cdb_profile;
```

You can use `SHOW PARAMETER` to find the current `MANDATORY_USER_PROFILE` setting.

The mandatory profile that you set in `init.ora` takes precedence over the mandatory profile that you set with the `ALTER SYSTEM` statement in the CDB root.

### Restrictions

- Only common users who have been commonly granted the `ALTER PROFILE` system privilege can alter or drop the mandatory profile, and only from the CDB root.
- Only a common user who has been commonly granted the `ALTER SYSTEM` privilege or has the `SYSDBA` administrative privilege can modify the `MANDATORY_USER_PROFILE` in the `init.ora` file.

#### Note:

- You can use fractions of days for all parameters that limit time, with days as units. For example, 1 hour is `1/24` and 1 minute is `1/1440`.
- You can specify resource limits for users regardless of whether the resource limits are enabled. However, Oracle Database does not enforce the limits until you enable them.

#### See Also:

- [Managing Security for Database Users](#)
- ["Creating a Profile: Example"](#)

### UNLIMITED

When specified with a resource parameter, `UNLIMITED` indicates that a user assigned this profile can use an unlimited amount of this resource. When specified with a password parameter, `UNLIMITED` indicates that no limit has been set for the parameter.

### DEFAULT

Specify `DEFAULT` if you want to omit a limit for this resource in this profile. A user assigned this profile is subject to the limit for this resource specified in the `DEFAULT` profile. The `DEFAULT` profile initially defines unlimited resources. You can change those limits with the `ALTER PROFILE` statement.

Any user who is not explicitly assigned a profile is subject to the limits defined in the `DEFAULT` profile. Also, if the profile that is explicitly assigned to a user omits limits for some resources

or specifies `DEFAULT` for some limits, then the user is subject to the limits on those resources defined by the `DEFAULT` profile.

#### *resource\_parameters*

##### **SESSIONS\_PER\_USER**

Specify the number of concurrent sessions to which you want to limit the user.

##### **CPU\_PER\_SESSION**

Specify the CPU time limit for a session, expressed in hundredths of seconds.

##### **CPU\_PER\_CALL**

Specify the CPU time limit for a call (a parse, execute, or fetch), expressed in hundredths of seconds.

##### **CONNECT\_TIME**

Specify the total elapsed time limit for a session, expressed in minutes.

##### **IDLE\_TIME**

Specify the permitted periods of continuous inactive time during a session, expressed in minutes. Long-running queries and other operations are not subject to this limit.

When you set an idle timeout of X minutes, note that the session will take X minutes, plus a couple of additional minutes to be terminated.

On the client application side, the error message shows up the next time, when the idle client attempts to issue a new command.

##### **LOGICAL\_READS\_PER\_SESSION**

Specify the permitted number of data blocks read in a session, including blocks read from memory and disk.

##### **LOGICAL\_READS\_PER\_CALL**

Specify the permitted number of data blocks read for a call to process a SQL statement (a parse, execute, or fetch).

##### **PRIVATE\_SGA**

Specify the amount of private space a session can allocate in the shared pool of the system global area (SGA). Refer to [size\\_clause](#) for information on that clause.

#### **Note:**

This limit applies only if you are using shared server architecture. The private space for a session in the SGA includes private SQL and PL/SQL areas, but not shared SQL and PL/SQL areas.

#### **COMPOSITE\_LIMIT**

Specify the total resource cost for a session, expressed in **service units**. Oracle Database calculates the total service units as a weighted sum of CPU\_PER\_SESSION, CONNECT\_TIME, LOGICAL\_READS\_PER\_SESSION, and PRIVATE\_SGA.

 **See Also:**

- [ALTER RESOURCE COST](#) for information on how to specify the weight for each session resource
- ["Setting Profile Resource Limits: Example"](#)

### ***password\_parameters***

Use the following clauses to set password parameters. Parameters that set lengths of time—that is, all the password parameters except FAILED\_LOGIN\_ATTEMPTS and PASSWORD\_REUSE\_MAX—are interpreted in number of days. For testing purposes you can specify minutes ( $n/1440$ ) or even seconds ( $n/86400$ ) for these parameters. You can also use a decimal value for this purpose (for example .0833 for approximately one hour). The minimum value is 1 second. The maximum value is 24855 days. For FAILED\_LOGIN\_ATTEMPTS and PASSWORD\_REUSE\_MAX, you must specify an integer.

#### **FAILED\_LOGIN\_ATTEMPTS**

Specify the number of consecutive failed attempts to log in to the user account before the account is locked. If you omit this clause, then the default is 10 times.

#### **PASSWORD\_LIFE\_TIME**

Specify the number of days the same password can be used for authentication. If you also set a value for PASSWORD\_GRACE\_TIME, then the password expires if it is not changed within the grace period, and further connections are rejected. If you omit this clause, then the default is 180 days.

 **See Also:**

*Oracle Database Security Guide* for information on setting PASSWORD\_LIFE\_TIME to a low value

### ***PASSWORD\_REUSE\_TIME and PASSWORD\_REUSE\_MAX***

These two parameters must be set in conjunction with each other. PASSWORD\_REUSE\_TIME specifies the number of days which need to pass before a user having this profile can reuse one of their earlier passwords. PASSWORD\_REUSE\_MAX specifies the number of password changes required before the current password can be reused. For these parameters to have any effect, you must specify a value for both of them.

- If you specify a value for both of these parameters, then the user cannot reuse a password until the password has been changed the number of times specified for PASSWORD\_REUSE\_MAX during the number of days specified for PASSWORD\_REUSE\_TIME.

For example, if you specify `PASSWORD_REUSE_TIME` to 30 and `PASSWORD_REUSE_MAX` to 10, then the user can reuse the password after 30 days if the password has already been changed 10 times.

- If you specify a value for either of these parameters and specify `UNLIMITED` for the other, then the user can never reuse a password.
- If you specify `DEFAULT` for either parameter, then Oracle Database uses the value defined in the `DEFAULT` profile. By default, the `PASSWORD_REUSE_TIME` and `PASSWORD_REUSE_MAX` parameters are set to `UNLIMITED` in the `DEFAULT` profile. If you have not changed the default setting of `UNLIMITED` in the `DEFAULT` profile, then the database treats the value for that parameter as `UNLIMITED`.
- If you set both of these parameters to `UNLIMITED`, then the database ignores both of them. This is the default if you omit both parameters.

#### **PASSWORD\_LOCK\_TIME**

Specify the number of days an account will be locked after the specified number of consecutive failed login attempts. If you omit this clause, then the default is 1 day.

#### **PASSWORD\_GRACE\_TIME**

Specify the number of days after the grace period begins during which a warning is issued and login is allowed. If you omit this clause, then the default is 7 days.

#### **INACTIVE\_ACCOUNT\_TIME**

Specify the permitted number of consecutive days of no logins to the user account, after which the account will be locked. The minimum value is 15 days. The maximum value is 24855. If you omit this clause, then the default is `UNLIMITED`.

#### **PASSWORD\_VERIFY\_FUNCTION**

You can pass a PL/SQL password complexity verification script as an argument to `CREATE PROFILE` by specifying `PASSWORD_VERIFY_FUNCTION`. Oracle Database provides a default script, but you can write your own function or use third-party software instead.

- For *function*, specify the name of the password complexity verification function. The function must exist in the `SYS` schema, and you must have `EXECUTE` privilege on the function.
- Specify `NULL` to indicate that no password verification is performed.

If you specify *expr* for any of the password parameters, then the expression can be of any form except scalar subquery expression.

#### **Restriction on Password Parameters**

When you assign a profile to an external user or a global user, the password parameters do not take effect for that user.

#### **See Also:**

["Setting Profile Password Limits: Example"](#)

#### **PASSWORD\_ROLLOVER\_TIME**

You must configure a non-zero limit for the `PASSWORD_ROLLOVER_TIME` user profile parameter in order to enable the gradual database password rollover. You can configure this parameter using `CREATE PROFILE` or `ALTER PROFILE`.

Use `expr` to specify a value for `PASSWORD_ROLLOVER_TIME` in days. You must specify hours as a fraction of one day. For example, if you want to set the limit to four hours, `expr` would be `4/24`.

The granularity of the `PASSWORD_ROLLOVER_TIME` limit value is one second. For example, you can have a limit of one hour plus three minutes and five seconds by providing an `expr` like this: `( 1/24 ) + ( 3/1440 ) + ( 5/86400 )`.

The default setting for `PASSWORD_ROLLOVER_TIME` is 0, which means that gradual password rollover is disabled.

### Example

The example sets the gradual password rollover time period to 1 day:

```
CREATE PROFILE usr_prof LIMIT PASSWORD_ROLLOVER_TIME 1
```

Limits on `PASSWORD_ROLLOVER_TIME`:

- Specify a value of 0 for `PASSWORD_ROLLOVER_TIME` if you want to disable the password rollover period.
- Specify a positive value for `PASSWORD_ROLLOVER_TIME` to enable the password rollover feature for all users who are members of the profile.
- The minimum value you can specify for `PASSWORD_ROLLOVER_TIME` is one hour. You do this by entering `1/24`. If you want to set the password rollover time to six hours, you enter `6/24` as the value for `PASSWORD_ROLLOVER_TIME`.
- The value for `PASSWORD_ROLLOVER_TIME` cannot exceed either 60 days, or the current value of the `PASSWORD_GRACE_TIME` limit of the profile, or the current value of the `PASSWORD_LIFE_TIME` limit of the profile; whichever is lowest.

To find user accounts that are currently in the password rollover period, query the `ACCOUNT_STATUS` column of the `DBA_USERS` data dictionary view. The status will be `IN ROLLOVER`.

The password rollover period begins the moment the user changes their password.

#### See Also:

Configuring Authentication

### CONTAINER Clause

The `CONTAINER` clause applies when you are connected to a CDB. However, it is not necessary to specify the `CONTAINER` clause because its default values are the only allowed values.

- To create a common profile, you must be connected to the root. You can optionally specify `CONTAINER = ALL`, which is the default when you are connected to the root.

- To create a local profile, you must be connected to a PDB. You can optionally specify CONTAINER = CURRENT, which is the default when you are connected to a PDB.

## Examples

### Creating a Profile: Example

The following statement creates the profile new\_profile:

```
CREATE PROFILE new_profile
  LIMIT PASSWORD_REUSE_MAX 10
    PASSWORD_REUSE_TIME 30;
```

### Setting Profile Resource Limits: Example

The following statement creates the profile app\_user:

```
CREATE PROFILE app_user LIMIT
  SESSIONS_PER_USER      UNLIMITED
  CPU_PER_SESSION        UNLIMITED
  CPU_PER_CALL           3000
  CONNECT_TIME            45
  LOGICAL_READS_PER_SESSION DEFAULT
  LOGICAL_READS_PER_CALL   1000
  PRIVATE_SGA              15K
  COMPOSITE_LIMIT         5000000;
```

If you assign the app\_user profile to a user, then the user is subject to the following limits in subsequent sessions:

- The user can have any number of concurrent sessions.
- In a single session, the user can consume an unlimited amount of CPU time.
- A single call made by the user cannot consume more than 30 seconds of CPU time.
- A single session cannot last for more than 45 minutes.
- In a single session, the number of data blocks read from memory and disk is subject to the limit specified in the DEFAULT profile.
- A single call made by the user cannot read more than 1000 data blocks from memory and disk.
- A single session cannot allocate more than 15 kilobytes of memory in the SGA.
- In a single session, the total resource cost cannot exceed 5 million service units. The formula for calculating the total resource cost is specified by the ALTER RESOURCE COST statement.
- Since the app\_user profile omits a limit for IDLE\_TIME and for password limits, the user is subject to the limits on these resources specified in the DEFAULT profile.

### Setting Profile Password Limits: Example

The following statement creates the app\_user2 profile with password limits values set:

```
CREATE PROFILE app_user2 LIMIT
  FAILED_LOGIN_ATTEMPTS 5
  PASSWORD_LIFE_TIME 60
  PASSWORD_REUSE_TIME 60
```

```
PASSWORD_REUSE_MAX 5
PASSWORD_VERIFY_FUNCTION ora12c_verify_function
PASSWORD_LOCK_TIME 1/24
PASSWORD_GRACE_TIME 10
INACTIVE_ACCOUNT_TIME 30;
```

This example uses the default Oracle Database password verification function, `ora12c_verify_function`. Refer to *Oracle Database Security Guide* for information on using this verification function provided or designing your own verification function.

## CREATE PROPERTY GRAPH

### Purpose

Use `CREATE PROPERTY GRAPH` to create a property graph from existing schema objects. The schema object can be a table, an external table, a materialized view or a synonym of the table, external table, or materialized view.

### Prerequisites

You need the `CREATE PROPERTY GRAPH` privilege to create a property graph in your own schema. To create a property graph in any schema except `SYS` and `AUDSYS`, you must have the `CREATE ANY PROPERTY GRAPH` privilege.

### Syntax

(`edge_tables_clause ::= , graph_options`)

**`vertex_tables_clause ::=`**

**`vertex_table_definition ::=`**

`graph_table_level_and_properties`

*graph\_element\_name\_and\_key ::=*

*graph\_element\_object\_name ::=*

*graph\_element\_key ::=*

*graph\_table\_label\_and\_properties ::=*

*graph\_table\_label\_properties\_clause ::=*

*graph\_table\_properties\_alternatives ::=*

*column\_name\_list*::=

*column\_or\_expression*::=

*graph\_table\_label\_clause*::=

*edge\_tables\_clause*::=

*edge\_tables\_definition*::=

*graph\_table\_level\_and\_properties*

*vertex\_table\_reference*::=

`graph_options ::=`

## Semantics

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the property graph does not exist, a new property graph is created at the end of the statement.
- If the property graph exists, the existing property graph is what you have at the end of the statement. A new one is not created because the older one is detected.

Using `IF EXISTS` with `CREATE` results in the following error: `Incorrect IF NOT EXISTS clause for CREATE statement`.

You must create a property graph with the `vertex_tables_clause`.

Specify the schema to contain the property graph. If you omit schema, then Oracle Database creates the graph in your own schema.

The name of the property graph must not be used by any other object in the same schema, because property graphs share the name space used for tables and views. `ORA-00955` is raised in the case of name conflicts.

Specify `OR REPLACE` to re-create the property graph, if it already exists. You can use this clause to change the definition of an existing property graph without dropping, re-creating, and regranting object privileges previously granted on it.

If any materialized views are dependent on the property graph, then those materialized views will be marked `UNUSABLE` and will require a full refresh to restore them to a usable state. Invalid materialized views cannot be used by query rewrite and cannot be refreshed until they are recompiled.

### `vertex_tables_clause`

The `vertex_tables_clause` lets you define one or more vertex tables for the property graph. A `vertex_table_definition` needs to specify the underlying object name. It can optionally specify more items (like labels and properties) as explained below.

You can define a property graph by specifying just the name of the underlying object used to define the graph element table. In this case a default label with the same name as the underlying table is created and all the columns are exposed as graph properties.

The object name can be the name of a table, an external table, a materialized view, or a synonym of a table or materialized view.

The object name can be qualified by specifying the schema it resides in. This means that you can use objects from other schemas to define a graph element table. If no option is specified, the name of the specified object is used as the name of the graph element table.

### **Example: Create a Property Graph with Vertex Table**

In the following example, the vertex table name `my_table_1` is the name of underlying object `my_table_1`.

```
CREATE PROPERTY GRAPH "myGraph" VERTEX TABLES (my_table_1);
```

### **Example: Create a Property Graph with a Schema-Qualified Vertex Table**

In the following example, the name `my_table_1` is qualified by the schema `other_schema` and the vertex table name is the name of underlying object `my_table_1`.

```
CREATE PROPERTY GRAPH "myGraph" VERTEX TABLES (other_schema.my_table_1);
```

### ***graph\_element\_name\_and\_key***

The `graph-element-name-and-key` clause lets you specify:

- The name of the schema object to be used for defining a graph element table. The name of the graph element table defaults to the `graph_element_object_name` without the schema qualification, if an `AS` clause is not used to provide an alternative name.
- One or more column names used to explicitly specify what columns of the underlying object are used to identify a row in that underlying object.

Graph element table names are defined in a name space specific to the property graph: they do not conflict with the names of schema objects, nor with the names of graph element tables defined in other property graphs. This implies also that an edge table cannot use the name of a vertex table. Graph element table names follow the same rules as other identifiers: they may be quoted to indicate case-sensitivity, and are limited by default to 128 characters. Any subsequent symbolic references to a graph element table in the DDL statement must use the graph element table name, not the name of its underlying object. In particular, you must use the graph element table name when you define the source and destination vertex table of an edge table.

`graph_element_object_name` identifies the table or the materialized view directly or indirectly using a synonym for the table or the materialized view.

You can omit the clause `graph-element-key` in the following cases:

- The clause `graph_element_object_name` identifies a base table with a single primary key constraint. The primary key constraint takes precedence over any unique key that might also be defined.
- The clause `graph_element_object_name` identifies a base table without primary keys and a single unique key constraint where all columns are not nullable.

You must specify `graph-element-key` when `object_name` identifies a materialized view.

### **Example**

The example shows the ways `graph-element-key` is used. In vertex table `VT3` it is used to specify a composite key made of multiple columns of the underlying table. Vertex table `ALTVT2` is defined from the same underlying object used to define vertex table `VT2`, but a different column of that object (`PK4`) is specified as identifier for its vertices. It is assumed that vertex table `VT1` has a primary key constraint or unique key with not null columns.

```
CREATE PROPERTY GRAPH "myGraph"
  VERTEX TABLES (
    VT1,
    VT2 KEY(PK2),
    VT3 KEY(PK31, PK32),
    VT2 AS ALTVT2 KEY(PK4)
  );
```

Note that a same underlying object VT2 can be used to define another graph element table using the same primary key used to define other graph element tables from VT2. So in the example above, specifying PK2 instead of PK4 for ALTVT2 is allowed.

When the *graph-element-key* clause is present, all the declared column names must match column names of the underlying object of the graph element table.

When the *graph-element-key* clause is omitted, the database will infer the columns from the constraints of the underlying object. If multiple primary or unique key constraints are defined for that object, inferring a key fails and an error is raised. Note that the primary constraint is only used to infer the key for the graph element table, no dependency to the constraint is created as a result of this inference. This means that the constraint may be dropped later without invalidating the graph or impact to its definition.

You can change this behavior and create a dependency to the constraint with the ENFORCED MODE option.

You can define multiple graph element tables from the same object. For example, a table may act as a different edge table in the same graph. You can also define a graph from tables from different schemas but with the same name. In both cases you must take care to avoid name collisions by specifying an alternative graph element table name with the optional AS clause.

### Example: Create a Property Graph with the AS Clause

```
CREATE PROPERTY GRAPH "myGraph" VERTEX TABLES (my_table_1,
other_schema.my_table_1 AS my_table2);
```

### Restrictions

Restrictions that apply on primary key constraints also apply on vertex and edge table keys:

- Columns of the following built-in data types can be used to define keys of vertex or edge tables: VARCHAR2, NVARCHAR2, NUMBER, BINARY\_FLOAT, BINARY\_DOUBLE, CHAR, NCHAR, DATE, INTERVAL (both YEAR TO MONTH and DAY TO SECOND), and TIMESTAMP (but not TIMESTAMP WITH TIME ZONE).
- A composite key cannot exceed 32 columns.

### *edge\_tables\_clause*

Use *edge\_tables\_clause* to specify one or more *edge\_table\_definition* clauses. Each *edge\_table\_definition* clause specifies the underlying object used to define the edge table of the graph.

***edge\_table\_definition***

Use *edge\_table\_definition* to explicitly define the vertex table that acts as the source of the edge, and the vertex table that acts as the destination of the edge using the keywords `SOURCE` and `DESTINATION`.

***vertex\_table\_reference***

The source and destination of the edge specify a *vertex\_table\_reference*. The *vertex\_table\_reference* specifies three components:

- The graph element name of a vertex table, `graph_element_name`
- A list of columns of the edge table to be treated as foreign key `graph_element_key`.
- A list of columns of the referenced vertex table to be treated as referenced keys `column_name_list`

The `graph_element_name` of a *vertex\_table\_reference* clause must be defined by a preceding *vertex\_tables\_definition* clause. A vertex table name defined in the *vertex\_tables\_definition* may be used to define multiple edge table definitions, either as a source for the edge, a destination, or both.

**Example**

Given the following vertex tables defined as follows:

```
CREATE PROPERTY GRAPH "myGraph"
    VERTEX TABLES (
        VT1,
        VT2 KEY(PK2),
        VT3 KEY(PK31, PK32),
        VT2 AS ALTVT2 KEY(PK4)
    )
    EDGE TABLES (
        E1 SOURCE VT1
            DESTINATION VT2,
        E2 SOURCE      KEY(FK1) REFERENCES VT1 (PK1)
            DESTINATION KEY(FK2) REFERENCES VT2 (PK2),
        E3 SOURCE      KEY(FK1) REFERENCES VT1 (PK1)
            DESTINATION VT2,
        E4 SOURCE VT1
            DESTINATION KEY(FK5) REFERENCES VT2 (RK5))
;
```

Both vertex-table-reference from edge table `E1` to, respectively, source table `VT1` and destination table `VT2` are declared implicitly. When using this syntax, the user relies on the database to infer source and destination keys from existing foreign-key constraints between `E1` and, respectively, `VT1` and `VT2`. In this case, there must be exactly only foreign-key constraints between `E1` and `VT1` (respectively, `VT2`).

If that is not the case an error is raised. Note that the foreign key constraint is only used to infer the foreign key relationships between an edge table and its source and destination vertex tables. No dependency to the foreign key constraint is created as a result of this inference. This means that the constraint may be dropped later without invalidating the graph or impact to its definition.

In contrast, both vertex-table-references from edge table `E2`, respectively, source vertex table `VT1` and destination vertex table `VT2` are declared explicitly. This syntax is mandatory when

there are no or multiple foreign constraints defined between E2 and its referenced vertex tables.

Implicit and explicit syntax can be mixed, as shown for edge table E3 and E4, wherein the former uses an explicit syntax only of the source table, while the latter uses it only for the destination table.

Note that the `column_name_list` clause that specifies the columns of the underlying object for the referenced vertex table to be treated as referenced key don't necessarily match the columns specified in the graph-element-key sub-clause of the vertex-definition clause that defined the referenced vertex table. This is illustrated with edge table E4 from the example above: the referenced key specified for VT2 is RK5, whereas the key that was specified in the vertex table definition clause for VT2 was PK2.

#### ***graph\_table\_label\_and\_properties***

Use `graph_table_label_and_properties` to specify the labels and properties of a graph. Then you can formulate graph queries using the labels of a graph and the properties defined by these labels.

#### **Graph Labels and Properties**

You can associate graph element tables with labels that expose the columns of the underlying object as properties. A label has a name and declares a mapping of property names to columns of the underlying object for a given graph element table. Labels give you a way to refer to one or more graph element tables in a graph query using a same label name. Properties give you a way to refer to columns of one or more graph element tables using a same, possibly label qualified, property name.

You can associate one label to multiple graph element tables, provided that all the graph element tables that share this label declare the same property name. The columns or value expressions exposed by the same property name must have union compatible types.

A graph element table may be associated with multiple labels.

Graph element tables are always associated with at least one label. If none is defined explicitly, a label is assigned automatically with the same name as the graph element table.

Declaring labels and properties is optional. All the following ways to explicitly declare properties and labels are valid:

- Only properties using `graph_table_label_properties_clause`
- Only labels using `graph_table_label_clause`
- Both properties and labels using `graph_table_label_properties_clause`
- No properties or labels

#### ***graph\_table\_label\_properties\_clause***

The properties are derived from columns or SQL value expressions of columns of the underlying object used to define the graph element table. By default, all visible columns are mapped to properties and the names of the properties default to the names of these columns. Pseudo-columns cannot be exposed as a property.

The `graph_table_label_properties_clause` provides the following options:

- PROPERTIES [ ARE ] ALL COLUMNS

All visible columns of the graph element table are exposed as properties of the label with the same names as the column names. (This is the default when no properties are specified.) Note that all visible columns that are used as keys will also be exposed as properties.

- PROPERTIES [ ARE ] ALL COLUMNS EXCEPT(*column\_name\_list*)

All visible columns are exposed as properties of the label except for the ones explicitly listed. This option is useful, if the number of columns not supposed to be exposed as properties is small compared to the number of columns exposed as properties.

- PROPERTIES (*column\_name\_list*)

Only the columns explicitly listed become properties of the label with the same names as the column names. This option is useful, if the number of columns exposed as properties is small compared to the number of columns not supposed to be exposed as properties, or if the user wants to expose invisible columns. It is also useful when renaming some or all of the properties is necessary, as shown in the following:

- PROPERTIES(*column\_name\_list AS property\_name*)

Only the columns explicitly listed become properties of the label. If *AS property\_name* is appended to the *column\_name*, then the *property\_name* is used as the property name, otherwise the property name defaults to the column name. A property name can only be defined once per label. The *AS* clause is useful to enable association of one label to multiple graph element tables.

- PROPERTIES (*value\_expression AS property\_name, ...*)

It is possible to define a property as an expression over columns of the underlying object used to define a graph element table. The *AS* clause is mandatory in this case. A value expression can be a scalar expression, or a function expression, or expression list. It can contain only the following forms of expression:

- Columns of the underlying object
- Constants: strings or numbers
- Deterministic functions — either SQL built-in functions or PL/SQL functions

No other expression forms are valid (in particular, sub-query expressions and aggregate functions are invalid). The expression can only return a scalar data type. SQL operator used in the expression must be deterministic

- NO PROPERTIES

The label does not expose any column of the underlying object associated with the graph element table.

Note that for a given vertex or edge table, the properties exposed in the various labels applied to this vertex or edge table must have the same definition.

#### ***graph\_table\_properties\_alternatives***

You can control explicitly what columns are exposed as properties using the options of *graph\_table\_properties\_alternatives* clause.

Note that for implicit clauses, for example *ALL COLUMNS*, the list of exposed columns is determined when the graph is created. If you add additional columns to a table after you create the graph, for example you add a virtual column, the graph will not reflect the virtual column.

## Examples

The following example illustrates various uses of `graph_table_label_and_properties` for declaring labels associated to graph element tables (here only vertex tables) and their properties:

```
CREATE PROPERTY GRAPH "myGraph"
  VERTEX TABLES (
    HR.VT1,
    VT1 AS ALTVT1,
    VT2 LABEL "foo",
    VT3 NO PROPERTIES,
    VT4 PROPERTIES(C1),
    VT5 PROPERTIES(C1, C2 as P2),
    VT6 LABEL "bar" LABEL "weighted" NO PROPERTIES,
    VT7 LABEL "bar2" ALL COLUMNS ARE PROPERTIES EXCEPT (C3),
    VT8 LABEL "weighted" NO PROPERTIES DEFAULT LABEL,
    VT9 PROPERTIES(Cx + Cy * 0.15 AS PX, Cz AS PZ),
    VT10 PROPERTIES(JSON_VALUE(JCOL,
      '$.person.creditScore[0]' returning number) AS CREDITSCORE,
      PROPERTIES(XMLCAST(XMLQUERY('/purchaseOrder/poDate'
        PASSING XCOL RETURNING CONTENT) AS DATE) AS PURCHASEDATE
    );
  );
```

The meaning of each vertex table definition of the example:

- Vertex table `VT1` defines (implicitly) a single label `VT1` that exposes all the visible columns of the underlying object `HR.VT1`. This is the default when no options to specify label or property are used.
- Vertex table `ALTVT1` defines (implicitly) a single label `ALTVT1` that exposes all the visible columns of the underlying object `VT1`. If object name `VT1` resolves to `HR.VT1`, both vertex tables `ALTVT1` and `VT1` exposes the same columns from the same underlying object `HR.VT1`.
- Vertex table `VT2` defines a single label `foo` that exposes all the visible columns of the underlying object `VT2`.
- Vertex table `VT3` defines (implicitly) a single label `VT3` without any properties. No columns from the underlying object `VT3` are exposed.
- Vertex table `VT4` defines (implicitly) a single label `VT4` with a single property `C1` that exposes the column `C1` of the underlying object `VT4`.
- Vertex table `VT5` defines (implicitly) a single label `VT5` with a two properties `C1` and `P2`, that exposes, respectively, column `C1` and `C2` of the underlying object `VT5`.
- Vertex table `VT6` defines two labels, `bar` and `weighted`, such that label `bar` exposes all visible columns of underlying object `VT6` as properties, while label `"weighted"` has no properties.
- Vertex table `VT7` defines a single label `bar2` that exposes all columns of the underlying object `VT3` but its column `C3`.
- Vertex table `VT8` defines two labels, `bar2` and `VT8` (via the `DEFAULT LABEL`). The former has no properties while the later exposes all columns as properties.
- Vertex table `VT9` defines (implicitly) a single label `VT9` with two properties `PX` and `PZ`, with `PX` exposing an expression over columns `Cx` and `Cy` of the underlying object `VT9`, while `PZ` exposes its column `Cz`.

- Vertex table VT10 defines one property CREDITSCORE that extracts creditScore value as number datatype from the JSON type column JCOL.
- Vertex table VT11 defines one property PURCHASEDATE that extracts purchase order date value as date datatype from the XMLtype column XCOL.

### ***graph\_options***

Use the OPTIONS clause to specify a comma separated list of options. Each option can appear only once. You can specify the mode of the graph, one of ENFORCED or TRUSTED. You can either allow or disallow mixed types in properties with the same name.

#### **ENFORCED or TRUSTED Mode**

Option ENFORCED on the property graph means that guarantees are enforced over the entire graph via constraints in the ENABLE VALIDATE state.

If you do not specify ENFORCED , the mode is TRUSTED. This is the default mode.

A property graph is in ENFORCED mode if :

- All of its graph element tables are defined with a primary key that matches an existing ENABLE VALIDATE primary key constraint, or a unique key constraint in the ENABLE VALIDATE state where all columns are not nullable.
- All vertex table references from edge tables are defined with a foreign key that matches an existing ENABLE VALIDATE foreign key constraint between the underlying objects for the edge and the vertex table respectively, that (foreign key constraint) defines the source or destination vertex table reference. Further, the foreign key columns must have a NOT NULL constraint, and a ENABLE VALIDATE primary key constraint, or both a unique and not null constraints, must be defined on the referenced keys for each of the source and destination table.

If neither one of these conditions is true, then the property graph is in TRUSTED mode. This is the default mode.

#### **Example: Creation of a Property Graph in Enforced Mode**

```
CREATE PROPERTY GRAPH "mygraph"
  VERTEX TABLES (VT1, VT2 KEY(PK2)),
  EDGE TABLES (
    ET1 SOURCE VT1 DESTINATION VT2,
    ET2 SOURCE KEY(FK2) REFERENCES VT2 (PK2) DESTINATION VT1)
  OPTIONS(ENFORCED MODE);
```

The DDL in the example fails if any of the following is true:

- If neither a primary key constraint, or exactly one unique key constraint on non nullable columns can be found for vertex table VT1, edge table ET1 or edge table ET2, regardless of the ENFORCED MODE option.
- If there is not exactly one foreign key between ET1 and its referenced tables VT1 and VT2, or between ET2 and its referenced table VT1, regardless of the ENFORCED MODE option.
- If neither a single primary key constraint on VT2.PK2, or a unique key constraint and NOT NULL constraint on VT2.PK2 can be found, as a result of the ENFORCED MODE option.
- If no foreign key constraint can be found between ET2.FK2 and its referenced table VT2.PK2, and there is neither a primary key constraint, or both a unique key and a NOT NULL constraint on VT2.PK2, as a result of the ENFORCED MODE option.

DDL operations on constraints on tables that form the underlying objects of a property graph can invalidate the graph if this one was successfully created with the ENFORCED MODE option and have no effect on the graph if this one was successfully created with the TRUSTED MODE option.

**Table 14-1 DDL Operations on Constraints that Causes Graph Created with the ENFORCED MODE Option to become Invalid**

| Operations                                                                                                                                                                                                                | Description                                                                                                                                                                                                                 |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>pkc is a PRIMARY KEY constraint in the statements below.</p> <pre>ALTER TABLE t DROP CONSTRAINT pkc;</pre> <pre>ALTER TABLE t DISABLE CONSTRAINT pkc;</pre> <pre>ALTER TABLE t ENABLE NOVALIDATE CONSTRAINT pkc;</pre> | If t is a graph element table e of G, and pkc is a primary or unique key constraint on columns used as keys for e, and G was in ENFORCED mode, G is changed to be in TRUSTED mode.                                          |
| <p>fkc is a FOREIGN KEY constraint in the statements below.</p> <pre>ALTER TABLE t DROP CONSTRAINT fkc;</pre> <pre>ALTER TABLE t DISABLE CONSTRAINT fkc;</pre> <pre>ALTER TABLE t ENABLE NOVALIDATE CONSTRAINT fkc;</pre> | If t is an edge table e of G, and fkc is a foreign key constraint on columns used as source or destination keys for e referencing columns of vertex table v, and G was in ENFORCED mode, G is changed to be in TRUSTED mode |

#### ALLOW or DISALLOW MIXED PROPERTY TYPES

DISALLOW means that the types of properties with same name should be exactly the same, regardless of the labels where they come. Use DISALLOW when you want to ensure that a given property has the same type across all labels.

ALLOW means that the types of properties with same name exposed in different labels can be distinct and of properties with same name coming from same label should be UNION compatible.

If you specify DISALLOW MIXED PROPERTY TYPES, the properties of a given name must have exactly the same type in every label. Note that this option also requires that you define a label associated with multiple graph element tables with the same data type.

The table summarizes the compatibility rules.

**Table 14-2 Compatibility Rules for Mixed Property Types**

| Options                                                              | ALLOW                          | DISALLOW         |
|----------------------------------------------------------------------|--------------------------------|------------------|
| Properties with same name in different definition of the same labels | Types must be UNION Compatible | Types must match |
| Properties with same name from different labels                      | Any                            | Types must match |

DISALLOW MIXED PROPERTY TYPES is the default.

### Dependencies Between Property Graph and its Underlying Objects

A property graph depends on the underlying objects it is based upon, tables, materialized views, or synonyms of tables or materialized views. Changes in these underlying objects can render the property graph invalid. Cursors that depend on the underlying objects are also invalidated. Queries against an invalid property graph in invalid state will error.

The following summarizes operations on dependent objects that cause a property graph to become invalid:

**Table 14-3 Operations on Dependent Objects that Invalidate a Property Graph**

| Operations                                                                                                       | Result                                                                                                                                                                 |
|------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DROP TABLE t ;<br>DROP [PUBLIC] SYNONYM t;<br>DROP MATERIALIZED VIEW t;<br>CREATE OR REPLACE [PUBLIC] SYNONYM t; | If t is used to define a graph element table e of graph G, then G becomes invalid.                                                                                     |
| RENAME t TO t2;                                                                                                  | If t is used to defined a graph element table e of graph G, then G becomes invalid                                                                                     |
| ALTER TABLE for dropping an unused column C of table t                                                           | If t is used to defined a graph element table e of graph G, then G becomes invalid                                                                                     |
| ALTER TABLE                                                                                                      |                                                                                                                                                                        |
| ALTER TABLE t RENAME C TO C2;                                                                                    | If t is used to defined a graph element table e of graph G and at least one label applied to e define a property as an SQL operator expression, then G becomes invalid |
| ALTER TABLE for modifying the type of a column C of table t                                                      | If t is used to defined a graph element table e of graph G, then G becomes invalid                                                                                     |

Other DDL operations to alter dependent tables, views, or synonyms do not invalidate the property graph.

Note also that using a materialized view to define vertex or edge tables in a property graph creates a dependency to the container table for the view, not directly to the materialized view schema object. This has the following implications:

- When dropping a materialized view but preserving its table (i.e., using `PRESERVE TABLE`), the property graph remains valid.
- When dropping one of the tables, views, or synonyms used in the definition of the materialized view, the materialized view becomes invalid, but the property graph remains valid as it only depends on the container table.

This behavior is similar to the behavior of views defined over a materialized view.

### Revalidating a Property Graph

Changes to the underlying objects of a property graph may invalidate the graph. An invalid state indicates that the metadata of the property graph describes an incorrect definition with respect to the property graph data model.

You can revalidate the property graph by redefining it with CREATE OR REPLACE PROPERTY GRAPH .

Sometimes however a graph may report an invalid state when it is actually valid. This can happen when the dependencies of the graph to its underlying objects are too coarse. When this happens you can revalidate the graph using ALTER PROPERTY GRAPH COMPILE instead of redefining it.

 **See Also:**

[ALTER PROPERTY GRAPH](#)

## Examples

### Example: Property Graph Without Explicit Labels or Properties

In the example a property graph `myGraph` is created without labels or properties. A label with name `mytable` is automatically associated with the vertex table `mytable` defined over the object `myschema`. A label with name `T2` is automatically associated with the vertex table `T2` defined over the object `mytable2`.

All the columns of the underlying tables `mytable` and `T2` are exposed as properties. The property name is the column name.

```
CREATE PROPERTY GRAPH "myGraph"  
    VERTEX TABLES ("myschema". "mytable", "mytable2" AS T2);
```

### Example: Property Graph With An Explicit Label

In the example the vertex table `mytable` is associated with the label `person`.

All the columns of `mytable` are exposed as properties.

```
CREATE PROPERTY GRAPH "myGraph"  
    VERTEX TABLES ("myschema". "mytable" LABEL "person");
```

If a label with the name of the graph element table is also needed, you have to explicitly declare it in addition to the `person` label. You can do this by declaring another explicit label that has the name of the graph element table, or by adding a DEFAULT LABEL.

The following vertex table declarations are semantically equivalent and all associate the graph element table `mytable` with the label `mytable`:

```
CREATE PROPERTY GRAPH "myGraph"  
    VERTEX TABLES ("myschema". "mytable" LABEL "mytable");
```

```
CREATE PROPERTY GRAPH  
    VERTEX TABLES ("myschema". "mytable" DEFAULT LABEL);
```

```
CREATE PROPERTY GRAPH  
    VERTEX TABLES ("myschema". "mytable" AS "mytable");
```

```
CREATE PROPERTY GRAPH  
    VERTEX TABLES ("myschema". "mytable");
```

**Example: Property Graph With Multiple Labels**

You can associate multiple labels to the same graph element. The example vertex table `mytable` is associated with two labels `foo` and `bar`.

All the columns of `mytable` are exposed as properties.

```
CREATE PROPERTY GRAPH "myGraph"
  VERTEX TABLES ("myschema". "mytable" LABEL "foo" LABEL "bar");
```

**Example: Property Graph With One Label Associating Multiple Graph Elements**

The example shows a property graph `mygraph` where the shared weighted label associates two vertex tables `mytable1` and `mytable2` and two edge tables `E1` and `E2`.

All the columns of `mytable1` and `mytable2` are exposed as properties.

```
CREATE PROPERTY GRAPH "myGraph"
  VERTEX TABLES (
    "mytable1" LABEL "foo" LABEL "weighted",
    "mytable2" LABEL "weighted"),
  EDGE TABLES (
    "E1" SOURCE "mytable1" DESTINATION "mytable2" LABEL "weighted"
    "E2" SOURCE "mytable2" DESTINATION "mytable1" LABEL "weighted"
  );
```

## CREATE RESTORE POINT

**Purpose**

Use the `CREATE RESTORE POINT` statement to create a **restore point**, which is a name associated with a timestamp or an SCN of the database. A restore point can be used to flashback a table or the database to the time specified by the restore point without the need to determine the SCN or timestamp. Restore points are also useful in various RMAN operations, including backups and database duplication. You can use RMAN to create restore points in the process of implementing an archival backup.

 **See Also:**

- [Oracle Database Backup and Recovery User's Guide](#) for more information on creating and using restore points and guaranteed restore points, for information on database duplication, and for information on archival backups
- [FLASHBACK DATABASE](#), [FLASHBACK TABLE](#), and [DROP RESTORE POINT](#) for information on using and dropping restore points

**Prerequisites**

To create a normal restore point, you must have the `SELECT ANY DICTIONARY`, `FLASHBACK ANY TABLE`, `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege.

To create a guaranteed restore point, you must fulfill *one* of the following conditions:

- You must connect AS `SYSDBA`, or AS `SYSBACKUP`, or AS `SYSDG`.
- You must have been granted the `SYSDBA` privilege and be using a multitenant database.

- You must be running as user `SYS`, and be using a multitenant database.

To view or use a restore point, you must have the `SELECT ANY DICTIONARY`, `FLASHBACK ANY TABLE`, `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege or the `SELECT_CATALOG_ROLE` role.

You can create a restore point on a primary or standby database. The database can be open, or mounted but not open. If the database is mounted, then it must have been shut down consistently before being mounted unless it is a physical standby database.

You must have created a fast recovery area before creating a guaranteed restore point. You need not enable flashback database before you create the guaranteed restore point. The database must be in `ARCHIVELOG` mode if you are creating a guaranteed restore point.

You need not enable flashback database before you create a normal restore point, because normal restore points have other applications besides `FLASHBACK DATABASE`. However, you would need to have enabled flashback database before you create a normal restore point, if you intend to perform a `FLASHBACK DATABASE` to that normal restore point.

You can create, use, or view a restore point when connected to a multitenant container database (CDB) as follows:

- To create a normal CDB restore point, the current container must be the root and you must have the `SELECT ANY DICTIONARY` or `FLASHBACK ANY TABLE` system privilege, either granted commonly or granted locally in the root, or the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege granted commonly.
- To create a guaranteed CDB restore point, the current container must be the root and you must have the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege granted commonly.
- To view a CDB restore point, the current container must be the root and you must have the `SELECT ANY DICTIONARY` or `FLASHBACK ANY TABLE` system privilege or the `SELECT_CATALOG_ROLE` role, either granted commonly or granted locally in the root, or the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege granted commonly, or the current container must be a PDB and you must have the `SELECT ANY DICTIONARY`, `FLASHBACK ANY TABLE`, `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege, granted commonly or granted locally in that PDB.
- To use a CDB restore point, you must have the `SELECT ANY DICTIONARY` or `FLASHBACK ANY TABLE` system privilege or the `SELECT_CATALOG_ROLE` role, either granted commonly or granted locally in the root, or the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege granted commonly.
- To create a normal PDB restore point, the current container must be the root and you must have the `SELECT ANY DICTIONARY` or `FLASHBACK ANY TABLE` system privilege, either granted commonly or granted locally in the root, or the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege granted commonly, or the current container must be the PDB for which you want to create the restore point and you must have the `SELECT ANY DICTIONARY`, `FLASHBACK ANY TABLE`, `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege, granted commonly or granted locally in that PDB.
- To create a guaranteed PDB restore point, the current container must be the root and you must have the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege, granted commonly, or the current container must be the PDB for which you want to create

the restore point and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.

- To view a PDB restore point, the current container must be the root and you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege or the SELECT\_CATALOG\_ROLE role, either granted commonly or granted locally in the root, or the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly, or the current container must be the PDB for the restore point and you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.
- To use a PDB restore point, the current container must be the PDB for the restore point and you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.

## Syntax

*create\_restore\_point ::=*

## Semantics

### CLEAN

You can specify CLEAN only when creating a PDB restore point. The PDB must use shared undo and must be closed with no outstanding transactions. Flashing back a PDB using shared undo to a clean PDB restore point does not require restoring backups or creating a clone instance. Therefore, it is faster than flashing back a PDB using shared undo to an SCN or other type of restore point.

### *restore\_point*

Specify the name of the restore point. The name must satisfy the requirements listed in "Database Object Naming Rules".

In a multitenant environment, the CDB and PDBs have their own namespaces for restore points. Therefore, the CDB and each PDB can have a restore point with the same name. When you specify a restore point name in a PDB or for a PDB operation, the name is first interpreted as a PDB restore point for the concerned PDB. If a PDB restore point with the specified name is not found, then it is interpreted as a CDB restore point.

The database can retain at least 2048 normal restore points. In a Multitenant environment, a CDB can retain at least 2048 normal restore points across the entire CDB, including PDB restore points. Normal restore points are retained in the database for at least the number of days specified for the CONTROL\_FILE\_RECORD\_KEEP\_TIME initialization parameter. The default value of that parameter is 7 days. Guaranteed restore points are retained in the database until explicitly dropped by the user.

If you specify neither `PRESERVE` nor `GUARANTEE FLASHBACK DATABASE`, then the resulting restore point enables you to flash the database back to a restore point within the time period determined by the `DB_FLASHBACK_RETENTION_TARGET` initialization parameter. The database automatically manages such restore points. When the maximum number of restore points is reached, according to the rules described in `restore_point` above, the database automatically drops the oldest restore point. Under some circumstances the restore points will be retained in the RMAN recovery catalog for use in restoring long-term backups. You can explicitly drop a restore point using the `DROP RESTORE POINT` statement.

### FOR PLUGGABLE DATABASE

This clause enables you to create a PDB restore point when you are connected to the root. For `pdb_name`, specify the name of the PDB.

If you are connected to the PDB for which you want to create the restore point, then it is not necessary to specify this clause. However, if you specify this clause, then you must specify the name of the PDB to which you are connected.

### AS OF Clause

Use this clause to create a restore point at a specified datetime or SCN in the past. If you specify `TIMESTAMP`, then `expr` must be a valid datetime expression resolving to a time in the past. If you specify `SCN`, then `expr` must be a valid SCN in the database in the past. In either case, `expr` must refer to a datetime or SCN in the current incarnation of the database.

### PRESERVE

Specify `PRESERVE` to indicate that the restore point must be explicitly deleted. Such restore points are useful for preserving a flashback database.

### GUARANTEE FLASHBACK DATABASE

A guaranteed restore point enables you to flash the database back deterministically to the restore point regardless of the `DB_FLASHBACK_RETENTION_TARGET` initialization parameter setting. The guaranteed ability to flash back depends on sufficient space being available in the fast recovery area.

Guaranteed restore points guarantee only that the database will maintain enough flashback logs to flashback the database to the guaranteed restore point. It does not guarantee that the database will have enough undo to flashback any table to the same restore point.

Guaranteed restore points are always preserved. They must be dropped explicitly by the user using the `DROP RESTORE POINT` statement. They do not age out. Guaranteed restore points can use considerable space in the fast recovery area. Therefore, Oracle recommends that you create guaranteed restore points only after careful consideration.

### Examples

#### Creating and Using a Restore Point: Example

The following example creates a normal restore point, updates a table, and then flashes back the altered table to the restore point. The example assumes the user `hr` has the appropriate system privileges to use each of the statements.

```
CREATE RESTORE POINT good_data;

SELECT salary FROM employees WHERE employee_id = 108;
-----  
SALARY  
12000

UPDATE employees SET salary = salary*10
WHERE employee_id = 108;

SELECT salary FROM employees
WHERE employee_id = 108;
-----  
SALARY  
120000

COMMIT;

FLASHBACK TABLE employees TO RESTORE POINT good_data;

SELECT salary FROM employees
WHERE employee_id = 108;
-----  
SALARY  
12000
```

## CREATE ROLE

### Purpose

Use the `CREATE ROLE` statement to create a **role**, which is a set of privileges that can be granted to users or to other roles. You can use roles to administer database privileges. You can add privileges to a role and then grant the role to a user. The user can then enable the role and exercise the privileges granted by the role.

A role contains all privileges granted to the role and all privileges of other roles granted to it. A new role is initially empty. You add privileges to a role with the `GRANT` statement.

If you create a role that is NOT IDENTIFIED or is IDENTIFIED EXTERNALLY or BY *password*, then Oracle Database grants you the role with ADMIN OPTION. However, if you create a role IDENTIFIED GLOBALLY, then the database does not grant you the role. A global role cannot be granted to a user or role directly. Global roles can be granted through EUS enterprise roles, mapped group memberships, and mapped app roles.

**See Also:**

- [GRANT](#) for information on granting roles
- [ALTER USER](#) for information on enabling roles
- [ALTER ROLE](#) and [DROP ROLE](#) for information on modifying or removing a role from the database
- [SET ROLE](#) for information on enabling and disabling roles for the current session
- *Oracle Database Security Guide* for general information about roles
- *Oracle Database Enterprise User Security Administrator's Guide* for details on enterprise roles

**Prerequisites**

You must have the `CREATE ROLE` system privilege.

To specify the `CONTAINER` clause, you must be connected to a multitenant container database (CDB). To specify `CONTAINER = ALL`, the current container must be the root. To specify `CONTAINER = CURRENT`, the current container must be a pluggable database (PDB).

**Syntax**

`create_role ::=`

## Semantics

### *role*

Specify the name of the role to be created. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)". Oracle recommends that the role contain at least one single-byte character regardless of whether the database character set also contains multibyte characters. The maximum length of the role name is 128 bytes. The maximum number of user-defined roles that can be enabled for a single user at one time is 148.

In a non-CDB, a role name cannot begin with C## or c##.

#### Note:

A multitenant container database is the only supported architecture in Oracle Database 21c and later releases. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

In a CDB, the requirements for a role name are as follows:

- The name of a **common role** must begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. By default, the prefix is C##.
- The name of a **local role** must not begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. Regardless of the value of `COMMON_USER_PREFIX`, the name of a local role can never begin with C## or c##.

#### Note:

If the value of `COMMON_USER_PREFIX` is an empty string, then there are no requirements for common or local role names with one exception: the name of a local role can never begin with C## or c##. Oracle recommends against using an empty string value because it might result in conflicts between the names of local and common roles when a PDB is plugged into a different CDB, or when opening a PDB that was closed when a common user was created.

Some roles are defined by SQL scripts provided on your distribution media.

#### See Also:

[GRANT](#) for a list of these predefined roles and [SET ROLE](#) for information on enabling and disabling roles for a user

### NOT IDENTIFIED Clause

Specify NOT IDENTIFIED to indicate that this role is authorized by the database and that no password is required to enable the role.

### IDENTIFIED Clause

Use the IDENTIFIED clause to indicate that a user must be authorized by the specified method before the role is enabled with the SET ROLE statement.

#### BY password

You can create a **local role** with a password with the BY *password* clause. This means that you must specify the password to the database at the time you enable the role.

The password can contain any characters from the database character set except the NULL character (CHR(0)) and the double-quote. The maximum length of the password is 1024 bytes. The password is syntactically an identifier, and may need to be enclosed in double-quotes as required by the "[Database Object Naming Rules](#)". You must ensure that your database, and the clients that need to enable the role are configured to support all the characters comprising the password.

You can enable password-protected roles in a proxy session. Both secure application role and password-protected roles provide a secure method for enabling a role in a session. Oracle recommends using secure password roles instead of password protected roles in instances where the password has to be maintained and transmitted over insecure channels, or if more than one person needs to know the password. Password-protected roles in a proxy session are suitable for situations where automation is used to set the role.

#### USING package

The USING *package* clause lets you create a **secure application role**, which is a role that can be enabled only by applications using an authorized package. If you do not specify *schema*, then the database assumes the package is in your own schema.

#### See Also:

*Oracle Database Security Guide* for information on creating a secure application role

### EXTERNALLY

Specify EXTERNALLY to create an **external role**. An external user must be authorized by an external service, such as an operating system or third-party service, before enabling the role.

Depending on the operating system, the user may have to specify a password to the operating system before the role is enabled.

### GLOBALLY

Specify GLOBALLY to create a **global role**. A global user must be authorized to use the role by the enterprise directory service before the role is enabled at login.

Specify GLOBALLY with AS to map a directory group to a global role when using centrally managed users. The directory group is identified by its domain name.

#### Example: Map a Directory User to a Global User

```
CREATE USER scott_global IDENTIFIED GLOBALLY AS 'cn=scott
taylor,ou=sales,dc=abccorp,dc=com';
```

This effectively maps a directory user named 'scott taylor' in the 'sales' organization unit of the abccorp.com domain to a database global user 'scott\_global'.

You can map an Oracle Database global role to an Azure app role in order to give Azure users and applications additional privileges and roles beyond those that they have through their login schemas.

#### Example: Map an Oracle Database Global Role to an App Role

The example creates a new database global role `widget_sales_role` and maps it to an existing Azure AD application role `WidgetManagerGroup`:

```
CREATE ROLE widget_sales_role IDENTIFIED GLOBALLY AS 'AZURE_ROLE=WidgetManagerGroup';
```

#### See Also:

*Authenticating and Authorizing Microsoft Azure Active Directory Users for Oracle Autonomous Databases*

### CONTAINER Clause

The CONTAINER clause applies when you are connected to a CDB. However, it is not necessary to specify the CONTAINER clause because its default values are the only allowed values.

- To create a common role, you must be connected to the root. You can optionally specify CONTAINER = ALL, which is the default when you are connected to the root.
- To create a local role, you must be connected to a PDB. You can optionally specify CONTAINER = CURRENT, which is the default when you are connected to a PDB.

### Examples

#### Creating a Role: Example

The following statement creates the role `dw_manager`:

```
CREATE ROLE dw_manager;
```

Users who are subsequently granted the `dw_manager` role will inherit all of the privileges that have been granted to this role.

You can add a layer of security to roles by specifying a password, as in the following example:

```
CREATE ROLE dw_manager
  IDENTIFIED BY warehouse;
```

Users who are subsequently granted the `dw_manager` role must specify the password warehouse to enable the role with the `SET ROLE` statement.

The following statement creates global role `warehouse_user`:

```
CREATE ROLE warehouse_user IDENTIFIED GLOBALLY;
```

The following statement creates the same role as an external role:

```
CREATE ROLE warehouse_user IDENTIFIED EXTERNALLY;
```

The following statement creates local role `role1` in the current PDB. The current container must be a PDB when you issue this statement:

```
CREATE ROLE role1 CONTAINER = CURRENT;
```

The following statement creates common role `c##role1`. The current container must be the root when you issue this statement:

```
CREATE ROLE c##role1 CONTAINER = ALL;
```

## CREATE ROLLBACK SEGMENT

### Note:

Oracle strongly recommends that you run your database in automatic undo management mode instead of using rollback segments. Do not use rollback segments unless you must do so for compatibility with earlier versions of Oracle Database. Refer to *Oracle Database Administrator's Guide* for information on automatic undo management.

### Purpose

Use the `CREATE ROLLBACK SEGMENT` statement to create a **rollback segment**, which is an object that Oracle Database uses to store data necessary to reverse, or undo, changes made by transactions.

The information in this section assumes that your database is not running in automatic undo mode (the `UNDO_MANAGEMENT` initialization parameter is set to `MANUAL` or not set at all). If your database is running in automatic undo mode (the `UNDO_MANAGEMENT` initialization parameter is set to `AUTO`, which is the default), then rollback segments are not permitted. However, errors generated in rollback segment operations are suppressed.

Further, if your database has a locally managed `SYSTEM` tablespace, then you cannot create rollback segments in any dictionary-managed tablespace. Instead, you must either use the automatic undo management feature or create locally managed tablespaces to hold the rollback segments.

**Note:**

A tablespace can have multiple rollback segments. Generally, multiple rollback segments improve performance.

- The tablespace must be online for you to add a rollback segment to it.
- When you create a rollback segment, it is initially offline. To make it available for transactions by your Oracle Database instance, bring it online using the `ALTER ROLLBACK SEGMENT` statement. To bring it online automatically whenever you start up the database, add the segment name to the value of the `ROLLBACK_SEGMENT` initialization parameter.

To use objects in a tablespace other than the `SYSTEM` tablespace:

- If you are using rollback segments for undo, then at least one rollback segment (other than the `SYSTEM` rollback segment) must be online.
- If you are running the database in automatic undo mode, then at least one `UNDO` tablespace must be online.

**See Also:**

- [ALTER ROLLBACK SEGMENT](#) for information on altering a rollback segment
- [DROP ROLLBACK SEGMENT](#) for information on removing a rollback segment
- *Oracle Database Reference* for information on the `UNDO_MANAGEMENT` parameter
- *Oracle Database Administrator's Guide* for information on automatic undo mode

**Prerequisites**

To create a rollback segment, you must have the `CREATE ROLLBACK SEGMENT` system privilege.

**Syntax**

`create_rollback_segment ::=`

(`storage_clause`)

## Semantics

### PUBLIC

Specify PUBLIC to indicate that the rollback segment is public and is available to any instance. If you omit this clause, then the rollback segment is private and is available only to the instance naming it in its initialization parameter ROLLBACK\_SEGMENTS.

### *rollback\_segment*

Specify the name of the rollback segment to be created. The name must satisfy the requirements listed in "Database Object Naming Rules".

### TABLESPACE

Use the TABLESPACE clause to identify the tablespace in which the rollback segment is created. If you omit this clause, then the database creates the rollback segment in the SYSTEM tablespace.

#### Note:

Oracle Database must access rollback segments frequently. Therefore, Oracle strongly recommends that you do not create rollback segments in the SYSTEM tablespace, either explicitly or implicitly by omitting this clause. In addition, to avoid high contention for the tablespace containing the rollback segment, it should not contain other objects such as tables and indexes, and it should require minimal extent allocation and deallocation.

To achieve these goals, create rollback segments in locally managed tablespaces with autoallocation disabled—in tablespaces created with the EXTENT MANAGEMENT LOCAL clause with the UNIFORM setting. The AUTOALLOCATE setting is not supported.

#### See Also:

[CREATE TABLESPACE](#)

### *storage\_clause*

The *storage\_clause* lets you specify storage characteristics for the rollback segment.

- The OPTIMAL parameter of the *storage\_clause* is of particular interest, because it applies only to rollback segments.
- You cannot specify the PCTINCREASE parameter of the *storage\_clause* with CREATE ROLLBACK SEGMENT.

 See Also:[storage\\_clause](#)

## Examples

### Creating a Rollback Segment: Example

The following statement creates a rollback segment with default storage values in an appropriately configured tablespace:

```
CREATE TABLESPACE rbs_ts
  DATAFILE 'rbs01.dbf' SIZE 10M
  EXTENT MANAGEMENT LOCAL UNIFORM SIZE 100K;

/* This example and the next will fail if your database is in
   automatic undo mode.
*/
CREATE ROLLBACK SEGMENT rbs_one
  TABLESPACE rbs_ts;
```

The preceding statement is equivalent to the following:

```
CREATE ROLLBACK SEGMENT rbs_one
  TABLESPACE rbs_ts
  STORAGE
  ( INITIAL 10K );
```

# CREATE SCHEMA

## Purpose

Use the `CREATE SCHEMA` statement to create multiple tables and views and perform multiple grants in your own schema in a single transaction.

To execute a `CREATE SCHEMA` statement, Oracle Database executes each included statement. If all statements execute successfully, then the database commits the transaction. If any statement results in an error, then the database rolls back all the statements.

 Note:

This statement does not actually create a schema. Oracle Database automatically creates a schema when you create a user (see [CREATE USER](#)). This statement lets you populate your schema with tables and views and grant privileges on those objects without having to issue multiple SQL statements in multiple transactions.

## Prerequisites

The `CREATE SCHEMA` statement can include `CREATE TABLE`, `CREATE VIEW`, and `GRANT` statements. To issue a `CREATE SCHEMA` statement, you must have the privileges necessary to issue the included statements.

## Syntax

*create\_schema ::=*

## Semantics

### ***schema***

Specify the name of the schema. The schema name must be the same as your Oracle Database username.

### **Restrictions**

While CREATE SCHEMA supports CREATE TABLE , CREATE BLOCKCHAIN TABLE is unsupported.

#### ***create\_table\_statement***

Specify a CREATE TABLE statement to be issued as part of this CREATE SCHEMA statement. Do not end this statement with a semicolon (or other terminator character).

#### See Also:

[CREATE TABLE](#)

#### ***create\_view\_statement***

Specify a CREATE VIEW statement to be issued as part of this CREATE SCHEMA statement. Do not end this statement with a semicolon (or other terminator character).

#### See Also:

[CREATE VIEW](#)

#### ***grant\_statement***

Specify a GRANT statement to be issued as part of this CREATE SCHEMA statement. Do not end this statement with a semicolon (or other terminator character). You can use this clause to grant object privileges on objects you own to other users. You can also grant system privileges to other users if you were granted those privileges WITH ADMIN OPTION.

 See Also:[GRANT](#)

The CREATE SCHEMA statement supports the syntax of these statements only as defined by standard SQL, rather than the complete syntax supported by Oracle Database.

The order in which you list the CREATE TABLE, CREATE VIEW, and GRANT statements is unimportant. The statements within a CREATE SCHEMA statement can reference existing objects or objects you create in other statements within the same CREATE SCHEMA statement.

**Restriction on Granting Privileges to a Schema**

The syntax of the *parallel\_clause* is allowed for a CREATE TABLE statement in CREATE SCHEMA, but parallelism is not used when creating the objects.

 See Also:

The [\*parallel\\_clause\*](#) in the CREATE TABLE documentation

**Examples****Creating a Schema: Example**

The following statement creates a schema named oe for the sample order entry user oe, creates the table new\_product, creates the view new\_product\_view, and grants the SELECT object privilege on new\_product\_view to the sample human resources user hr.

```
CREATE SCHEMA AUTHORIZATION oe
  CREATE TABLE new_product
    (color VARCHAR2(10) PRIMARY KEY, quantity NUMBER)
  CREATE VIEW new_product_view
    AS SELECT color, quantity FROM new_product WHERE color = 'RED'
  GRANT select ON new_product_view TO hr;
```

# SQL Statements: CREATE SEQUENCE to DROP CLUSTER

This chapter contains the following SQL statements:

- [CREATE SEQUENCE](#)
- [CREATE SPFILE](#)
- [CREATE SYNONYM](#)
- [CREATE TABLE](#)
- [CREATE TABLESPACE](#)
- [CREATE TABLESPACE SET](#)
- [CREATE TRIGGER](#)
- [CREATE TYPE](#)
- [CREATE TYPE BODY](#)
- [CREATE USER](#)
- [CREATE VIEW](#)
- [DELETE](#)
- [DISASSOCIATE STATISTICS](#)
- [DROP ANALYTIC VIEW](#)
- [DROP ATTRIBUTE DIMENSION](#)
- [DROP AUDIT POLICY \(Unified Auditing\)](#)
- [DROP CLUSTER](#)

## CREATE SEQUENCE

### Purpose

Use the `CREATE SEQUENCE` statement to create a **sequence**, which is a database object from which multiple users may generate unique integers. You can use sequences to automatically generate primary key values.

When a sequence number is generated, the sequence is incremented, independent of the transaction committing or rolling back. If two users concurrently increment the same sequence, then the sequence numbers each user acquires may have gaps, because sequence numbers are being generated by the other user. One user can never acquire the sequence number generated by another user. After a sequence value is generated by one user, that user can continue to access that value regardless of whether the sequence is incremented by another user.

Sequence numbers are generated independently of tables, so the same sequence can be used for one or for multiple tables. It is possible that individual sequence numbers will appear

to be skipped, because they were generated and used in a transaction that ultimately rolled back. Additionally, a single user may not realize that other users are drawing from the same sequence.

After a sequence is created, you can access its values in SQL statements with the CURRVAL pseudocolumn, which returns the current value of the sequence, or the NEXTVAL pseudocolumn, which increments the sequence and returns the new value.

 **See Also:**

- [Pseudocolumns](#) for more information on using the CURRVAL and NEXTVAL
- ["How to Use Sequence Values"](#) for information on using sequences
- [ALTER SEQUENCE](#) or [DROP SEQUENCE](#) for information on modifying or dropping a sequence

### Prerequisites

To create a sequence in your own schema, you must have the CREATE SEQUENCE system privilege.

To create a sequence in another user's schema, you must have the CREATE ANY SEQUENCE system privilege.

## Syntax

*create\_sequence ::=*

## Semantics

### IF NOT EXISTS

Specifying **IF NOT EXISTS** has the following effects:

- If the sequence does not exist, a new sequence is created at the end of the statement.
- If the sequence exists, this is the sequence you have at the end of the statement. A new one is not created because the older one is detected.

Using IF EXISTS with CREATE results in ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.

### **schema**

Specify the schema to contain the sequence. If you omit *schema*, then Oracle Database creates the sequence in your own schema.

### **sequence**

Specify the name of the sequence to be created. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)".

If you specify none of the clauses INCREMENT BY through GLOBAL, then you create an ascending sequence that starts with 1 and increases by 1 with no upper limit. Specifying only INCREMENT BY -1 creates a descending sequence that starts with -1 and decreases with no lower limit.

- To create a sequence that increments without bound, for ascending sequences, omit the MAXVALUE parameter or specify NOMAXVALUE. For descending sequences, omit the MINVALUE parameter or specify the NOMINVALUE.
- To create a sequence that stops at a predefined limit, for an ascending sequence, specify a value for the MAXVALUE parameter. For a descending sequence, specify a value for the MINVALUE parameter. Also specify NOCYCLE. Any attempt to generate a sequence number once the sequence has reached its limit results in an error.
- To create a sequence that restarts after reaching a predefined limit, specify values for both the MAXVALUE and MINVALUE parameters. Also specify CYCLE.

### **SHARING**

This clause applies only when creating a sequence in an application root. This type of sequence is called an application common object and it can be shared with the application PDBs that belong to the application root. To determine how the sequence is shared, specify one of the following sharing attributes:

- METADATA - A metadata link shares the sequence's metadata, but its data is unique to each container. This type of sequence is referred to as a **metadata-linked application common object**.
- DATA - A data link shares the sequence, and its data is the same for all containers in the application container. Its data is stored only in the application root. This type of sequence is referred to as a **data-linked application common object**.
- NONE - The sequence is not shared.

If you omit this clause, then the database uses the value of the DEFAULT\_SHARING initialization parameter to determine the sharing attribute of the sequence. If the DEFAULT\_SHARING initialization parameter does not have a value, then the default is METADATA.

You cannot change the sharing attribute of a sequence after it is created.

 **See Also:**

- *Oracle Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
- *Oracle Database Administrator's Guide* for complete information on creating application common objects

**INCREMENT BY**

Specify the interval between sequence numbers. This integer value can be any positive or negative integer, but it cannot be 0. This value can have 28 or fewer digits for an ascending sequence and 27 or fewer digits for a descending sequence. The absolute of this value must be less than the difference of `MAXVALUE` and `MINVALUE`. If this value is negative, then the sequence descends. If the value is positive, then the sequence ascends. If you omit this clause, then the interval defaults to 1.

**START WITH**

Specify the first sequence number to be generated. Use this clause to start an ascending sequence at a value greater than its minimum or to start a descending sequence at a value less than its maximum. For ascending sequences, the default value is the minimum value of the sequence. For descending sequences, the default value is the maximum value of the sequence. This integer value can have 28 or fewer digits for positive values and 27 or fewer digits for negative values.

 **Note:**

This value is not necessarily the value to which an ascending or descending cycling sequence cycles after reaching its maximum or minimum value, respectively.

**MAXVALUE**

Specify the maximum value the sequence can generate. This integer value can have 28 or fewer digits for positive values and 27 or fewer digits for negative values. `MAXVALUE` must be equal to or greater than `START WITH` and must be greater than `MINVALUE`.

**NOMAXVALUE**

Specify `NOMAXVALUE` to indicate a maximum value of  $10^{28}-1$  for an ascending sequence or -1 for a descending sequence. This is the default.

**MINVALUE**

Specify the minimum value of the sequence. This integer value can have 28 or fewer digits for positive values and 27 or fewer digits for negative values. `MINVALUE` must be less than or equal to `START WITH` and must be less than `MAXVALUE`.

**NOMINVALUE**

Specify `NOMINVALUE` to indicate a minimum value of 1 for an ascending sequence or  $-(10^{27}-1)$  for a descending sequence. This is the default.

## CYCLE

Specify CYCLE to indicate that the sequence continues to generate values after reaching either its maximum or minimum value. After an ascending sequence reaches its maximum value, it generates its minimum value. After a descending sequence reaches its minimum, it generates its maximum value.

## NOCYCLE

Specify NOCYCLE to indicate that the sequence cannot generate more values after reaching its maximum or minimum value. This is the default.

## CACHE

Specify how many values of the sequence the database preallocates and keeps in memory for faster access. This integer value can have 28 or fewer digits. The minimum value for this parameter is 2. For sequences that cycle, this value must be less than the number of values in the cycle. You cannot cache more values than will fit in a given cycle of sequence numbers. Therefore, the maximum value allowed for CACHE must be less than the value determined by the following formula:

```
CEIL ( (MAXVALUE - MINVALUE) / ABS (INCREMENT) )
```

If a system failure occurs, then all cached sequence values that have not been used in committed DML statements are lost. The potential number of lost values is equal to the value of the CACHE parameter.

### Note:

Oracle recommends using the CACHE setting to enhance performance if you are using sequences in an Oracle Real Application Clusters environment.

## NOCACHE

Specify NOCACHE to indicate that values of the sequence are not preallocated. If you omit both CACHE and NOCACHE, then the database caches 20 sequence numbers by default.

## ORDER

Specify ORDER to guarantee that sequence numbers are generated in order of request. This clause is useful if you are using the sequence numbers as timestamps. Guaranteeing order is usually not important for sequences used to generate primary keys.

## NOORDER

Specify NOORDER if you do not want to guarantee sequence numbers are generated in order of request. This is the default.

## KEEP

Specify KEEP if you want NEXTVAL to retain its original value during replay for Application Continuity. This behavior will occur only if the user running the application

is the owner of the schema containing the sequence. This clause is useful for providing bind variable consistency at replay after recoverable errors. Refer to *Oracle Database Development Guide* for more information on Application Continuity.

#### NOKEEP

Specify `NOKEEP` if you do not want `NEXTVAL` to retain its original value during replay for Application Continuity. This is the default.

#### Note:

The `KEEP` and `NOKEEP` clauses apply only to the owner of the schema containing the sequence. You can control whether `NEXTVAL` retains its original value for other users during replay for Application Continuity by granting or revoking the `KEEP SEQUENCE` object privilege on the sequence. Refer to [Table 18-2](#) for more information on the `KEEP SEQUENCE` object privilege.

#### SCALE

Use `SCALE` to enable sequence scalability. When `SCALE` is specified, a numeric offset is affixed to the beginning of the sequence which removes all duplicates in generated values.

#### EXTEND

If you specify `EXTEND` with `SCALE` the generated sequence values are all of length  $(x+y)$ , where  $x$  is the length of the scalable offset (default value is 6), and  $y$  is the maximum number of digits in the sequence (`maxvalue/minvalue`).

When you use `SCALE` it is highly recommended that you not use `ORDER` simultaneously on the sequence.

#### NOEXTEND

`NOEXTEND` is the default setting for the `SCALE` clause. With the `NOEXTEND` setting, the generated sequence values are at most as wide as the maximum number of digits in the sequence (`maxvalue/minvalue`). This setting is useful for integration with existing applications where sequences are used to populate fixed width columns.

#### NOSCALE

Use `NOSCALE` to disable sequence scalability.

#### SHARD

For complete semantics on the `SHARD` clause please refer to the `SHARD` clause of the [ALTER SEQUENCE](#) statement.

#### SESSION

Specify `SESSION` to create a session sequence, which is a special type of sequence that is specifically designed to be used with global temporary tables that have session visibility. Unlike the existing regular sequences (referred to as "global" sequences for the sake of comparison), a session sequence returns a unique range of sequence numbers only within a session, but not across sessions. Another difference is that session sequences are not

persistent. If a session goes away, so does the state of the session sequences that were accessed during the session.

Session sequences must be created by a read-write database but can be accessed on any read-write or read-only databases (either a regular database temporarily open read-only or a standby database).

The CACHE, NOCACHE, ORDER, or NOORDER clauses are ignored when specified with the SESSION clause.

#### See Also:

*Oracle Data Guard Concepts and Administration* for more information on session sequences

### GLOBAL

Specify GLOBAL to create a global, or regular, sequence. This is the default.

#### Examples

##### Creating a Sequence: Example

The following statement creates the sequence `customers_seq` in the sample schema `oe`. This sequence could be used to provide customer ID numbers when rows are added to the `customers` table.

```
CREATE SEQUENCE customers_seq
  START WITH    1000
  INCREMENT BY  1
  NOCACHE
  NOCYCLE;
```

The first reference to `customers_seq.nextval` returns 1000. The second returns 1001. Each subsequent reference will return a value 1 greater than the previous reference.

## CREATE SPFILE

#### Purpose

Use the `CREATE SPFILE` statement to create a server parameter file either from a traditional plain-text initialization parameter file or from the current system-wide settings. Server parameter files are binary files that exist only on the server and are called from client locations to start up the database.

Server parameter files let you make persistent changes to individual parameters. When you use a server parameter file, you can specify in an `ALTER SYSTEM SET parameter` statement that the new parameter value should be persistent. This means that the new value applies not only in the current instance, but also to any instances that are started up subsequently. Traditional plain-text parameter files do not let you make persistent changes to parameter values.

Server parameter files are located on the server, so they allow for automatic database tuning by Oracle Database and for backup by Recovery Manager (RMAN).

To use a server parameter file when starting up the database, you must create it using the `CREATE SPFILE` statement.

All instances in an Oracle Real Application Clusters environment must use the same server parameter file. However, when otherwise permitted, individual instances can have different settings of the same parameter within this one file. Instance-specific parameter definitions are specified as `SID.parameter = value`, where `SID` is the instance identifier.

The method of starting up the database with a server parameter file depends on whether you create a default or nondefault server parameter file. Refer to "[Creating a Server Parameter File: Examples](#)" for examples of how to use server parameter files.

#### Note on Creating Server Parameter Files in a CDB

When you create a server parameter file in a multitenant container database (CDB), the current container can be the root or a PDB.

- If the current container is the root, then the values that you set for initialization parameters in the root are used as default values for all other containers.
- If the current container is a PDB, then the database stores the PDB's initialization parameter values internally, rather than in a file. Therefore, you cannot specify an `spfile_name`. The values that you set for initialization parameters in the PDB are persistent and override any values set for those parameters in the root.

You can subsequently use the `ALTER SYSTEM` statement to modify initialization parameter values for the root or a PDB.

#### See Also:

- [CREATE PFILE](#) for information on creating a regular text parameter file from a binary server parameter file
- *Oracle Database Administrator's Guide* for information on traditional plain-text initialization parameter files and server parameter files
- *Oracle Real Application Clusters Administration and Deployment Guide* for information on using server parameter files in an Oracle Real Application Clusters environment

#### Prerequisites

You must have the `SYSBACKUP`, `SYSDBA`, `SYSDG`, or `SYSOPER` system privilege to execute this statement. You can execute this statement before or after instance startup. However, if you have already started an instance using `spfile_name`, you cannot specify the same `spfile_name` in this statement.

To create a server parameter file in a CDB, the current container must be the root and you must have the commonly granted `SYSBACKUP`, `SYSDBA`, `SYSDG`, or `SYSOPER` system privilege.

## Syntax

***create\_spfile::=***

## Semantics

### *spfile\_name*

This clause lets you specify a name for the server parameter file you are creating.

If you specify *spfile\_name*, then Oracle Database creates a nondefault server parameter file.

- For *spfile\_name*, you can specify a traditional filename, a file in an Oracle ACFS (Oracle Advanced Cluster File System) file system, or an Oracle Storage Management (Oracle ASM) filename.
- If you specify a traditional filename or a file in an Oracle ACFS file system, then *spfile\_name* can include a path prefix. If you do not specify such a path prefix, then the database adds the path prefix for the default storage location, which is platform dependent.
- If you specify the Oracle ASM filename syntax, then the database creates the spfile in an Oracle ASM disk group.
- When using a nondefault server parameter file, you must specify the server parameter filename in the `STARTUP` command when you start up the database. The exception to this rule is as follows:
  - If the database is defined as a resource in Oracle Clusterware, the instance from which the command is issued is running, and you specify the *spfile\_name*, specify the `FROM PFILE` clause, and omit the `AS COPY` clause, then this statement automatically updates the SPFILE in the database resource. In this case, you can start up the database without referring to the server parameter file by name. If the instance from which the command is issued is *not* running, then the SPFILE in the database resource must be updated manually using `srvctl modify database -d dbname -spfile spfile_path`.

If you omit *spfile\_name*, then Oracle Database uses the platform-specific default server parameter filename. If such a file already exists on the server, then this statement overwrites it. When using a default server parameter file, you can start up the database without referring to the file by name.

### Restriction on *spfile\_name*

You cannot specify *spfile\_name* when creating a server parameter file while connected to a PDB.

 See Also:

- "[Creating a Server Parameter File: Examples](#)" for information on starting up the database with default and nondefault server parameter files
- [\*file\\_specification\*](#) for the syntax of traditional and Oracle ASM filenames and [\*ALTER DISKGROUP\*](#) for information on modifying the characteristics of an Oracle ASM file
- The appropriate operating-system-specific documentation for default parameter file names

***pfile\_name***

Specify the traditional plain-text initialization parameter file from which you want to create a server parameter file. The traditional parameter file must reside on the server.

- If you specify *pfile\_name* and the traditional parameter file does not reside in the default directory for parameter files on your operating system, then you must specify the full path.
- If you do not specify *pfile\_name*, then Oracle Database looks in the default directory for parameter files on your operating system for the default parameter filename and uses that file. If that file does not exist in the expected directory, then the database returns an error.

 Note:

In an Oracle Real Application Clusters environment, you must first combine all instance parameter files into one file before specifying that filename in this statement to create a server parameter file. For information on accomplishing this step, see *Oracle Real Application Clusters Administration and Deployment Guide*.

**AS COPY**

This clause applies only if the database is defined as a resource in Oracle Clusterware. By default, if you specify both the *spfile\_name* and the *FROM PFILE* clause, then the *CREATE SPFILE* statement automatically updates the SPFILE in the database resource. You can specify *AS COPY* to prevent the database from updating the SPFILE in the database resource.

**MEMORY**

Specify *MEMORY* to create an spfile using the current system-wide parameter settings. In an Oracle RAC environment, the created file will contain the parameter settings from each instance.

**Examples****[Creating a Server Parameter File: Examples](#)**

The following example creates a default server parameter file from a traditional plain-text parameter file named *t\_init1.ora*:

```
CREATE SPFILE
  FROM PFILE = '$ORACLE_HOME/work/t_init1.ora';
```

 **Note:**

Typically you will need to specify the full path and filename for parameter files on your operating system.

When you create a default server parameter file, you subsequently start up the database using that server parameter file by using the SQL\*Plus command `STARTUP` without the `PFILE` parameter, as follows:

```
STARTUP
```

The following example creates a nondefault server parameter file `s_params.ora` from a traditional plain-text parameter file named `t_init1.ora`:

```
CREATE SPFILE = 's_params.ora'
  FROM PFILE = '$ORACLE_HOME/work/t_init1.ora';
```

When you create a nondefault server parameter file, you subsequently start up the database by first creating a traditional parameter file containing the following single line:

```
spfile = 's_params.ora'
```

The name of this parameter file must comply with the naming conventions of your operating system. You then use the single-line parameter file in the `STARTUP` command. The following example shows how to start up the database, assuming that the single-line parameter file is named `new_param.ora`:

```
STARTUP PFILE=new_param.ora
```

## CREATE SYNONYM

### Purpose

Use the `CREATE SYNONYM` statement to create a **synonym**, which is an alternative name for a table, view, sequence, operator, procedure, stored function, package, materialized view, Java class schema object, user-defined object type, or another synonym. A synonym places a dependency on its target object and becomes invalid if the target object is changed or dropped.

Synonyms provide both data independence and location transparency. Synonyms permit applications to function without modification regardless of which user owns the table or view and regardless of which database holds the table or view. However, synonyms are not a substitute for privileges on database objects. Appropriate privileges must be granted to a user before the user can use the synonym.

You can refer to synonyms in the following DML statements: `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `FLASHBACK TABLE`, `EXPLAIN PLAN`, `LOCK TABLE`, `MERGE`, and `CALL`.

You can refer to synonyms in the following DDL statements: `AUDIT`, `NOAUDIT`, `GRANT`, `REVOKE`, and `COMMENT`.

**See Also:**

*Oracle Database Concepts* for general information on synonyms

**Prerequisites**

To create a private synonym in your own schema, you must have the `CREATE SYNONYM` system privilege.

To create a private synonym in another user's schema, you must have the `CREATE ANY SYNONYM` system privilege.

To create a `PUBLIC` synonym, you must have the `CREATE PUBLIC SYNONYM` system privilege.

**Syntax**

`create_synonym::=`

**Semantics****OR REPLACE**

Specify `OR REPLACE` to re-create the synonym if it already exists. Use this clause to change the definition of an existing synonym without first dropping it.

**Restriction on Replacing a Synonym**

You cannot use the `OR REPLACE` clause for a type synonym that has any dependent tables or dependent valid user-defined object types.

**IF NOT EXISTS**

Specifying `IF NOT EXISTS` has the following effects:

- If the synonym does not exist, a new synonym is created at the end of the statement.
- If the synonym exists, this is the synonym you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error:  
`ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

## [ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the synonym is an editioned or noneditioned object if editioning is enabled for the schema object type `SYNONYM` in *schema*. For private synonyms, the default is `EDITIONABLE`. For public synonyms, the default is `NONEDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

## PUBLIC

Specify `PUBLIC` to create a public synonym. Public synonyms are accessible to all users. However each user must have appropriate privileges on the underlying object in order to use the synonym.

When resolving references to an object, Oracle Database uses a public synonym only if the object is not prefaced by a schema and is not followed by a database link.

If you omit this clause, then the synonym is private. A private synonym name must be unique in its schema. A private synonym is accessible to users other than the owner only if those users have appropriate privileges on the underlying database object and specify the schema along with the synonym name.

### Notes on Public Synonyms

The following notes apply to public synonyms:

- If you create a public synonym and it subsequently has dependent tables or dependent valid user-defined object types, then you cannot create another database object of the same name as the synonym in the same schema as the dependent objects.
- Take care not to create a public synonym with the same name as an existing schema. If you do so, then all PL/SQL units that use that name will be invalidated.

## *schema*

Specify the schema to contain the synonym. If you omit *schema*, then Oracle Database creates the synonym in your own schema. You cannot specify a schema for the synonym if you have specified `PUBLIC`.

## *synonym*

Specify the name of the synonym to be created. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)".

 **Note:**

The maximum length of a synonym name is subject to the following rules:

- If the `COMPATIBLE` initialization parameter is set to a value of 12.2 or higher, then the maximum length of a synonym name is 128 bytes. The database will allow you to create and drop synonyms of length 129 to 4000 bytes. However, unless these longer synonym names represent a Java name they will not work in any other SQL command.
- If the `COMPATIBLE` initialization parameter is set to a value lower than 12.2, then the maximum length of a synonym name is 30 bytes. The database will allow you to create and drop synonyms of length 31 to 128 bytes. However, unless these longer synonym names represent a Java name they will not work in any other SQL command.

The longer synonym names are transformed into obscure shorter strings for storage in the data dictionary.

 **See Also:**

["CREATE SYNONYM: Examples"](#) and ["Oracle Database Resolution of Synonyms: Example"](#)

## SHARING

This clause applies only when creating a synonym in an application root. This type of synonym is called an application common object and it can be shared with the application PDBs that belong to the application root. To determine how the synonym is shared, specify one of the following sharing attributes:

- **METADATA** - A metadata link shares the synonym's metadata, but its data is unique to each container. This type of synonym is referred to as a **metadata-linked application common object**.
- **NONE** - The synonym is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the synonym. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is **METADATA**.

You cannot change the sharing attribute of a synonym after it is created.

 **See Also:**

- *Oracle Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
- *Oracle Database Administrator's Guide* for complete information on creating application common objects

## FOR Clause

Specify the object for which the synonym is created. The schema object for which you are creating the synonym can be of the following types:

- Table or object table
- View or object view
- Sequence
- Stored procedure, function, or package
- Materialized view
- Java class schema object
- User-defined object type
- Synonym

The schema object need not currently exist and you need not have privileges to access the object.

### Restriction on the FOR Clause

The schema object cannot be contained in a package.

## ***schema***

Specify the schema in which the object resides. If you do not qualify object with *schema*, then the database assumes that the schema object is in your own schema.

If you are creating a synonym for a procedure or function on a remote database, then you must specify *schema* in this CREATE statement. Alternatively, you can create a local public synonym on the database where the object resides. However, the database link must then be included in all subsequent calls to the procedure or function.

## ***dblink***

You can specify a complete or partial database link to create a synonym for a schema object on a remote database where the object is located. If you specify *dblink* and omit *schema*, then the synonym refers to an object in the schema specified by the database link. Oracle recommends that you specify the schema containing the object in the remote database.

If you omit *dblink*, then Oracle Database assumes the object is located on the local database.

### Restriction on Database Links

You cannot specify *dblink* for a Java class synonym.

 See Also:

- ["References to Objects in Remote Databases"](#) for more information on referring to database links
- [CREATE DATABASE LINK](#) for more information on creating database links

## Examples

### CREATE SYNONYM: Examples

To define the synonym `offices` for the table `locations` in the schema `hr`, issue the following statement:

```
CREATE SYNONYM offices
  FOR hr.locations;
```

To create a PUBLIC synonym for the `employees` table in the schema `hr` on the remote database, you could issue the following statement:

```
CREATE PUBLIC SYNONYM emp_table
  FOR hr.employees@remote.us.example.com;
```

A synonym may have the same name as the underlying object, provided the underlying object is contained in another schema.

### Oracle Database Resolution of Synonyms: Example

Oracle Database attempts to resolve references to objects at the schema level before resolving them at the PUBLIC synonym level. For example, the schemas `oe` and `sh` both contain tables named `customers`. In the next example, user `SYSTEM` creates a PUBLIC synonym named `customers` for `oe.customers`:

```
CREATE PUBLIC SYNONYM customers FOR oe.customers;
```

If the user `sh` then issues the following statement, then the database returns the count of rows from `sh.customers`:

```
SELECT COUNT(*) FROM customers;
```

To retrieve the count of rows from `oe.customers`, the user `sh` must preface `customers` with the schema name. (The user `sh` must have select permission on `oe.customers` as well.)

```
SELECT COUNT(*) FROM oe.customers;
```

If the user `hr`'s schema does not contain an object named `customers`, and if `hr` has select permission on `oe.customers`, then `hr` can access the `customers` table in `oe`'s schema by using the public synonym `customers`:

```
SELECT COUNT(*) FROM customers;
```

# CREATE TABLE

## Purpose

Use the `CREATE TABLE` statement to create one of the following types of tables:

- A **relational table**, which is the basic structure to hold user data.
- An **object table**, which is a table that uses an object type for a column definition. An object table is explicitly defined to hold object instances of a particular type.

You can also create an object type and then use it in a column when creating a relational table.

Tables are created with no data unless a subquery is specified. You can add rows to a table with the `INSERT` statement. After creating a table, you can define additional columns, partitions, and integrity constraints with the `ADD` clause of the `ALTER TABLE` statement. You can change the definition of an existing column or partition with the `MODIFY` clause of the `ALTER TABLE` statement.

#### See Also:

- *Oracle Database Administrator's Guide* and [CREATE TYPE](#) for more information about creating objects
- [ALTER TABLE](#) and [DROP TABLE](#) for information on modifying and dropping tables

#### Prerequisites

To create a **relational table** in your own schema, you must have the `CREATE TABLE` system privilege. To create a table in another user's schema, you must have the `CREATE ANY TABLE` system privilege. Also, the owner of the schema to contain the table must have either space quota on the tablespace to contain the table or the `UNLIMITED TABLESPACE` system privilege.

In addition to these table privileges, to create an object table or a relational table with an object type column, the owner of the table must have the `EXECUTE` object privilege in order to access all types referenced by the table, or you must have the `EXECUTE ANY TYPE` system privilege. These privileges must be granted explicitly and not acquired through a role.

Additionally, if the table owner intends to grant access to the table to other users, then the owner must have been granted the `EXECUTE` object privilege on the referenced types `WITH GRANT OPTION`, or have the `EXECUTE ANY TYPE` system privilege `WITH ADMIN OPTION`. Without these privileges, the table owner has insufficient privileges to grant access to the table to other users.

To enable a unique or primary key constraint, you must have the privileges necessary to create an index on the table. You need these privileges because Oracle Database creates an index on the columns of the unique or primary key in the schema containing the table.

To specify an edition in the `evaluation_edition_clause` or the `unusable_editions_clause`, you must have the `USE` privilege on the edition.

To specify the `zonemap_clause`, you must have the permissions necessary to create a zone map. Refer to the "Prerequisites" section in the documentation on `CREATE MATERIALIZED ZONEMAP`.

To create an **external table**, you must have the required read and write operating system privileges on the appropriate operating system directories. You must have the `READ` object privilege on the database directory object corresponding to the operating system directory in which the external data resides. You must also have the `WRITE` object privilege on the database directory in which the files will reside if you specify a log file or bad file in the `opaque_format_spec` or if you unload data into an external table from a database table by specifying the `AS subquery` clause.

To create an **XMLType table** in a different database schema from your own, you must have not only privilege `CREATE ANY TABLE` but also privilege `CREATE ANY INDEX`. This is because a unique index is created on column `OBJECT_ID` when you create the table. Column `OBJECT_ID` stores a system-generated object identifier.

 **See Also:**

- [CREATE INDEX](#)
- *Oracle Database Administrator's Guide* for more information about the privileges required to create tables using types

## Syntax

*create\_table*::=

(*relational\_table*::=, *object\_table*::=, *XMLType\_table*::= )

*relational table*::=

 **Note:**

Each of the clauses following the table name is optional for any given relational table. However, for every table you must at least specify either column names and data types using the *relational\_properties* clause or an AS *subquery* clause using the *table\_properties* clause.

### **Semantics**

#### **GLOBAL TEMPORARY**

Specify `GLOBAL TEMPORARY` to create a temporary table, whose **definition** is visible to all sessions with appropriate privileges. The **data** in a temporary table is visible only to the session that inserts the data into the table.

When you first create a temporary table, its metadata is stored in the data dictionary, but no space is allocated for table data. Space is allocated for the table segment at the time of the first DML operation on the table. The temporary table definition persists in the same way as the definitions of regular tables, but the table segment and any data the table contains are either **session-specific** or **transaction-specific** data. You specify whether the table segment and data are session- or transaction-specific with the `ON COMMIT` clause.

You can perform DDL operations (such as `ALTER TABLE`, `DROP TABLE`, `CREATE INDEX`) on a temporary table only when no session is bound to it. A session becomes bound to a

temporary table with an `INSERT` operation on the table. A session becomes unbound to a temporary table with a `TRUNCATE` statement or at session termination, or, for a transaction-specific temporary table, by issuing a `COMMIT` or `ROLLBACK` statement.

### PRIVATE TEMPORARY

Specify `PRIVATE TEMPORARY` to create a private temporary table.

A private temporary table differs from a temporary table in that its **definition** and **data** are visible **only** within the session that created it. Use the `ON COMMIT` clause to define the scope of a private temporary table: either **transaction** or **session**. The `ON COMMIT` clause used with the keywords `DROP DEFINITION` creates a transaction-specific table whose data **and** definition are dropped when the transaction commits. This is the default behavior. The `ON COMMIT` clause used with keywords `PRESERVE DEFINITION` creates a session-specific table whose definition is preserved when the transaction commits. See here for usage details of the `ON COMMIT` clause.

Three DDL statements are supported for private temporary tables: `CREATE`, `DROP`, and `TRUNCATE`.

### Restrictions on Temporary Tables

Temporary tables are subject to the following restrictions:

- Temporary tables cannot be partitioned, clustered, or index organized.
- You cannot specify any foreign key constraints on temporary tables.
- Temporary tables cannot contain columns of nested table.
- You cannot specify the following clauses of the `LOB storage clause`: `TABLESPACE`, `storage clause`, or `logging clause`.
- Parallel `UPDATE`, `DELETE` and `MERGE` are not supported for temporary tables.
- The only part of the `segment_attributes_clause` you can specify for a temporary table is `TABLESPACE`, which allows you to specify a single temporary tablespace.
- Distributed transactions are not supported for temporary tables.
- A temporary table cannot contain `INVISIBLE` columns.

### Restrictions on Private Temporary Tables

In addition to the general limitations of temporary tables, private temporary tables are subject to the following restrictions:

You must be a user other than `SYS` to create private temporary tables.

You cannot specify the following constraints on private temporary tables that are permitted on global temporary tables:

- `PRIMARY KEY` constraint
- `UNIQUE` constraint
- `CHECK` constraint
- `NOT NULL` constraint
- The name of private temporary tables must *always* be prefixed with whatever is defined with the `init.ora` parameter `PRIVATE_TEMP_TABLE_PREFIX`. The default is `ORA$PTT_`.

- You cannot create indexes, materialized views, or zone maps on private temporary tables.
- You cannot define column with default values.
- You cannot reference private temporary tables in any permanent object, e.g. views or triggers.
- Private temporary tables are not visible through database links.
- You cannot associate table columns of private temporary tables with a domain using CREATE TABLE. Doing so results in the following error: Cannot associate a private temporary table with a domain.

 **See Also:**

*Oracle Database Concepts* for information on temporary tables and "[Creating a Table: Temporary Table Example](#)"

## SHARDED

Specify SHARDED to create a sharded table.

This clause is valid only if you are using Oracle Sharding, which is a data tier architecture in which data is horizontally partitioned across independent databases. Each database in such configuration is called a shard. All of the shards together make up a single logical database, which is referred to as a sharded database (SDB). Horizontal partitioning involves splitting a table across shards so that each shard contains the table with the same columns but a different subset of rows. A table split up in this manner is called a sharded table.

When you create a sharded table, you must specify a tablespace set in which to create the table. There is no default tablespace set for sharded tables. See [CREATE TABLESPACE SET](#) for more information.

Oracle Sharding is based on the Oracle Partitioning feature. Therefore, a sharded table must be a partitioned or composite-partitioned table. When creating a sharded table, you must specify one of the *table\_partitioning\_clauses*. See [table\\_partitioning\\_clauses](#) for the full semantics of these clauses.

### Restrictions on Sharded Tables

The following restrictions apply to sharded tables:

- In system-managed sharding you can create multiple root tables (and therefore table families) without throwing ORA-02530 , when the CREATE SHARDED TABLE statement does not contain a PARTITION BY REFERENCE or PARENT clause and there is already a root table in existence.
- A sharded table cannot be a temporary table or an index-organized table.
- A sharded table cannot contain a nested table column or an identity column.
- You cannot specify a tablespace for a sharded system or a composite sharded table with the TABLESPACE clause, because system or composite sharded tables require tablespace sets.
- You cannot create tablespace sets in a user-defined sharding environment.

- A sharded tablespace is required for sharded tables. Normal tablespaces are not supported.
- You cannot specify the same tablespace for multiple partitions of the sharded table. This rule applies to subpartitions also. The same tablespace cannot be specified for subpartitions belonging to different partitions of a sharded table.
- You must specify a tablespace per partition of non-reference partitioned sharded tables.
- For user defined sharding the partition method must be range or list. Autolist and Interval partitioning is not supported.
- The list partition method can only have one partitioning column.
- Default partitions are not supported in list partitioned tables.
- NULL partitions are not supported in list partitioned tables.
- A primary key constraint defined on a sharded table must contain the sharding columns. A foreign key constraint on a column of a sharded table referencing a duplicated table column is not supported.
- System partitioning and interval-range partitioning are not supported for sharded tables.
- You cannot specify a virtual column in a sharded table in the PARTITION BY or PARTITIONSET BY clauses.
- XMLType columns for sharded tables are defaulted to TRANSPORTABLE BINARY XML, which is the only storage type allowed. Any other storage clause for XMLType will throw an error.

 **See Also:**

- *Using Oracle Sharding*
- *Oracle Database Administrator's Guide*

## DUPLICATED

This clause is valid only if you are using Oracle Sharding. Specify DUPLICATED to create a duplicated table, which is duplicated on all shards. It can be a nonpartitioned table or partitioned table.

Duplicated tables are not tied to any table family.

### Restrictions on Duplicated Tables

The following restrictions apply to duplicated tables:

- A duplicated table cannot contain a LONG column.
- The maximum number of non-primary key columns in a duplicated table is 999.
- XMLType columns for duplicated tables are defaulted to TRANSPORTABLE BINARY XML, which is the only storage type allowed. Any other storage clause for XMLType will throw an error.
- A duplicated table cannot be a temporary table.

- A duplicated table cannot be a reference-partitioned table or a system-partitioned table.
- You cannot specify NOLOGGING or PARALLEL for a duplicated table.
- You cannot enable a duplicated table for the In-Memory Column Store.

### IMMUTABLE

Specify the IMMUTABLE keyword to create an append-only table that protects data from unauthorized modification by insiders.

You can create a blockchain table that emphasizes its immutability by using the keywords IMMUTABLE BLOCKCHAIN in CREATE TABLE.

You must specify the mandatory *immutable\_table\_clauses* when you create an immutable table using the CREATE IMMUTABLE TABLE statement.

### Prerequisites

- The COMPATIBLE initialization parameter must be set to 19.11.0.0 or higher.
- The CREATE TABLE system privilege is required to create immutable tables in your own schema. The CREATE ANY TABLE system privilege is required to create immutable tables in another user's schema.
- The NO DROP and NO DELETE clauses are mandatory.

### BLOCKCHAIN

Specify the BLOCKCHAIN keyword to create a blockchain table.

You must specify the mandatory *blockchain\_table\_clauses* when you create a blockchain table using the CREATE BLOCKCHAIN TABLE statement.

When you create a blockchain table, an entry is created in the dictionary table `blockchain_table$` owned by `SYS`.

### Restrictions

The following CREATE TABLE clauses are disallowed with the creation of blockchain tables:

- ORGANIZATION INDEX
- ORGANIZATION EXTERNAL
- NESTED TABLE

#### See Also:

- *Managing Immutable Tables*
- *Managing Blockchain Tables*

### IF NOT EXISTS

Specifying IF NOT EXISTS has the following effects:

- If the table does not exist, a new table is created at the end of the statement.

- If the table exists, this is the table you have at the end of the statement. A new one is not created because the older table is detected.

Using `IF EXISTS` with `CREATE TABLE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

### ***schema***

Specify the schema to contain the table. If you omit `schema`, then the database creates the table in your own schema.

### ***table***

Specify the name of the table or object table to be created. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)".

#### **See Also:**

*Oracle Database Administrator's Guide* for more on sharded tables.

## **SHARING**

This clause applies only when creating a table in an application root. This type of table is called an application common object and its data can be shared with the application PDBs that belong to the application root. To determine how the table data is shared, specify one of the following sharing attributes:

- **METADATA** - A metadata link shares the table's metadata, but its data is unique to each container. This type of table is referred to as a **metadata-linked application common object**.
- **DATA** - A data link shares the table, and its data is the same for all containers in the application container. Its data is stored only in the application root. This type of table is referred to as a **data-linked application common object**.
- **EXTENDED DATA** - An extended data link shares the table, and its data in the application root is the same for all containers in the application container. However, each application PDB in the application container can store data that is unique to the application PDB. For this type of table, data is stored in the application root and, optionally, in each application PDB. This type of table is referred to as an **extended data-linked application common object**.
- **NONE** - The table is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the table. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is `METADATA`.

When creating a relational table, you can specify `METADATA`, `DATA`, `EXTENDED DATA`, or `NONE`.

When creating an object table or an `XMLTYPE` table, you can specify only `METADATA` or `NONE`.

You cannot change the sharing attribute of a table after it is created.

#### See Also:

- *Oracle Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
- *Oracle Database Administrator's Guide* for complete information on creating application common objects

#### ***relational\_table***

This clause lets you create a relational table.

#### ***relational\_properties***

The relational properties describe the components of a relational table.

#### ***column\_definition***

The `column_definition` lets you define the characteristics of the column.

##### **Specifying *column\_definition* with AS subquery**

If you specify the `AS subquery` clause, and each column returned by `subquery` has a column name or is an expression with a specified column alias, then you can omit the `column_definition` clause. In this case, the names of the columns of table are the same as the names of the columns returned by `subquery`. The exception is creating an index-organized table, for which you must specify the `column_definition` clause, because you must designate a primary key column. Regardless of the table type, if you specify the `column_definition` clause and the `AS subquery` clause, then you must omit `datatype` from the `column_definition` clause.

#### ***column***

Specify the name of a column of the table. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)".

If you also specify `AS subquery`, then you can omit `column` and `datatype` unless you are creating an index-organized table. If you specify `AS subquery` when creating an index-organized table, then you must specify `column`, and you must omit `datatype`.

The absolute maximum number of columns in a table is 1000, if the `MAX_COLUMNS` initialization parameter = `STANDARD`, or 4096 columns if `MAX_COLUMNS` = `EXTENDED`. See *Oracle Database Reference* for more on the `MAX_COLUMNS` initialization parameter.

When you create an object table or a relational table with columns of object, nested table, varray, or REF type, Oracle Database maps the columns of the user-defined types to relational columns, in effect creating hidden columns that count toward the 1000-column limit. A relational column that stores a user-defined type attribute inherits the collation property of the attribute. In Oracle Database 12c Release 2 (12.2), user-defined types are created using the pseudo-collation property `USING_NLS_COMP` and their corresponding relational columns inherit this property.

***domain\_datatype******domain\_clause***

Use this clause to associate columns with a domain. You can associate non-strict domains with a table column with a compatible type with any limit. For example, a number(10) domain can be assigned to columns with number(9) or number(11). For strict domains you can only associate their columns with table columns with a compatible type and identical type limits. For example, a number(10) domain column can only be assigned to numeric columns with precision 10, like decimal(10) or numeric(10).

The position of columns in this clause is the same as those in the domain. The number of columns listed must be the same as in *domain\_name*.

Each column can belong to at most one domain. If a column is in two or more domains, the statement will error.

**USING**

The **USING** clause defines the discriminant columns in flexible domains. This clause is mandatory when associating columns with a flexible domain.

The columns in the **DOMAIN** and **USING** clauses must be different.

***datatype***

Specify the data type of a column.

In general, you must specify *datatype*. However, the following exceptions apply:

- You must omit *datatype* if you specify the **AS subquery** clause.
- You can also omit *datatype* if the statement designates the column as part of a foreign key in a referential integrity constraint. Oracle Database automatically assigns to the column the data type of the corresponding column of the referenced key of the referential integrity constraint.

**Restrictions on Table Column Data Types**

- Do not create a table with **LONG** columns. Use LOB columns (**CLOB**, **NCLOB**, **BLOB**) instead. **LONG** columns are supported only for backward compatibility.
- You can specify a column of type **ROWID**, but Oracle Database does not guarantee that the values in such columns are valid rowids.

 **See Also:**

["Data Types"](#) for information on **LONG** columns and on Oracle-supplied data types

You can specify a user-defined datatype as non-persistent when creating or altering the datatype. Instances of non-persistent types cannot persist on disk. See [CREATE TYPE](#) for more on user-defined datatypes declared as non-persistent types.

## RESERVABLE

Reservable columns provide for lock-free reservations. Lock-free reservations allow other concurrent transactions updating the reservable columns to proceed without being blocked. Lock-free reservations hold locks on hot data for short intervals of time and only when the value is modified during the commit of the transaction.

Specify `RESERVABLE` on a column to make it reservable on columns with numeric data type.

### Guidelines and Restrictions for Reservable Columns

- The schema definition of user tables declares the reservable columns with the `RESERVABLE` keyword.
- A reservable column can be specified only on columns of the following numeric data types: `NUMBER`, `INTEGER`, and `FLOAT`.
- A reservable column cannot be a Primary Key or an identity column (or virtual column) because the reservable column is an aggregate type.
- A user table can have at most ten reservable columns.
- User tables that have reservable columns must have a Primary Key.
- Indexes are not supported on reservable columns.
- Composite reservable columns are not allowed. Reservable columns can be included only in `CHECK` constraints expression.
- The `CHECK` constraint can be at the column-level or table-level. User-defined operational constraints are used for reservable columns to ensure application correctness.
- Partitioning cannot be made on reservable columns. Transactions with pending reservations must finalize before you can drop the reservable column or mark the column as `UNUSED`.

### See Also:

- *Using Lock-Free Reservation* of the *Database Development Guide*.
- Columns section in *Tables and Table Clusters* of *Database Concepts*.

## COLLATE

The `COLLATE` clause lets you specify a data-bound collation for the column.

For `column_collation_name`, specify a valid named collation or pseudo-collation. For columns of data type `CLOB` or `NCLOB`, the only allowed value for `column_collation_name` is the pseudo-collation `USING_NLS_COMP`.

If you omit this clause, then the column is assigned:

- the pseudo-collation `USING_NLS_COMP`, if the column has the data type `CLOB` or `NCLOB`, or
- the collation of the corresponding parent key column, if the column belongs to a foreign key, or
- the default collation for the table as it stands at the time the column is created.

Refer to the [DEFAULT COLLATION](#) clause for more information on the default collation for a table.

You can specify the `COLLATE` clause only if the `COMPATIBLE` initialization parameter is set to 12.2 or greater, and the `MAX_STRING_SIZE` initialization parameter is set to EXTENDED.

## SORT

The `SORT` keyword is valid only if you are creating this table as part of a hash cluster and only for columns that are also cluster columns.

Table rows are hashed into buckets on cluster key columns without `SORT`, and then sorted in each bucket on the columns with this clause. This may improve response time during subsequent operations on the clustered data.

### See Also:

- "[CLUSTER Clause](#)" for information on creating a cluster table
- [Managing Hash Clusters](#)

## VISIBLE | INVISIBLE

Use this clause to specify whether `column` is VISIBLE or INVISIBLE. The default is VISIBLE.

INVISIBLE columns are user-specified hidden columns. To display or assign a value to an INVISIBLE column, you must specify its name explicitly. For example:

- The `SELECT *` syntax will not display an INVISIBLE column. However, if you include an INVISIBLE column in the select list of a `SELECT` statement, then the column will be displayed.
- You cannot implicitly specify a value for an INVISIBLE column in the `VALUES` clause of an `INSERT` statement. You must specify the INVISIBLE column in the column list.
- You must explicitly specify an INVISIBLE column in Oracle Call Interface (OCI) describes.
- You can configure SQL\*Plus to allow INVISIBLE column information to be viewed with the `DESCRIBE` command. Refer to *SQL\*Plus User's Guide and Reference* for more information.

### Notes on VISIBLE and INVISIBLE Columns

The following notes apply to VISIBLE and INVISIBLE columns:

- An INVISIBLE column can be used as a partitioning key when specified as part of `CREATE TABLE`.
- You can specify INVISIBLE columns in a `column_expression`.
- A virtual column can be an INVISIBLE column.
- PL/SQL `%ROWTYPE` attributes do not show INVISIBLE columns.

- The COLUMN\_ID column of the ALL\_, DBA\_, and USER\_TAB\_COLUMNS data dictionary views determines the order in which a SELECT \* query returns columns for a table, view, or materialized view. The value of COLUMN\_ID is NULL for INVISIBLE columns. When you make an invisible column visible, it will be assigned the next highest available COLUMN\_ID value. When you make a visible column invisible, its COLUMN\_ID value is set to NULL and COLUMN\_ID is decremented by 1 for any columns with a higher COLUMN\_ID.

### Restrictions on VISIBLE and INVISIBLE Columns

The following restrictions apply to VISIBLE and INVISIBLE columns:

- INVISIBLE columns are not supported in external tables, cluster tables, or temporary tables.
- You cannot make a system-generated hidden column visible.

#### Note:

To determine whether a column is a system-generated hidden column, query the HIDDEN\_COLUMN and USER\_GENERATED columns of the ALL\_, DBA\_, and USER\_TAB\_COLS data dictionary views. Refer to *Oracle Database Reference* for more information.

### DEFAULT

The DEFAULT clause lets you specify a value to be assigned to the column if a subsequent INSERT statement omits a value for the column. The data type of the expression must match the data type specified for the column. The column must also be large enough to hold this expression.

The DEFAULT expression can include any SQL function as long as the function does not return a literal argument, a column reference, or a nested function invocation.

The DEFAULT expression can include the sequence pseudocolumns CURRVAL and NEXTVAL, as long as the sequence exists and you have the privileges necessary to access it. Users who perform subsequent inserts that use the DEFAULT expression must have the INSERT privilege on the table and the SELECT privilege on the sequence. If the sequence is later dropped, then subsequent INSERT statements where the DEFAULT expression is used will result in an error. If you do not fully qualify the sequence by specifying the sequence owner, for example, SCOTT.SEQ1, then Oracle Database will default the sequence owner to be the user who issues the CREATE TABLE statement. For example, if user MARY creates SCOTT.TABLE and refers to a sequence that is not fully qualified, such as SEQ2, then the column will use sequence MARY.SEQ2. Synonyms on sequences undergo a full name resolution and are stored as the fully qualified sequence in the data dictionary; this is true for public and private synonyms. For example, if user BETH adds a column referring to public or private synonym SYN1 and the synonym refers to PETER.SEQ7, then the column will store PETER.SEQ7 as the default.

### Restrictions on Default Column Values

Default column values are subject to the following restrictions:

- A DEFAULT expression cannot contain references to PL/SQL functions or to other columns, the pseudocolumns LEVEL, PRIOR, and ROWNUM, or date constants that are not fully specified.

- The expression can be of any form except a scalar subquery expression.

 **See Also:**

["About SQL Expressions"](#) for the syntax of `expr`

## ON NULL

If you specify the `ON NULL` clause, then Oracle Database assigns the `DEFAULT` column value when a subsequent `INSERT` statement attempts to assign a value that evaluates to `NULL`.

When you specify `ON NULL`, the `NOT NULL` constraint and `NOT DEFERRABLE` constraint state are implicitly specified. If you specify an inline constraint that conflicts with `NOT NULL` and `NOT DEFERRABLE`, then an error is raised.

If you specify `DEFAULT ON NULL FOR INSERT AND UPDATE`, the `DEFAULT ON NULL` semantics applies for `INSERT`, including the insert branch of merge and multi-table insert and `UPDATE`, including the update branch of merge.

If you specify `DEFAULT ON NULL FOR INSERT ONLY`, it is equivalent to `DEFAULT ON NULL`. It means that `DEFAULT ON NULL` semantics will apply for `INSERT` including the insert branch of merge and multi-table insert only.

In before-row DML triggers, `:new.column-name` shows the defaulted value, and you can override the default value in the trigger. If a column is defined as `DEFAULT ON NULL FOR INSERT AND UPDATE` and the trigger updates the value to `NULL`, then `DEFAULT ON NULL` semantics will not apply – i.e. `NULL` will not be converted to the column default value.

In the following trigger, column `c2` has `DEFAULT ON NULL` semantics. When the trigger is executed, an error is raised since it sets `c2` to `NULL`:

```
create or replace trigger t1_t
before insert or update on t1 for each row
begin
    :new.c2 := NULL;
end;
```

### Restriction on the ON NULL Clause

You cannot specify this clause for an object type column or a `REF` column.

 **See Also:**

["Creating a Table with a DEFAULT ON NULL Column Value: Example"](#)

### `annotations_clause`

The `annotation_name` is an identifier that can have up to 4000 characters. If the annotation name is a reserved word it must be provided in double quotes. When a

double quoted identifier is used, the identifier can also contain whitespace characters. However, identifiers that contain only whitespace characters are not accepted.

For examples see [Add Annotations at Table Creation: Example](#)

For the full semantics of the annotations clause see [annotations\\_clause](#).

### ***identity\_clause***

Use this clause to specify an identity column. The identity column will be assigned an increasing or decreasing integer value from a sequence generator for each subsequent `INSERT` statement. You can use the `identity_options` clause to configure the sequence generator.

#### **ALWAYS**

If you specify `ALWAYS`, then Oracle Database always uses the sequence generator to assign a value to the column. If you attempt to explicitly assign a value to the column using `INSERT` or `UPDATE`, then an error will be returned. This is the default.

#### **BY DEFAULT**

If you specify `BY DEFAULT`, then Oracle Database uses the sequence generator to assign a value to the column by default, but you can also explicitly assign a specified value to the column. If you specify `ON NULL`, then Oracle Database uses the sequence generator to assign a value to the column when a subsequent `INSERT` statement attempts to assign a value that evaluates to `NULL`. See [column\\_definition ON NULL](#) for full semantics.

### ***identity\_options***

Use the `identity_options` clause to configure the sequence generator. The `identity_options` clause has the same parameters as the `CREATE SEQUENCE` statement. Refer to [CREATE SEQUENCE](#) for a full description of these parameters and characteristics. The exception is `START WITH LIMIT VALUE`, which is specific to `identity_options` and can only be used with `ALTER TABLE MODIFY`. Refer to [identity\\_options](#) for more information.

#### **Note:**

When you create an identity column, Oracle recommends that you specify the `CACHE` clause with a value higher than the default of 20 to enhance performance.

## **Restrictions on Identity Columns**

Identity columns are subject to the following restrictions:

- You can specify only one identity column per table.
- If you specify `identity_clause`, then you must specify a numeric data type for `datatype` in the `column_definition` clause. You cannot specify a user-defined data type.
- If you specify `identity_clause`, then you cannot specify the `DEFAULT` clause in the `column_definition` clause.
- When you specify `identity_clause`, the `NOT NULL` constraint and `NOT DEFERRABLE` constraint state are implicitly specified. If you specify an inline constraint that conflicts with `NOT NULL` and `NOT DEFERRABLE`, then an error is raised.

- If an identity column is encrypted, then the encryption algorithm may be inferred. Oracle recommends that you use a strong encryption algorithm on identity columns.
- CREATE TABLE AS SELECT will not inherit the identity property on a column.

 **See Also:**

"[Creating a Table with an Identity Column: Examples](#)"

#### ***encryption\_spec***

Starting with Oracle Database 23c, the Transparent Data Encryption (TDE) decryption libraries for the GOST and SEED algorithms are deprecated.

GOST 28147-89 has been deprecated by the Russian government, and SEED has been deprecated by the South Korean government. If you need South Korean government-approved TDE cryptography, then use ARIA instead. If you are using GOST 28147-89, then you must decrypt and encrypt with another supported TDE algorithm. The decryption algorithms for GOST 28147-89 and SEED are included in Oracle Database 23c, but are deprecated, and the GOST encryption algorithm is unsupported with Oracle Database 23c. If you are using GOST or SEED for TDE encryption, then Oracle recommends that you decrypt and encrypt with another algorithm before upgrading to Oracle Database 23c. However, with the exception of the HP Itanium platform, the GOST and SEED decryption libraries are available with Oracle Database 23c, so you can also decrypt after upgrading.

The ENCRYPT clause lets you use the Transparent Data Encryption (TDE) feature to encrypt the column you are defining. You can encrypt columns of type CHAR, NCHAR, VARCHAR2, NVARCHAR2, NUMBER, DATE, LOB, and RAW. The data does not appear in its encrypted form to authorized users, such as the user who encrypts the column.

 **Note:**

- Column encryption requires that a system administrator with appropriate privileges has initialized the security module, opened a keystore, and set an encryption key. Refer to *Oracle Database Advanced Security Guide* for general information about column encryption and to [\*security\\_clauses\*](#) for related ALTER SYSTEM statements.

#### **USING '*encrypt\_algorithm*'**

Use this clause to specify the name of the algorithm to be used. Valid algorithms are AES256, AES192, AES128 and 3DES168. If the COMPATIBLE initialization parameter is set to 12.2 or higher, then the following algorithms are also valid: ARIA128, ARIA192, ARIA256, GOST256, and SEED128. If you omit this clause, then the database uses AES192. If you encrypt more than one column in the same table, and if you specify the USING clause for one of the columns, then you must specify the same encryption algorithm for all the encrypted columns.

#### **IDENTIFIED BY *password***

If you specify this clause, then the database derives the column key from the specified password.

#### 'integrity\_algorithm'

Use this clause to specify the integrity algorithm to be used. Valid integrity algorithms are `SHA-1` and `NOMAC`.

- If you specify `SHA-1`, then TDE uses the Secure Hash Algorithm (SHA-1) and adds a 20-byte Message Authentication Code (MAC) to each encrypted value for integrity checking. This is the default.
- If you specify `NOMAC`, then TDE does not add a MAC and does not perform the integrity check. This saves 20 bytes of disk space per encrypted value. Refer to *Oracle Database Advanced Security Guide* for more information on using `NOMAC` to save disk space and improve performance.

All encrypted columns in a table must use the same integrity algorithm. If you already have a table column using the `SHA-1` algorithm, then you cannot use the `NOMAC` parameter to encrypt another column in the same table. Refer to the `REKEY encryption_spec` clause of `ALTER TABLE` to learn how to change the integrity algorithm used by all encrypted columns in a table.

#### SALT | NO SALT

Specify `SALT` to instruct the database to append a random string, called "salt," to the clear text of the column before encrypting it. This is the default.

Specify `NO SALT` to prevent the database from appending salt to the clear text of the column before encrypting it.

The following considerations apply when specifying `SALT` or `NO SALT` for encrypted columns:

- If you want to use the column as an index key, then you must specify `NO SALT`. Refer to *Oracle Database Advanced Security Guide* for a description of "salt" in this context.
- If you specify table compression for the table, then the database does not compress the data in encrypted columns with `SALT`.

You cannot specify `SALT` or `NO SALT` for LOB encryption.

#### Restrictions on `encryption_spec`

The following restrictions apply to column encryption:

- Transparent Data Encryption is not supported by the traditional import and export utilities or by transportable-tablespace-based export. Use the Data Pump import and export utilities with encrypted columns instead.
- To encrypt a column in an external table, the table must use `ORACLE_DATAPUMP` as its access type.
- You cannot encrypt a column in tables owned by `SYS`.
- You cannot encrypt a foreign key column.

#### See Also:

*Oracle Database Advanced Security Guide* for more information about Transparent Data Encryption

***virtual\_column\_definition***

The *virtual\_column\_definition* clause lets you create a virtual column. A virtual column is not stored on disk. Rather, the database derives the values in a virtual column on demand by computing a set of expressions or functions. Virtual columns can be used in queries, DML, and DDL statements. They can be indexed, and you can collect statistics on them. Thus, they can be treated much as other columns.

Exceptions and restrictions are listed below in "[Notes on Virtual Columns](#)" and "[Restrictions on Virtual Columns](#)".

***column***

For *column*, specify the name of the virtual column.

***datatype***

You can optionally specify the data type of the virtual column. If you omit *datatype*, then the database determines the data type of the column based on the data type of the underlying expressions. All Oracle scalar data types and `XMLType` are supported.

**COLLATE**

The `COLLATE` clause lets you specify a data-bound collation for the virtual column. For *column\_collation\_name*, specify a valid named collation or pseudo-collation. If you omit this clause, then the column is assigned the default collation for the table as it stands at the time the column is created, unless the column belongs to a foreign key, in which case it inherits the collation from the corresponding column of the parent key. Refer to the `DEFAULT COLLATION` clause for more information on the default collation for a table.

You can specify the `COLLATE` clause only if the `COMPATIBLE` initialization parameter is set to 12.2 or greater, and the `MAX_STRING_SIZE` initialization parameter is set to EXTENDED.

**VISIBLE | INVISIBLE**

Use this clause to specify whether virtual column is `VISIBLE` or `INVISIBLE`. The default is `VISIBLE`. For complete information, refer to "[VISIBLE | INVISIBLE](#)".

**GENERATED ALWAYS**

The optional keywords `GENERATED ALWAYS` are provided for semantic clarity. They indicate that the column is not stored on disk, but is evaluated on demand.

***column\_expression***

The `AS column_expression` clause determines the content of the column. Refer to "[Column Expressions](#)" for more information on *column\_expression*.

**VIRTUAL**

The optional keyword `VIRTUAL` is provided for semantic clarity.

***evaluation\_edition\_clause***

You must specify this clause if *column\_expression* refers to an editioned PL/SQL function. Use this clause to specify the edition that is searched during name resolution of the editioned PL/SQL function—the evaluation edition.

- Specify CURRENT EDITION to search the edition in which this DDL statement is executed.
- Specify EDITION *edition* to search *edition*.
- Specifying NULL EDITION is equivalent to omitting the *evaluation\_edition\_clause*.

If you omit the *evaluation\_edition\_clause*, then editioned objects are invisible during name resolution and an error will result. If the evaluation edition is dropped, then a subsequent query on the virtual column will result in an error.

The database does not maintain dependencies on the functions referenced by a virtual column. Therefore, if a virtual column refers to a noneditioned function, and the function becomes editioned, then the following operations may raise an error:

- Querying the virtual column
- Updating a row that includes the virtual column
- Firing a trigger that accesses the virtual column

#### See Also:

*Oracle Database Development Guide* for more information on specifying the evaluation edition for a virtual column

#### unusable\_editions\_clause

This clause lets you specify that the virtual column expression is unusable for evaluating queries in one or more editions. The remaining editions form a range of editions in which it is safe for the optimizer to use the virtual column expression to evaluate queries.

For example, suppose you define a function-based index on the virtual column. The optimizer can use the function-based index to evaluate queries that contain the virtual column expression in their WHERE clause. If a query is compiled in an edition that is in the usable range of editions for the virtual column, then the optimizer will consider using the index to evaluate the query. If a query is compiled in an edition outside the usable range of editions for the virtual column, then the optimizer will not consider using the index.

#### See Also:

*Oracle Database Concepts* for more information on optimization with function-based indexes

#### **UNUSABLE BEFORE Clause**

This clause lets you specify that the virtual column expression is unusable for evaluating queries in the ancestors of an edition.

- If you specify CURRENT EDITION, then the virtual column expression is unusable in the ancestors of the edition in which this DDL statement is executed.
- If you specify EDITION *edition*, then the virtual column expression is unusable in the ancestors of the specified *edition*.

#### **UNUSABLE BEGINNING WITH Clause**

This clause lets you specify that the virtual column expression is unusable for evaluating queries in an edition and its descendants.

- If you specify CURRENT EDITION, then the virtual column expression is unusable in the edition in which this DDL statement is executed and its descendants.
- If you specify EDITION *edition*, then the virtual column expression is unusable in the specified *edition* and its descendants.
- Specifying NULL EDITION is equivalent to omitting the UNUSABLE BEGINNING WITH clause.

If an edition specified in this clause is subsequently dropped, there is no effect on the virtual column.

### Notes on Virtual Columns

- If *column\_expression* refers to a column on which column-level security is implemented, then the virtual column does not inherit the security rules of the base column. In such a case, you must ensure that data in the virtual column is protected, either by duplicating a column-level security policy on the virtual column or by applying a function that implicitly masks the data. For example, it is common for credit card numbers to be protected by a column-level security policy, while still allowing call center employees to view the last four digits of the credit card number for validation purposes. In such a case, you could define the virtual column to take a substring of the last four digits of the credit card number.
- A table index defined on a virtual column is equivalent to a function-based index on the table.
- You cannot directly update a virtual column. Thus, you cannot specify a virtual column in the SET clause of an UPDATE statement. However, you can specify a virtual column in the WHERE clause of an UPDATE statement. Likewise, you can specify a virtual column in the WHERE clause of a DELETE statement to delete rows from a table based on the derived value of the virtual column.
- A query that specifies in its FROM clause a table containing a virtual column is eligible for result caching. Refer to "RESULT\_CACHE Hint" for more information on result caching.
- The *column\_expression* can refer to a PL/SQL function if the function is explicitly designated DETERMINISTIC during its creation. However, if the function is subsequently replaced, definitions dependent on the virtual column are not invalidated. In such a case, if the table contains data, queries that reference the virtual column may return incorrect results if the virtual column is used in the definition of constraints, indexes, or materialized views or for result caching. Therefore, in order to replace the deterministic PL/SQL function for a virtual column.
  - Disable and re-enable any constraints on the virtual column.
  - Rebuild any indexes on the virtual column.
  - Fully refresh materialized views accessing the virtual column.
  - Flush the result cache if cached queries have accessed the virtual column.
  - Regather statistics on the table.
- A virtual column can be an INVISIBLE column. The *column\_expression* can contain INVISIBLE columns.

## Restrictions on Virtual Columns

- You can create virtual columns only in relational heap tables. Virtual columns are not supported for index-organized, external, object, cluster, or temporary tables.
- The *column\_expression* in the AS clause has the following restrictions:
  - It cannot refer to another virtual column by name.
  - Any columns referenced in *column\_expression* must be defined on the same table.
  - It can refer to a deterministic user-defined function, but if it does, then you cannot use the virtual column as a partitioning key column.
  - The output of *column\_expression* must be a scalar value.

 **See Also:**

"[Column Expressions](#)" for additional information and restrictions on *column\_expression*

- The virtual column cannot be an Oracle supplied data type, a user-defined type, or LOB or LONG RAW.
- You cannot specify a call to a PL/SQL function in the defining expression for a virtual column that you want to use as a partitioning column.

 **See Also:**

"[Adding a Virtual Table Column: Example](#)" and *Oracle Database Administrator's Guide* for examples of creating tables with virtual columns

### ***period\_definition***

Use the *period\_definition* clause to create a valid time dimension for *table*.

This clause implements Temporal Validity support for *table*. If you specify this clause, then one column in *table*, the start time column, contains a start date or timestamp, and another column in *table*, the end time column, contains an end date or timestamp. These two columns define a valid time dimension for *table*—that is, a period of time for which each row is considered valid. You can use Oracle Flashback Query to retrieve rows from *table* based on whether they are considered valid as of a specified time, before a specified time, or during a specified time period.

You can specify at most one valid time dimension when you create a table. You can subsequently add additional valid time dimensions to a table with the [add\\_period\\_clause](#) of ALTER TABLE.

### ***valid\_time\_column***

Specify the name of the valid time dimension. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)". Oracle Database creates an INVISIBLE virtual column with this name of data type NUMBER in *table*.

### ***start\_time\_column* and *end\_time\_column***

You can optionally specify these clauses as follows:

- Use *start\_time\_column* to specify the name of the start time column, which contains the start date or timestamp.
- Use *end\_time\_column* to specify the name of the end time column, which contains the end date or timestamp.

The names you specify for *start\_time\_column* and *end\_time\_column* must satisfy the requirements listed in "[Database Object Naming Rules](#)".

If you specify these clauses, then you must define *start\_time\_column* and *end\_time\_column* in the *column\_definition* clause of CREATE TABLE. Each column must be of a datetime data type (DATE, TIMESTAMP, TIMESTAMP WITH TIME ZONE, or TIMESTAMP WITH LOCAL TIME ZONE) and can be VISIBLE or INVISIBLE.

If you do not specify these clauses, then Oracle Database creates a start time column named *valid\_time\_column\_START*, and an end time column named *valid\_time\_column\_END*. These columns are of data type TIMESTAMP WITH TIME ZONE and are INVISIBLE.

You can insert and update values in the start time column and end time column as you would any column, with the following considerations:

- If the value of the start time column is NULL, then the row is considered valid for all time values that occur before, but not including, the value of the end time column.
- If the value of the end time column is NULL, then the row is considered valid for all time values that occur on or after the value of the start time column.
- If the value of neither column is NULL, then the value of the start time column must be earlier than the value of the end time column. The row is considered valid for all time values that occur on or after the value of the start time column, and up to, but not including, the value of the end time column.
- If the value of both columns is NULL, then the row is considered valid for all time values.

### Restrictions on Valid Time Dimension Columns

The following restrictions apply to valid time dimension columns:

- The *valid\_time\_column* is for internal use only. You cannot perform DDL or DML operations on it with one exception: You can drop the column by using the *drop\_period\_clause* of ALTER TABLE.
- You can drop the start time column and end time column only by using the *drop\_period\_clause* of ALTER TABLE.
- If the start time column and end time column are automatically created by Oracle Database, then they are INVISIBLE and you cannot subsequently make them VISIBLE.

 **See Also:**

- *Oracle Database Development Guide* for more information on Temporal Validity
- SELECT [flashback\\_query\\_clause](#) for more information on Oracle Flashback Query
- ALTER TABLE [add\\_period\\_clause](#) and [drop\\_period\\_clause](#) for information how to add and drop a valid time dimension

**Constraint Clauses**

Use these clauses to create constraints on the table columns. You must specify a PRIMARY KEY constraint for an index-organized table, and it cannot be DEFERRABLE. Refer to [constraint](#) for syntax and description of these constraints as well as examples.

***inline\_ref\_constraint* and *out\_of\_line\_ref\_constraint***

These clauses let you describe a column of type REF. The only difference between these clauses is that you specify *out\_of\_line\_ref\_constraint* from the table level, so you must identify the REF column or attribute you are defining. Specify *inline\_ref\_constraint* as part of the definition of the REF column or attribute.

 **See Also:**

["REF Constraint Examples"](#)

***inline\_constraint***

Use the *inline\_constraint* to define an integrity constraint as part of the column definition.

You can create UNIQUE, PRIMARY KEY, and REFERENCES constraints on scalar attributes of object type columns. You can also create NOT NULL constraints on object type columns and CHECK constraints that reference object type columns or any attribute of an object type column.

***out\_of\_line\_constraint***

Use the *out\_of\_line\_constraint* syntax to define an integrity constraint as part of the table definition.

***supplemental\_logging\_props***

The *supplemental\_logging\_props* clause lets you instruct the database to put additional data into the log stream to support log-based tools.

***supplemental\_log\_grp\_clause***

Use this clause to create a named log group.

- The NO LOG clause lets you omit from the redo log one or more columns that would otherwise be included in the redo for the named log group. You must specify at least one fixed-length column without NO LOG in the named log group.

- If you specify `ALWAYS`, then during an update, the database includes in the redo all columns in the log group. This is called an **unconditional log group** (sometimes called an "always log group"), because Oracle Database supplementally logs all the columns in the log group when the associated row is modified. If you omit `ALWAYS`, then the database supplementally logs all the columns in the log group only if any column in the log group is modified. This is called a **conditional log group**.

You can query the appropriate `USER_`, `ALL_`, or `DBA_LOG_GROUP_COLUMNS` data dictionary view to determine whether any supplemental logging has already been specified.

#### ***supplemental\_id\_key\_clause***

Use this clause to specify that all or a combination of the primary key, unique key, and foreign key columns should be supplementally logged. Oracle Database will generate either an **unconditional log group** or a **conditional log group**. With an unconditional log group, the database supplementally logs all the columns in the log group when the associated row is modified. With a conditional log group, the database supplementally logs all the columns in the log group only if any column in the log group is modified.

- If you specify `ALL COLUMNS`, then the database includes in the redo log all the fixed-length maximum size columns of that row. Such a redo log is a system-generated unconditional log group.
- If you specify `PRIMARY KEY COLUMNS`, then for all tables with a primary key, the database places into the redo log all columns of the primary key whenever an update is performed. Oracle Database evaluates which columns to supplementally log as follows:
  - First the database chooses columns of the primary key constraint, if the constraint is validated or marked `RELY` and is not marked as `DISABLED` or `INITIALLY DEFERRED`.
  - If no primary key columns exist, then the database looks for the smallest `UNIQUE` index with at least one `NOT NULL` column and uses the columns in that index.
  - If no such index exists, then the database supplementally logs all scalar columns of the table.
- If you specify `UNIQUE COLUMNS`, then for all tables with a unique key or a bitmap index, if any of the unique key or bitmap index columns are modified, the database places into the redo log all other columns belonging to the unique key or bitmap index. Such a log group is a system-generated conditional log group.
- If you specify `FOREIGN KEY COLUMNS`, then for all tables with a foreign key, if any foreign key columns are modified, the database places into the redo log all other columns belonging to the foreign key. Such a redo log is a system-generated conditional log group.

If you specify this clause multiple times, then the database creates a separate log group for each specification. You can query the appropriate `USER_`, `ALL_`, or `DBA_LOG_GROUPS` data dictionary view to determine whether any supplemental logging data has already been specified.

#### ***immutable\_table\_clauses***

You must specify this clause when you create an immutable table.

#### **Example: Create an Immutable Table**

The following example creates an immutable table named `trade_ledger` in your user schema. The immutable table can be dropped only after 40 days of inactivity. Rows cannot be deleted until 100 days after they have been inserted.

```
CREATE IMMUTABLE TABLE trade_ledger (tr_id NUMBER, user_name VARCHAR2(40),
tr_value NUMBER)

    NO DROP UNTIL 40 DAYS IDLE

    NO DELETE UNTIL 100 DAYS AFTER INSERT;
```

### ***blockchain\_table\_clauses***

When you create a blockchain table, you must specify the `blockchain_table_clauses`:

- `blockchain_drop_table_clause`
- `blockchain_row_retention_clause`
- `blockchain_hash_clause`
- `blockchain_data_format_clause`

### ***blockchain\_drop\_table\_clause***

```
NO DROP [ UNTIL integer DAYS IDLE ]
```

Use `integer` to specify the number of days that the blockchain table must be idle (i.e. have no rows inserted). The minimum idle retention period is 0 days, but the recommended idle retention period is 16 days.

You can specify this clause in two ways:

- `NO DROP` means that the blockchain table cannot be dropped.
- `NO DROP UNTIL integer DAYS IDLE` means that the blockchain table cannot be dropped, if the newest row is less than `integer` of days old.

### ***blockchain\_row\_retention\_clause***

```
NO DELETE [ LOCKED ]
| NO DELETE UNTIL integer DAYS AFTER INSERT [LOCKED]
```

- `integer` specifies the idle retention period for inserted rows before they can be deleted. The minimum idle retention period for inserted rows is 16 days.
- If you specify `LOCKED`, then you cannot change the retention period using `ALTER TABLE`.
- If you do not specify `LOCKED` in the clause `UNTIL number DAYS AFTER INSERT`, then you can change the retention period using `ALTER TABLE`, but only to a value higher than the previous retention period.
- If you specify `NO DELETE LOCKED`, then you cannot delete any rows from this table. But you can drop the entire table if the table is inactive for more than the number of days specified in the `blockchain_drop_table_clause`.

### ***blockchain\_hash\_clause***

```
HASHING USING sha2_512
```

You must specify this clause last after `blockchain_drop_table_clause` and `blockchain_row_retention_clause` when you create a blockchain table.

You cannot specify this clause to modify a blockchain table using the `ALTER TABLE` statement.

#### ***blockchain\_row\_version\_user\_chain\_clause***

##### **WITH ROW VERSION**

This clause is optional and can only be specified on VERSION V2 blockchain tables. You can specify at most three user-defined columns with the clause. The name of the row version sequence identified by `row_version_name` is used to verify the user chain. The types of the columns are restricted to NUMBER, CHAR, VARCHAR2, and RAW. When the clause is specified, rows with identical values in the specified user-defined columns are sequenced using the Oracle managed hidden column `ORABCTAB_ROW_VERSION$`.

##### **Example: Row Versions**

```
CREATE BLOCKCHAIN TABLE bank_ledger (bank VARCHAR2(128), account_no NUMBER,  
deposit_date DATE, deposit_amount NUMBER)  
    NO DROP UNTIL 31 DAYS IDLE  
    NO DELETE LOCKED  
    HASHING USING SHA2_512 WITH ROW VERSION ACCOUNT_NO (bank, account_no)  
VERSION V2;
```

##### **AND USER CHAIN**

The optional `AND USER CHAIN` clause can only be specified on VERSION V2 blockchain tables as part of the `WITH ROW VERSION` clause. It extends the functionality offered by the row versions and links these rows in a separate (user) blockchain. At most three user-defined columns can be specified to define a user chain. The name of the user chain is that specified in the `WITH ROW VERSION` clause. The sequencing of the rows in the user chain is accomplished using column `ORABCTAB_ROW_VERSION$`. The crypto hash is maintained in column `ORABCTAB_USER_CHAIN_HASH$`. Note, that `ORABCTAB_USER_CHAIN_HASH$` is not signed in V2 blockchain tables. Only the system crypto hash can be signed (with signature stored in `ORABCTAB_SIGNATURE$` or `ORABCTAB_DELEGATE_SIGNATURE$` column).

##### **Example: AND USER CHAIN**

```
CREATE BLOCKCHAIN TABLE bank_ledger (bank VARCHAR2(128), account_no NUMBER,  
deposit_date DATE, deposit_amount NUMBER)  
    NO DROP UNTIL 31 DAYS IDLE  
    NO DELETE LOCKED  
    HASHING USING SHA2_512 WITH ROW VERSION AND USER CHAIN bank_accounts  
(bank, account_no) VERSION V2;
```

#### ***blockchain\_system\_chains\_clause***

Specify this clause to override the default of 32 system chains per instance. The number of system chains configured by this clause must be between 1 and 1024.

#### ***blockchain\_data\_format\_clause***

You must specify the version when you create a blockchain table, either `v1` or `v2`. Version `V2` creates additional Oracle managed hidden columns than `V1`.

You cannot use `ALTER TABLE` to convert version from `V1` to `V2` and vice versa.

### Example: HASHING and VERSION

```
CREATE BLOCKCHAIN TABLE bank_ledger (bank VARCHAR2(128), deposit_date DATE,  
deposit_amount NUMBER)  
    NO DROP UNTIL 31 DAYS IDLE  
    NO DELETE LOCKED  
    HASHING USING SHA2_512 VERSION V2;
```

### DEFAULT COLLATION

This clause lets you specify the default collation for the table. The default collation is assigned to columns of the table that are of a character data type and are created with this statement or subsequently added to the table with an `ALTER TABLE` statement. For `collation_name`, specify a valid named collation or pseudo-collation.

If you omit this clause, then the default collation for the table is set to the effective schema default collation of the schema containing the table. Refer to the `DEFAULT_COLLATION` clause of `ALTER SESSION` for more information on the effective schema default collation.

You can override the table's default collation and assign a data-bound collation to a particular column by specifying the `COLLATE` clause in the `column_definition` or `virtual_column_definition` clause of `CREATE TABLE` or `ALTER TABLE`, or the `modify_col_properties` or `modify_virtcol_properties` clause of `ALTER TABLE`.

You can specify the `DEFAULT COLLATION` clause only if the `COMPATIBLE` initialization parameter is set to 12.2 or greater, and the `MAX_STRING_SIZE` initialization parameter is set to `EXTENDED`.

### Restriction on Collation for CLOB and NCLOB Columns

If a column has the data type of `CLOB` or `NCLOB`, then its specified collation must be `USING_NLS_COMP`. The collation of `CLOB` and `NCLOB` columns is always `USING_NLS_COMP` and is not affected by the default collation for the table.

#### See Also:

*Oracle Database Globalization Support Guide* for full information on default collations and data-bound collations

### ON COMMIT

The `ON COMMIT` clause is relevant only if you are creating a global temporary table. This clause specifies whether the data in the temporary table persists for the duration of a transaction or a session.

### DELETE ROWS

Specify `DELETE ROWS` for a transaction-specific temporary table. This is the default. Oracle Database will truncate the table (delete all its rows) after each commit.

### PRESERVE ROWS

Specify `PRESERVE ROWS` for a session-specific temporary table. Oracle Database will truncate the table (delete all its rows) when you terminate the session.

You can define the scope of a private temporary table using `ON COMMIT`. Use `DROP DEFINITION` to define a transaction-specific table and `PRESERVE DEFINITION` to define a session-specific table .

### **DROP DEFINITION**

Specify `DROP DEFINITION` to create a private temporary table whose content and definition are dropped when the transaction commits. The scope of this private temporary table is limited to the transaction. This is the default.

### **PRESERVE DEFINITION**

Specify `PRESERVE DEFINITION` to create a private temporary table whose definition is preserved when the transaction commits. The scope of this private temporary table is extended to the session.

#### ***physical\_properties***

The physical properties relate to the treatment of extents and segments and to the storage characteristics of the table.

#### **INTERNAL | EXTERNAL**

Use the keyword `INTERNAL` to indicate an internal partition. This is the default. Use the keyword `EXTERNAL` to indicate an external partition.

#### ***deferred\_segment\_creation***

Use this clause to determine when the database should create the segment(s) for this table:

- `SEGMENT CREATION DEFERRED`: This clause defers creation of the table segment — as well as segments for any LOB columns of the table, any indexes created implicitly as part of table creation, and any indexes subsequently explicitly created on the table — until the first row of data is inserted into the table. At that time, the segments for the table, LOB columns and indexes, and explicitly created indexes are all materialized and inherit any storage properties specified in this `CREATE TABLE` statement or, in the case of explicitly created indexes, the `CREATE INDEX` statement. These segments are created regardless whether the initial insert operation is uncommitted or rolled back. This is the default value.

#### **Caution:**

When creating many tables with deferred segment creation, ensure that you allocate enough space for your database so that when the first rows are inserted, there is enough space for all the new segments.

- `SEGMENT CREATION IMMEDIATE`: The table segment is created as part of this `CREATE TABLE` statement.

Immediate segment creation is useful, for example, if your application depends upon the object appearing in the `DBA_`, `USER_`, and `ALL_SEGMENTS` data dictionary views, because the object will not appear in those views until the segment is created. This clause overrides the setting of the `DEFERRED_SEGMENT_CREATION` initialization parameter.

To determine whether a segment has been created for an existing table or its LOB columns or indexes, query the `SEGMENT_CREATED` column of `USER_TABLES`, `USER_INDEXES`, or `USER_LOBS`.

### Notes on Tables Without Segments

The following rules apply to a table whose segment has not yet been materialized:

- If you create this table with `CREATE TABLE ... AS subquery`, then if the source table has no rows, segment creation of the new table is deferred. If the source table has rows, then segment creation of the new table is not deferred.
- If you specify `ALTER TABLE ... ALLOCATE EXTENT` before the segment is materialized, then the segment is materialized and then an extent is allocated. However the `ALLOCATE EXTENT` clause in a DDL statement on any indexes of the table will return an error.
- In a DDL statement on the table or its LOB columns or indexes, any specification of `DEALLOCATE UNUSED` is silently ignored.
- `ONLINE` operations on indexes of a table or table partition without a segment will silently be disabled; that is, they will proceed `OFFLINE`.
- If any of the following DDL statements are executed on a table with one or more LOB columns, then the resulting partition(s) or subpartition(s) will be materialized:
  - `ALTER TABLE SPLIT [SUB]PARTITION`
  - `ALTER TABLE MERGE [SUB]PARTITIONS`
  - `ALTER TABLE ADD [SUB]PARTITION` (hash partitions only)
  - `ALTER TABLE COALESCE [SUB]PARTITION` (hash partitions only)

### Restrictions on Deferred Segment Creation

This clause is subject to the following restrictions:

- You cannot defer segment creation for the following types of tables: clustered tables, global temporary tables, session-specific temporary tables, internal tables, external tables, and tables owned by `SYS`, `SYSTEM`, `PUBLIC`, `OUTLN`, or `XDB`.
- Deferred segment creation is not supported in dictionary-managed tablespaces.
- Deferred segment creation is not supported in the `SYSTEM` tablespace.
- Serializable transactions do not work with deferred segment creation. Trying to insert data into an empty table with no segment created causes an error.

#### See Also:

*Oracle Database Concepts* for general information on segment allocation and  
*Oracle Database Reference* for more information about the  
`DEFERRED_SEGMENT_CREATION` initialization parameter

#### segment\_attributes\_clause

The `segment_attributes_clause` lets you specify physical attributes and tablespace storage for the table.

#### physical\_attributes\_clause

The *physical\_attributes\_clause* lets you specify the value of the PCTFREE, PCTUSED, and INITTRANS parameters and the storage characteristics of the table.

- For a nonpartitioned table, each parameter and storage characteristic you specify determines the actual physical attribute of the segment associated with the table.
- For partitioned tables, the value you specify for the parameter or storage characteristic is the default physical attribute of the segments associated with all partitions specified in this CREATE statement (and in subsequent ALTER TABLE ... ADD PARTITION statements), unless you explicitly override that value in the PARTITION clause of the statement that creates the partition.

If you omit this clause, then Oracle Database sets PCTFREE to 10, PCTUSED to 40, and INITTRANS to 1.

#### See Also:

- [physical\\_attributes\\_clause](#) and [storage\\_clause](#) for a description of these clauses
- ["Creating a Table: Storage Example"](#)

### TABLESPACE

Specify the tablespace in which Oracle Database creates the table, object table OIDINDEX, partition, LOB data segment, LOB index segment, or index-organized table overflow data segment. If you omit TABLESPACE, then the database creates that item in the default tablespace of the owner of the schema containing the table.

For a heap-organized table with one or more LOB columns, if you omit the TABLESPACE clause for LOB storage, then the database creates the LOB data and index segments in the tablespace where the table is created.

For an index-organized table with one or more LOB columns, if you omit TABLESPACE, then the LOB data and index segments are created in the tablespace in which the primary key index segment of the index-organized table is created.

For nonpartitioned tables, the value specified for TABLESPACE is the actual physical attribute of the segment associated with the table. For partitioned tables, the value specified for TABLESPACE is the default physical attribute of the segments associated with all partitions specified in the CREATE statement and on subsequent ALTER TABLE ... ADD PARTITION statements, unless you specify TABLESPACE in the PARTITION description.

#### See Also:

[CREATE TABLESPACE](#) for more information on tablespaces

### TABLESPACE SET

This clause is valid only when creating a sharded table by specifying the SHARDED keyword of CREATE TABLE. Use this clause to specify the tablespace set in which Oracle Database creates the table.

You can only associate a tablespace set with one table family when you use the CREATE SHARDED TABLE statement. If you try to use a tablespace set with more than one table family, an error will be thrown .

#### ***logging\_clause***

Specify whether the creation of the table and of any indexes required because of constraints, partition, or LOB storage characteristics will be logged in the redo log file (LOGGING) or not (NOLOGGING).The logging attribute of the table is independent of that of its indexes.

This attribute also specifies whether subsequent direct loader (SQL\*Loader) and direct-path INSERT operations against the table, partition, or LOB storage are logged (LOGGING) or not logged (NOLOGGING).

Refer to [logging\\_clause](#) for a full description of this clause.

#### ***table\_compression***

The *table\_compression* clause is valid only for heap-organized tables. Use this clause to instruct the database whether to compress data segments to reduce disk use. The COMPRESS clauses enable table compression. The NOCOMPRESS clause disables table compression. The default is NOCOMPRESS.

#### **COMPRESS**

Specifying only the keyword COMPRESS is equivalent to specifying ROW STORE COMPRESS BASIC and enables basic table compression.

#### **ROW STORE COMPRESS BASIC**

When you enable table compression by specifying either ROW STORE COMPRESS or ROW STORE COMPRESS BASIC, you enable **basic table compression**. Oracle Database attempts to compress data during direct-path INSERT operations when it is productive to do so. The original import utility (imp) does not support direct-path INSERT, and therefore cannot import data in a compressed format.

Tables with basic table compression use a PCTFREE value of 0 to maximize compression, unless you explicitly set a value for PCTFREE in the *physical\_attributes\_clause*.

In earlier releases, basic table compression was enabled using COMPRESS BASIC. This syntax is still supported for backward compatibility.

#### **See Also:**

"Conventional and Direct-Path INSERT" for information on direct-path INSERT operations, including restrictions

#### **ROW STORE COMPRESS ADVANCED**

When you enable table compression by specifying `ROW STORE COMPRESS ADVANCED`, you enable **Advanced Row Compression**. Oracle Database compresses data during all DML operations on the table. This form of compression is recommended for OLTP environments.

Tables with `ROW STORE COMPRESS ADVANCED` or `NOCOMPRESS` use the `PCTFREE` default value of 10, to maximize compress while still allowing for some future DML changes to the data, unless you override this default explicitly.

In earlier releases, Advanced Row Compression was called OLTP table compression and was enabled using `COMPRESS FOR OLTP`. This syntax is still supported for backward compatibility.

### COLUMN STORE COMPRESS FOR { QUERY | ARCHIVE }

When you specify `COLUMN STORE COMPRESS FOR QUERY` or `COLUMN STORE COMPRESS FOR ARCHIVE`, you enable **Hybrid Columnar Compression**. With Hybrid Columnar Compression, data can be compressed during direct-path inserts, conventional inserts, and array inserts. During the load process, data is transformed into a column-oriented format and then compressed. Oracle Database uses a compression algorithm appropriate for the level you specify. In general, the higher the level, the greater the compression ratio. Hybrid Columnar Compression can result in higher compression ratios, at a greater CPU cost. Therefore, this form of compression is recommended for data that is not frequently updated.

`COLUMN STORE COMPRESS FOR QUERY` is useful in data warehousing environments. Valid values are `LOW` and `HIGH`, with `HIGH` providing a higher compression ratio. The default is `HIGH`.

`COLUMN STORE COMPRESS FOR ARCHIVE` uses higher compression ratios than `COLUMN STORE COMPRESS FOR QUERY`, and is useful for compressing data that will be stored for long periods of time. Valid values are `LOW` and `HIGH`, with `HIGH` providing the highest possible compression ratio. The default is `LOW`.

Specifying `COLUMN STORE COMPRESS` is equivalent to specifying `COLUMN STORE COMPRESS FOR QUERY HIGH`.

Tables with `COLUMN STORE COMPRESS FOR QUERY` or `COLUMN STORE COMPRESS FOR ARCHIVE` use a `PCTFREE` value of 0 to maximize compression, unless you explicitly set a value for `PCTFREE` in the `physical_attributes_clause`. For these tables, `PCTFREE` has no effect for blocks loaded using direct-path `INSERT`. `PCTFREE` is honored for blocks loaded using conventional `INSERT`, and for blocks created as a result of DML operations on blocks originally loaded using direct-path `INSERT`.

### [NO] ROW LEVEL LOCKING

If you specify `ROW LEVEL LOCKING`, then Oracle Database uses row-level locking during DML operations. This improves the performance of these operations when accessing Hybrid Columnar Compressed data. If you specify `NO ROW LEVEL LOCKING`, then row-level locking is not used. The default is `NO ROW LEVEL LOCKING`.

In earlier releases, Hybrid Columnar Compression was enabled using `COMPRESS FOR QUERY` and `COMPRESS FOR ARCHIVE`. This syntax is still supported for backward compatibility.

 **See Also:**

*Oracle Database Concepts* for more information on Hybrid Columnar Compression, which is a feature of certain Oracle storage systems

### Notes on Table Compression

You can specify table compression for the following portions of a heap-organized table:

- For an entire table, in the `physical_properties` clause of `relational_table` or `object_table`
- For a range partition, in the `table_partition_description` of the `range_partitions` clause
- For a composite range partition, in the `table_partition_description` of the `range_partition_desc` clause
- For a composite list partition, in the `table_partition_description` of the `list_partition_desc` clause
- For a list partition, in the `table_partition_description` of the `list_partitions` clause
- For a system or reference partition, in the `table_partition_description` of the `reference_partition_desc` clause
- For the storage table of a nested table, in the `nested_table_col_properties` clause

 **See Also:**

*Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_COMPRESSION` package, which helps you choose the correct compression level for an application, and *Oracle Database Administrator's Guide* for more information about table compression, including examples

### Restrictions on Table Compression

Table compression is subject to the following restrictions:

- Data segments of BasicFiles LOBs are not compressed. For information on compression of SecureFiles LOBs, see `LOB_compression_clause`.
- You cannot drop a column from a table that uses `COMPRESS BASIC`, although you can set such a column as unused. All of the operations of the `ALTER TABLE ... drop_column_clause` are valid for tables that use `ROW STORE COMPRESS ADVANCED`, `COLUMN STORE COMPRESS FOR QUERY`, and `COLUMN STORE COMPRESS FOR ARCHIVE`.
- You cannot specify any type of table compression for an index-organized table, any overflow segment or partition of an overflow segment, or any mapping table segment of an index-organized table.
- You cannot specify any type of table compression for external tables or for tables that are part of a cluster.

- You cannot specify any type of table compression for tables with LONG or LONG RAW columns, tables that are owned by the SYS schema and reside in the SYSTEM tablespace, or tables with ROWDEPENDENCIES enabled.
- You cannot specify Hybrid Columnar Compression on tables that are enabled for flashback archiving.
- You cannot specify Hybrid Columnar Compression on the following object-relational features: object tables, XMLType tables, columns with abstract data types, collections stored as tables, or OPAQUE types, including XMLType columns stored as objects.
- When you update a row in a table compressed with Hybrid Columnar Compression, the ROWID of the row may change.
- In tables compressed with Hybrid Columnar Compression, updates to a single row may result in locks on multiple rows. Concurrency for write transactions may therefore be affected.
- If a table compressed with Hybrid Columnar Compression has a foreign key constraint, and you insert data using INSERT with the APPEND hint, then the data will be compressed to a lesser level than is typical with Hybrid Columnar Compression. To compress the data with Hybrid Columnar Compression, disable the foreign key constraint, insert the data using INSERT with the APPEND hint, and then reenable the foreign key constraint.

#### *inmemory\_table\_clause*

Use this clause to enable or disable the table for the In-Memory Column Store (IM column store). The IM column store is an optional, static SGA pool that stores copies of tables and partitions in a special columnar format optimized for rapid scans. The IM column store does not replace the buffer cache, but acts as a supplement so that both memory areas can store the same data in different formats.

- Specify INMEMORY to enable the table for the IM column store.

You can optionally use the *inmemory\_attributes* clause to specify how table data is stored in the IM column store. This clause enables you to specify the data compression method and the data population priority. In an Oracle RAC environment, it also enables you to specify how the data is distributed and duplicated across Oracle RAC instances. Refer to the *inmemory\_attributes* clause for more information.
- Specify NO INMEMORY to disable the table for the IM column store.
- Specify the *inmemory\_column\_clause* to enable or disable specific table columns for the IM column store, and to specify the data compression method for specific columns. Refer to the *inmemory\_clause* for more information.
- Specify INMEMORY ALL to mark all columns as in-memory. Specify NO INMEMORY ALL to mark all columns as not in-memory. These options are applied first to table columns.

You cannot specify INMEMORY ALL and NO INMEMORY ALL in the same DDL.

If you omit this clause, then the table is assigned the default IM column store settings for the tablespace in which it is created. Refer to the *inmemory\_clause* of CREATE TABLESPACE for more information on specifying the default IM column store settings for a tablespace.

In an Oracle Active Data Guard environment, if you specify this clause for a table on the primary database, then the table is enabled or disabled for the IM column store in the Oracle Active Data Guard instance.

 **Note:**

The `INMEMORY_CLAUSE_DEFAULT` initialization parameter enables you to specify a default IM column store clause for new tables and materialized views. Refer to *Oracle Database Reference* for more information on the `INMEMORY_CLAUSE_DEFAULT` initialization parameter.

### Restrictions on the In-Memory Column Store

The following restrictions apply to the In-Memory Column Store:

- You cannot specify the `INMEMORY` clause for index-organized tables.
- You cannot specify the `INMEMORY` clause for tables that are owned by the `SYS` schema and reside in the `SYSTEM` or `SYSAUX` tablespace.
- Starting with Oracle Database 18c , you can specify the `INMEMORY` clause for external tables. You must set the `QUERY_REWRITE_INTEGRITY` initialization parameter to `stale_tolerated` for the DDL to parse correctly. The policy may not be changed via `ALTER` to anything other than `stale_tolerated` if `INMEMORY` is specified.
- The IM column store does not support `LONG` or `LONG RAW` columns, out-of-line columns (LOBs, varrays, nested table columns), or extended data type columns. If you enable a table for the IM column store and it contains any of these types of columns, then the columns will not be populated in the IM column store.
- If you enable a table for the IM column store and it contains a virtual column, then the column will be populated in the IM column store only if the value of the `INMEMORY_VIRTUAL_COLUMNS` initialization parameter is `ENABLED` and the SQL expression for the virtual column refers only to columns that are enabled for the IM column store.

 **See Also:**

*Oracle Database In-Memory Guide* for an overview of the IM column store

### *inmemory\_attributes*

Use the `inmemory_memcompress`, `inmemory_priority`, `inmemory_distribute`, and `inmemory_duplicate` clauses to specify how table data is stored in the IM column store.

Specify the `inmemory_spatial` clause to apply inmemory attributes to spatial columns of type `SDO_GEOGRAPHY`.

### *inmemory\_memcompress*

Use this clause to specify the compression method for table data stored in the IM column store. This data is called In-Memory data.

To instruct the database to not compress In-Memory data, specify `NO MEMCOMPRESS`.

Specify MEMCOMPRESS AUTO to instruct the database to manage the segment including actions like evict, recompress, and populate.

To instruct the database to compress In-Memory data, specify MEMCOMPRESS FOR followed by one of the following methods:

- DML - This method is optimized for DML operations and performs little or no data compression.
- QUERY - Specifying QUERY is equivalent to specifying QUERY LOW.
- QUERY LOW - This method compresses In-Memory data the least (except for DML) and results in the best query performance. This is the default.
- QUERY HIGH - This method compresses In-Memory data more than QUERY LOW, but less than CAPACITY LOW.
- CAPACITY - Specifying CAPACITY is equivalent to specifying CAPACITY LOW.
- CAPACITY LOW - This method compresses In-Memory data more than QUERY HIGH, but less than CAPACITY HIGH, and results in excellent query performance.
- CAPACITY HIGH - This method compresses In-Memory data the most and results in good query performance.

Any memcompress level can be specified via DDL, but will be ignored during population. All In-Memory Compression Units (IMCUs) will be populated as QUERY LOW transparently.

#### *inmemory\_priority*

Use the PRIORITY clause to specify the data population priority for table data in the IM column store. This clause controls the priority of population, but not the speed of population.

- Specify NONE for **on-demand population**. In this case, the database populates table data in the IM column store when the table it is accessed through a full table scan. If the table is never accessed, or if it is accessed only through an index scan or fetch by rowid, then population never occurs. This is the default.
- Specify one of the following priority levels for **priority-based population**: LOW, MEDIUM, HIGH, or CRITICAL. In this case, the database automatically populates table data in the IM column store using an internally managed priority queue; a full scan is not a necessary condition for population. The database queues population of the table data based on the specified priority level. For example, a table with the setting INMEMORY PRIORITY CRITICAL takes precedence over a table with the setting INMEMORY PRIORITY HIGH, which in turn takes precedence over a table with the setting INMEMORY PRIORITY LOW, and so on. If the IM column store has insufficient space, then the database does not populate additional table data until space is available.

#### *inmemory\_distribute*

The DISTRIBUTE clause is applicable only if you are using Oracle Real Application Clusters (Oracle RAC) or Oracle Active Data Guard. It lets you specify how table data in the IM column store is distributed across Oracle RAC instances, and lets you specify the database instances in which the data is eligible to be populated.

#### AUTO and BY

Use the `AUTO` and `BY` clauses to specify how table data in the IM column store is distributed across Oracle RAC instances. You can specify the following options:

- `AUTO` - Oracle Database controls how data is distributed across Oracle RAC instances. Large tables are distributed across Oracle RAC instances depending on their access patterns. Smaller tables may be distributed between instances. This is the default.
- `BY ROWID RANGE` - Data in certain ranges of rowids is distributed to different Oracle RAC instances.
- `BY PARTITION` - Data in partitions is distributed to different Oracle RAC instances.
- `BY SUBPARTITION` - Data in subpartitions is distributed to different Oracle RAC instances.

You can only use `AUTO` and `BY` to distribute the In-Memory Compression Units (IMCUs) for an object between instances in a single Oracle RAC database, not between a primary instance and standby instance in Active Data Guard.

### FOR SERVICE

Use the `FOR SERVICE` clause to specify the Oracle RAC or Oracle Active Data Guard instances in which the object is eligible to be populated. You can specify the following options:

- `DEFAULT` - The object is eligible for population on all instances specified with the `PARALLEL_INSTANCE_GROUP` initialization parameter. If this parameter is not set, then the object is populated on all instances. This is the default.
- `ALL` - The object is eligible for population on all instances, regardless of the value of the `PARALLEL_INSTANCE_GROUP` initialization parameter.
- `service_name` - The object is eligible for population only on instances belonging to the specified service and only when the service is active and not blocked on an instance.
- `NONE` - The object is not eligible for population on any instances. This option lets you disable IM column store population while preserving the other In-Memory attributes for the table. These attributes take effect if you subsequently enable IM column store population for the table by specifying `FOR SERVICE DEFAULT`, `FOR SERVICE ALL`, or `FOR SERVICE service_name` in the `inmemory_distribute` clause of an `ALTER TABLE` statement.

In Oracle RAC, the `FOR SERVICE` clause specifies the instances within the Oracle RAC database. In Active Data Guard, the primary and standby databases may use a single-instance or Oracle RAC configuration. In Active Data Guard, the `FOR SERVICE` clause specifies instances in the primary database, instances in the standby database, or a mixture of primary and standby instances.

### *inmemory\_duplicate*

The `DUPLICATE` clause is applicable only if you are using Oracle Real Application Clusters (Oracle RAC) on an engineered system. It controls how table data in the IM column store is duplicated across Oracle RAC instances. You can specify the following options:

- `DUPLICATE` - Data is duplicated on one Oracle RAC instance, resulting in the data existing on a total of two Oracle RAC instances.
- `DUPLICATE ALL` - Data is duplicated across all Oracle RAC instances. If you specify `DUPLICATE ALL`, then the database uses the `DISTRIBUTE AUTO` setting, regardless of whether or how you specify the `inmemory_distribute` clause.
- `NO DUPLICATE` - Data is not duplicated across Oracle RAC instances. This is the default.

### *inmemory\_column\_clause*

Use this clause to enable or disable specific table columns for the IM column store, and to specify the data compression method for specific columns. If you specify this clause when creating a `NO INMEMORY` table, then the column settings will take effect when the table or partition is subsequently enabled for the IM column store.

- Specify `INMEMORY` to enable the specified table columns for the IM column store.

You can optionally use the `inmemory_memcompress` clause to specify the data compression method for specific columns. See [inmemory\\_memcompress](#). If you omit the `inmemory_memcompress` clause, then the table column uses the data compression method for the table. You cannot specify the `PRIORITY`, `DISTRIBUTE`, or `DUPLICATE` settings for a specific table column. These settings are the same for all table columns as they are for the table.

- Specify `NO INMEMORY` to disable the specified table columns for the IM column store.

If you omit the `inmemory_column_clause`, then all table columns use the IM column store settings for the table.

### **Restrictions on *inmemory\_column\_clause***

- You cannot specify this clause for a `LONG` or `LONG RAW` column, an out-of-line column (LOB, varray, nested table column), or an extended data type column.
- To selectively enable a virtual column for the IM column store, the value of the `INMEMORY_VIRTUAL_COLUMNS` initialization parameter must be `ENABLED` or `MANUAL`, and the SQL expression for the virtual column must refer only to columns that are enabled for the IM column store.

### *inmemory\_clause*

Use this clause to enable or disable a table partition for the IM column store. In order to specify this clause, the table must be enabled for the IM column store. If you omit this clause, then the table partition uses the IM column store settings for the table.

The `inmemory_attributes` clause has the same semantics for table partitions as for tables. Refer to the [inmemory\\_attributes](#) clause for full information.

### **INMEMORY TEXT**

Specify `INMEMORY TEXT` clause to enable IM full text columns. The `PRIORITY` clause has the same effect on population of IM full text columns as standard In-Memory columns. The default priority is `NONE`.

The `MEMCOMPRESS` clause is not valid with `INMEMORY TEXT`.

### **Examples**

```
CREATE TABLE mydoc(id NUMBER, docCreationTime DATE, doc CLOB, json_doc JSON)
INMEMORY TEXT(DOC, JSON_DOC)
```

```
CREATE TABLE mydoc(id NUMBER, docCreationTime DATE, doc CLOB, json_doc JSON)
INMEMORY PRIORITY CRITICAL
INMEMORY TEXT(DOC, JSON_DOC)
```

You can apply the `IMMEMORY TEXT` clause to search non-scalar columns in an In-Memory table. This clause enables fast In-Memory searching of text, XML, or JSON documents using the `CONTAINS()` or `JSON_TEXTCONTAINS()` operators.

`INMEMORY TEXT ( column_name1, column_name2 )` specifies the list of columns to be enabled as IM full text. The columns must be of type `CHAR`, `VARCHAR2`, `CLOB`, `BLOB`, or `JSON`. `JSON` columns have `JSON_TEXTCONTAINS()` automatically enabled.

`INMEMORY TEXT ( column_name1 USING policy1, column_name2 USING policy2 )` specifies the list of columns to be enabled as IM full text along with custom indexing policies. The columns must be of type `CHAR`, `VARCHAR2`, `CLOB`, or `BLOB`. You cannot use this clause with columns of type `JSON`.

You can use the `IMMEMORY PRIORITY` clause to set the order in which objects are populated.

 **See Also:**

[IM Full Text Columns](#).

You can specify `INMEMORY` on non-partitioned tables using the `ORACLE_HIVE`, `ORACLE_HDFS`, and `ORACLE_BIGDATA` driver types.

***ilm\_clause***

Use this clause to add an Automatic Data Optimization policy to `table`.

This clause has the same semantics in `CREATE TABLE` and `ALTER TABLE`, with the following additional restriction: You can specify only the `ADD POLICY` clause for `CREATE TABLE`. Refer to the [`ilm\_clause`](#) for the full semantics of this clause.

 **See Also:**

[Oracle Database VLDB and Partitioning Guide](#) for more information on managing policies for Automatic Data Optimization

**Restrictions on Automatic Data Optimization**

Automatic Data Optimization is subject to the following restrictions:

- Automatic Data Optimization is not supported for tables that contain object types, index-organized tables, clustered tables, or materialized views.
- Row-level policies are not supported for tables that support Temporal Validity or tables that are enabled for row archiving for In-Database Archiving.

***ilm\_policy\_clause***

Use this clause to describe the Automatic Data Optimization policy.

This clause has the same semantics in `CREATE TABLE` and `ALTER TABLE`. Refer to [`ilm\_policy\_clause`](#) for the full semantics of this clause.

## RECOVERABLE | UNRECOVERABLE

These keywords are deprecated and have been replaced with LOGGING and NOLOGGING, respectively. Although RECOVERABLE and UNRECOVERABLE are supported for backward compatibility, Oracle strongly recommends that you use the LOGGING and NOLOGGING keywords.

### Restrictions on [UN]RECOVERABLE

This clause is subject to the following restrictions:

- You cannot specify RECOVERABLE for partitioned tables or LOB storage characteristics.
- You cannot specify UNRECOVERABLE for partitioned or index-organized tables.
- You can specify UNRECOVERABLE only with AS *subquery*.

## ORGANIZATION

The ORGANIZATION clause lets you specify the order in which the data rows of the table are stored.

### HEAP

HEAP indicates that the data rows of *table* are stored in no particular order. This is the default.

### INDEX

INDEX indicates that *table* is created as an index-organized table. In an index-organized table, the data rows are held in an index defined on the primary key for the table.

### EXTERNAL

EXTERNAL indicates that table is a read-only table located outside the database.

#### See Also:

["External Table Example"](#)

## *index\_org\_table\_clause*

Use the *index\_org\_table\_clause* to create an index-organized table. Oracle Database maintains the table rows, both primary key column values and nonkey column values, in an index built on the primary key. Index-organized tables are therefore best suited for primary key-based access and manipulation. An index-organized table is an alternative to:

- A noncluster table indexed on the primary key by using the CREATE INDEX statement
- A cluster table stored in an indexed cluster that has been created using the CREATE CLUSTER statement that maps the primary key for the table to the cluster key

You must specify a primary key for an index-organized table, because the primary key uniquely identifies a row. The primary key cannot be DEFERRABLE. Use the primary key instead of the rowid for directly accessing index-organized rows.

If an index-organized table is partitioned and contains LOB columns, then you should specify the `index_org_table_clause` first, then the `LOB_storage_clause`, and then the appropriate `table_partitioning_clauses`.

You cannot use the `TO_LOB` function to convert a `LONG` column to a LOB column in the subquery of a `CREATE TABLE ... AS SELECT` statement if you are creating an index-organized table. Instead, create the index-organized table without the `LONG` column, and then use the `TO_LOB` function in an `INSERT ... AS SELECT` statement.

The `ROWID` pseudocolumn of an index-organized table returns logical rowids instead of physical rowids. A column that you create with the data type `ROWID` cannot store the logical rowids of the IOT. The only data you can store in a column of type `ROWID` is rowids from heap-organized tables. If you want to store the logical rowids of an IOT, then create a column of type `UROWID` instead. A column of type `UROWID` can store both physical and logical rowids.

#### See Also:

["Index-Organized Table Example"](#)

### Restrictions on Index-Organized Tables

Index-organized tables are subject to the following restrictions:

- You cannot define a virtual column for an index-organized table.
- You cannot specify the `composite_range_partitions`, `composite_list_partitions`, or `composite_hash_partitions` clauses for an index-organized table.
- If the index-organized table is a nested table or varray, then you cannot specify `table_partitioning_clauses`.
- The collations of character data type columns belonging to the primary key of an index-organized table must be `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.

### **PCTTHRESHOLD integer**

Specify the percentage of space reserved in the index block for an index-organized table row. `PCTTHRESHOLD` must be large enough to hold the primary key. All trailing columns of a row, starting with the column that causes the specified threshold to be exceeded, are stored in the overflow segment. `PCTTHRESHOLD` must be a value from 1 to 50. If you do not specify `PCTTHRESHOLD`, then the default is 50.

### **Restriction on PCTTHRESHOLD**

You cannot specify `PCTTHRESHOLD` for individual partitions of an index-organized table.

### ***mapping\_table\_clauses***

Specify `MAPPING TABLE` to instruct the database to create a mapping of local to physical `ROWIDS` and store them in a heap-organized table. This mapping is needed in order to create a bitmap index on the index-organized table. If the index-organized table is partitioned, then

the mapping table is also partitioned and its partitions have the same name and physical attributes as the base table partitions.

Oracle Database creates the mapping table or mapping table partition in the same tablespace as its parent index-organized table or partition. You cannot query, perform DML operations on, or modify the storage characteristics of the mapping table or its partitions.

#### *prefix\_compression*

The *prefix\_compression* clauses let you enable or disable prefix compression for index-organized tables.

- Specify `COMPRESS` to enable **prefix compression**, also known as key compression, for an index-organized table, which eliminates repeated occurrence of primary key column values in index-organized tables. Use *integer* to specify the prefix length, which is the number of prefix columns to compress.

The valid range of prefix length values is from 1 to the number of primary key columns minus 1. The default prefix length is the number of primary key columns minus 1.

- Specify `NOCOMPRESS` to disable prefix compression in index-organized tables. This is the default.

#### **Restriction on Prefix Compression of Index-organized Tables**

At the partition level, you can specify `COMPRESS`, but you cannot specify the prefix length with *integer*.

#### *iot\_advanced\_compression*

Specify *iot\_advanced\_compression* to compress the indexes of index organized tables (IOTs) and table partitions in order to reduce the storage footprint of IOTs.

You can enable advanced low index compression for all IOTs on specific partitions of a table, and leave other partitions uncompressed.

#### *index\_org\_overflow\_clause*

The *index\_org\_overflow\_clause* lets you instruct the database that index-organized table data rows exceeding the specified threshold are placed in the data segment specified in this clause.

- When you create an index-organized table, Oracle Database evaluates the maximum size of each column to estimate the largest possible row. If an overflow segment is needed but you have not specified `OVERFLOW`, then the database raises an error and does not execute the `CREATE TABLE` statement. This checking function guarantees that subsequent DML operations on the index-organized table will not fail because an overflow segment is lacking.
- All physical attributes and storage characteristics you specify in this clause after the `OVERFLOW` keyword apply only to the overflow segment of the table. Physical attributes and storage characteristics for the index-organized table itself, default values for all its partitions, and values for individual partitions must be specified before this keyword.

- If the index-organized table contains one or more LOB columns, then the LOBs will be stored out-of-line unless you specify `OVERFLOW`, even if they would otherwise be small enough to be stored inline.
- If `table` is partitioned, then the database equipartitions the overflow data segments with the primary key index segments.

#### **INCLUDING *column\_name***

Specify a column at which to divide an index-organized table row into index and overflow portions. The primary key columns are always stored in the index. `column_name` can be either the last primary key column or any non primary key column. All non primary key columns that follow `column_name` are stored in the overflow data segment.

If an attempt to divide a row at `column_name` causes the size of the index portion of the row to exceed the specified or default `PCTTHRESHOLD` value, then the database breaks up the row based on the `PCTTHRESHOLD` value.

#### **Restriction on the INCLUDING Clause**

You cannot specify this clause for individual partitions of an index-organized table.

#### **EXTERNAL PARTITION ATTRIBUTES**

Use the **EXTERNAL PARTITION ATTRIBUTES** clause to specify table level external parameters in a hybrid partitioned table.

#### ***external\_table\_clause***

Use the `external_table_clause` to create an external table, which allows you to process data that is stored outside the database from within the database without loading any of the data into the database.

Defining an external table only creates metadata in the data dictionary, pointing to data outside the database and providing seamless read only access to such data.

Because external tables have no data in the database, you define them with a small subset of the clauses normally available when creating tables.

In addition to supporting external data residing in operating file systems and Big Data sources and formats such as HDFS and Hive, Oracle supports external data residing in objects via the `DBMS_CLOUD` package.

You can work with data in object stores using the `DBMS_CLOUD` package or by manually defining external tables. Oracle strongly recommends using `DBMS_CLOUD` for the additional functionality that is fully compatible with Oracle autonomous database.

#### **See Also:**

- `DBMS_CLOUD`
- *Managing External Tables*

- Within the `relational_properties` clause, you can specify only `column`, `datatype`, `ENCRYPT`, `inline_constraint`, and `out_of_line_constraint`. You can specify the `ENCRYPT` clause only when you specify the `ORACLE_DATAPUMP` access driver and the `AS`

*subquery clause* to load data into the external table. Within the *inline\_constraint* and *out\_of\_line\_constraint* clauses, you can specify all subclauses except *CHECK*.

- Within the *physical\_properties\_clause*, you can specify only the organization of the table (*ORGANIZATION EXTERNAL external\_table\_clause*).
- Within the *table\_properties\_clause*, you can specify the *parallel\_clause*. The *parallel\_clause* lets you parallelize subsequent queries on the external data and subsequent operations that populate the external table.

Starting with Oracle Database 12c Release 2 (12.2), you can create a **partitioned external table**. To do this, within the *table\_properties\_clause*, you can specify the following subclauses of the *table\_partitioning\_clauses*:

- *range\_partitions* - specify this clause to create a range-partitioned or interval-partitioned external table
- *list\_partitions* - specify this clause to create a list-partitioned external table. Within this clause, you cannot specify the *AUTOMATIC* clause; an automatic list-partitioned table cannot be an external table.
- *composite\_range\_partitions* - specify this clause to create a range-range, range-list, interval-range, or interval-list composite-partitioned external table
- *composite\_list\_partitions* - specify this clause to create a list-range or list-list composite-partitioned external table. Within this clause, you cannot specify the *AUTOMATIC* clause; an automatic composite-partitioned table cannot be an external table.
- You can populate the external table at create time by using the *AS subquery* clause.

No other clauses are permitted in the same `CREATE TABLE` statement.

#### See Also:

- "[External Table Example](#)"
- `ALTER TABLE ... "PROJECT COLUMN Clause"` for information on the effect of changing the default property of the column projection
- *Oracle Database Data Warehousing Guide*, *Oracle Database Administrator's Guide*, and *Oracle Database Utilities* for information on the uses for external tables

## Restrictions on External Tables

External tables are subject to the following restrictions:

- An external table cannot be a temporary table.
- You can specify only the following types of constraints on an external table: *NOT NULL* constraints, unique constraints, primary key constraints, and foreign key constraints. When you specify unique constraints, primary key constraints, or foreign key constraints, you must also specify *RELY DISABLE*. These constraints are declarative and are not enforced. They can increase query performance and

reduce resource consumption because more optimizer transformations can be taken into account. In order for the optimizer to utilize these `RELY DISABLE` constraints, the `QUERY_REWRITE_INTEGRITY` initialization parameter must be set to either `trusted` or `stale_tolerated`.

- You cannot create an index on an external table.
- An external table cannot contain `INVISIBLE` columns.
- An external table cannot have object type, varray, or `LONG` columns. However, you can populate LOB columns of an external table with varray or `LONG` data from an internal database table.
- Only `ORACLE_LOADER` and `ORACLE_DATAPUMP` access types are permitted for external tables that can be populated into the inmemory column store.

#### TYPE

`TYPE access_driver_type` indicates the **access driver** of the external table. The access driver is the API that interprets the external data for the database. Oracle Database provides the following access drivers: `ORACLE_LOADER`, `ORACLE_DATAPUMP`, `ORACLE_HDFS`, and `ORACLE_HIVE`. If you do not specify `TYPE`, then the database uses `ORACLE_LOADER` as the default access driver. You must specify the `ORACLE_DATAPUMP` access driver if you specify the `AS subquery` clause to unload data from one Oracle Database and reload it into the same or a different Oracle Database.

#### See Also:

*Oracle Database Utilities* for information about the `ORACLE_LOADER`, `ORACLE_DATAPUMP`, `ORACLE_HDFS`, and `ORACLE_HIVE` access drivers

#### DEFAULT DIRECTORY

`DEFAULT DIRECTORY` lets you specify a default directory object corresponding to a directory on the file system where the external data sources may reside. The default directory can also be used by the access driver to store auxiliary files such as error logs.

#### ACCESS PARAMETERS

The optional `ACCESS PARAMETERS` clause lets you assign values to the parameters of the specific access driver for this external table.

- The `opaque_format_spec` specifies all access parameters for the `ORACLE_LOADER`, `ORACLE_DATAPUMP`, `ORACLE_HDFS`, and `ORACLE_HIVE` access drivers. See *Oracle Database Utilities* for descriptions of the `ORACLE_LOADER`, `ORACLE_DATAPUMP`, `ORACLE_HDFS`, and `ORACLE_HIVE` access parameters.

Field names specified in the `opaque_format_spec` must match columns in the table definition. Oracle Database ignores any field in the `opaque_format_spec` that is not matched by a column in the table definition.

- `USING CLOB subquery` lets you derive the parameters and their values through a subquery. The subquery cannot contain any set operators or an `ORDER BY` clause. It must return one row containing a single item of data type `CLOB`.

Whether you specify the parameters in an *opaque\_format\_spec* or derive them using a subquery, the database does not interpret anything in this clause. It is up to the access driver to interpret this information in the context of the external data.

For inline external tables and external modify query statements you must use *opaque\_format\_spec* within single quotes. For DDL statements you must use *opaque\_format\_spec* without single quotes.

## LOCATION

The `LOCATION` clause lets you specify one or more external data sources. Usually the `locationSpecifier` is a file, but it need not be. Oracle Database does not interpret this clause. It is up to the access driver to interpret this information in the context of the external data.

You must specify the `LOCATION` clause as follows:

- When creating a nonpartitioned external table, you must specify the `LOCATION` clause at the table level in the `externalTableDataProps` clause.
- When creating a partitioned external table, you must specify the `LOCATION` clause at the partition level in the `externalPartSubpartDataProps` clause.
- When creating a composite-partitioned external table, you must specify the `LOCATION` clause at the subpartition level in the `externalPartSubpartDataProps` clause.

## REJECT LIMIT

The `REJECT LIMIT` clause lets you specify how many conversion errors can occur during a query of the external data before an Oracle Database error is returned and the query is aborted. The default value is 0.

## CLUSTER Clause

The `CLUSTER` clause indicates that the table is to be part of `cluster`. The columns listed in this clause are the table columns that correspond to the cluster columns. Generally, the cluster columns of a table are the column or columns that make up its primary key or a portion of its primary key. Refer to [CREATE CLUSTER](#) for more information.

Specify one column from the table for each column in the cluster key. The columns are matched by position, not by name.

A cluster table uses the space allocation of the cluster. Therefore, do not use the `PCTFREE`, `PCTUSED`, or `INITTRANS` parameters, the `TABLESPACE` clause, or the `storageClause` with the `CLUSTER` clause.

## Restrictions on Cluster Tables

Cluster tables are subject to the following restrictions:

- Object tables and tables containing LOB columns or columns of the `Any*` Oracle-supplied types cannot be part of a cluster.
- You cannot specify the `parallelClause` or `CACHE` or `NOCACHE` for a table that is part of a cluster.

- You cannot specify CLUSTER with either ROWDEPENDENCIES or NOROWDEPENDENCIES unless the cluster has been created with the same ROWDEPENDENCIES or NOROWDEPENDENCIES setting.
- A cluster table cannot contain INVISIBLE columns.

### ***table\_properties***

The *table\_properties* further define the characteristics of the table.

### ***column\_properties***

Use the *column\_properties* clauses to specify the storage attributes of a column.

#### ***object\_type\_col\_properties***

The *object\_type\_col\_properties* determine storage characteristics of an object column or attribute or of an element of a collection column or attribute.

##### ***column***

For *column*, specify an object column or attribute.

##### ***substitutable\_column\_clause***

The *substitutable\_column\_clause* indicates whether object columns or attributes in the same hierarchy are substitutable for each other. You can specify that a column is of a particular type, or whether it can contain instances of its subtypes, or both.

- If you specify ELEMENT, then you constrain the element type of a collection column or attribute to a subtype of its declared type.
- The IS OF [TYPE] (ONLY *type*) clause constrains the type of the object column to a subtype of its declared type.
- NOT SUBSTITUTABLE AT ALL LEVELS indicates that the object column cannot hold instances corresponding to any of its subtypes. Also, substitution is disabled for any embedded object attributes and elements of embedded nested tables and varrays. The default is SUBSTITUTABLE AT ALL LEVELS.

##### **Restrictions on the *substitutable\_column\_clause***

This clause is subject to the following restrictions:

- You cannot specify this clause for an attribute of an object column. However, you can specify this clause for a object type column of a relational table and for an object column of an object table if the substitutability of the object table itself has not been set.
- For a collection type column, the only part of this clause you can specify is [NOT] SUBSTITUTABLE AT ALL LEVELS.

### ***LOB\_storage\_clause***

The *LOB\_storage\_clause* lets you specify the storage attributes of LOB data segments. You must specify at least one clause after the STORE AS keywords. If you specify more than one clause, then you must specify them in the order shown in the syntax diagram, from top to bottom.

For a nonpartitioned table, this clause specifies the storage attributes of LOB data segments of the table.

For a partitioned table, Oracle Database implements this clause depending on where it is specified:

- For a partitioned table specified at the table level—when specified in the *physical\_properties* clause along with one of the partitioning clauses—this clause specifies the default storage attributes for LOB data segments associated with each partition or subpartition. These storage attributes apply to all partitions or subpartitions unless overridden by a *LOB\_storage\_clause* at the partition or subpartition level.
- For an individual partition of a partitioned table—when specified as part of a *table\_partition\_description*—this clause specifies the storage attributes of the data segments of the partition or the default storage attributes of any subpartitions of the partition. A partition-level *LOB\_storage\_clause* overrides a table-level *LOB\_storage\_clause*.
- For an individual subpartition of a partitioned table—when specified as part of *subpartition\_by\_hash* or *subpartition\_by\_list*—this clause specifies the storage attributes of the data segments of the subpartition. A subpartition-level *LOB\_storage\_clause* overrides both partition-level and table-level *LOB\_storage\_clauses*.

**Restriction on the *LOB\_storage\_clause*:**

Only the `TABLESPACE` clause is allowed when specifying the *LOB\_storage\_clause* in a subpartition.

 **See Also:**

- [Oracle Database SecureFiles and Large Objects Developer's Guide](#) for detailed information about LOBs, including guidelines for creating gigabyte LOBs
- ["Creating a Table: LOB Column Example"](#)

***LOB\_item***

Specify the LOB column name or LOB object attribute for which you are explicitly defining tablespace and storage characteristics that are different from those of the table. Oracle Database automatically creates a system-managed index for each *LOB\_item* you create.

**SECUREFILE | BASICFILE**

Use this clause to specify the type of LOB storage, either high-performance LOB (SecureFiles), or the traditional LOB (BasicFiles).

 **See Also:**

- [Oracle Database SecureFiles and Large Objects Developer's Guide](#) for more information about SecureFiles LOBs

 **Note:**

You cannot convert a LOB from one type of storage to the other. Instead you must migrate to SecureFiles or BasicFiles by using online redefinition or partition exchange.

***LOB\_segname***

Specify the name of the LOB data segment. You cannot use *LOB\_segname* if you specify more than one *LOB\_item*.

***LOB\_storage\_parameters***

The *LOB\_storage\_parameters* clause lets you specify various elements of LOB storage.

**TABLESPACE Clause**

Use this clause to specify the tablespace in which LOB data is to be stored.

**TABLESPACE SET Clause**

This clause is valid only when creating a sharded table by specifying the SHARDED keyword of CREATE TABLE. Use this clause to specify the tablespace set in which LOB data is to be stored.

***storage\_clause***

Use the *storage\_clause* to specify various aspects of LOB segment storage. Of particular interest in the context of LOB storage is the MAXSIZE clause of the *storage\_clause*, which can be used in combination with the *LOB\_retention\_clause* of *LOB\_parameters*. Refer to [storage\\_clause](#) for more information.

***LOB\_parameters***

Several of the *LOB\_parameters* are no longer needed if you are using SecureFiles for LOB storage. The PCTVERSION and FREEPOOLS parameters are valid and useful only if you are using BasicFiles LOB storage.

**ENABLE STORAGE IN ROW**

If you enable storage in row, then the LOB value is stored in the row (inline) if its length is less than approximately 4000 bytes minus system control information. This is the default.

**Restriction on Enabling Storage in Row**

For an index-organized table, you cannot specify this parameter unless you have specified an OVERFLOW segment in the *index\_org\_table\_clause*.

**DISABLE STORAGE IN ROW**

If you disable storage in row, then the LOB value is stored outside of the row out of line regardless of the length of the LOB value.

The LOB locator is always stored inline regardless of where the LOB value is stored. You cannot change the value of STORAGE IN ROW once it is set except by moving the table. See the [move\\_table\\_clause](#) in the ALTER TABLE documentation for more information.

**CHUNK *integer***

Specify the number of bytes to be allocated for LOB manipulation. If *integer* is not a multiple of the database block size, then the database rounds up in bytes to the next multiple. For example, if the database block size is 2048 and *integer* is 2050, then the database allocates 4096 bytes (2 blocks). The maximum value is 32768 (32K), which is the largest Oracle Database block size allowed. The default CHUNK size is one Oracle Database block.

The value of CHUNK must be less than or equal to the value of NEXT, either the default value or that specified in the *storage\_clause*. If CHUNK exceeds the value of NEXT, then the database returns an error. You cannot change the value of CHUNK once it is set.

**PCTVERSION *integer***

Specify the maximum percentage of overall LOB storage space used for maintaining old versions of the LOB. If the database is running in manual undo mode, then the default value is 10, meaning that older versions of the LOB data are not overwritten until they consume 10% of the overall LOB storage space.

You can specify the PCTVERSION parameter whether the database is running in manual or automatic undo mode. PCTVERSION is the default in manual undo mode. RETENTION is the default in automatic undo mode. You cannot specify both PCTVERSION and RETENTION.

This clause is not valid if you have specified SECUREFILE. If you specify both SECUREFILE and PCTVERSION, then the database silently ignores the PCTVERSION parameter.

**LOB\_retention\_clause**

Use this clause to specify whether you want the LOB segment retained for flashback purposes, consistent-read purposes, both, or neither.

You can specify the RETENTION parameter only if the database is running in automatic undo mode. Oracle Database uses the value of the UNDO\_RETENTION initialization parameter to determine the amount of committed undo data to retain in the database. In automatic undo mode, RETENTION is the default value unless you specify PCTVERSION. You cannot specify both PCTVERSION and RETENTION.

You can specify the optional settings after RETENTION only if you are using SecureFiles. The SECUREFILE parameter of the *LOB\_storage\_clause* indicates that the database will use SecureFiles to manage storage dynamically, taking into account factors such as the undo mode of the database.

- Specify MAX to signify that the undo should be retained until the LOB segment has reached MAXSIZE. If you specify MAX, then you must also specify the MAXSIZE clause in the *storage\_clause*.
- Specify MIN if the database is in flashback mode to limit the undo retention duration for the specific LOB segment to *n* seconds.
- Specify AUTO if you want to retain undo sufficient for consistent read purposes only.
- Specify NONE if no undo is required for either consistent read or flashback purposes.

If you do not specify the `RETENTION` parameter, or you specify `RETENTION` with no optional settings, then `RETENTION` is set to `DEFAULT`, which is functionally equivalent to `AUTO`.

#### See Also:

- To set the `UNDO_RETENTION` initialization parameter, see Setting the Minimum Undo Retention Period
- `CREATE TABLE` clause [`LOB\_storage\_parameters`](#) for more information on simplified LOB storage using SecureFiles
- *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information on using SecureFiles
- [`flashback\_mode\_clause`](#) of `ALTER DATABASE` for information on putting a database in flashback mode
- "[Creating an Undo Tablespace: Example](#)"

### **FREEPOOLS *integer***

Specify the number of groups of free lists for the LOB segment. Normally *integer* will be the number of instances in an Oracle Real Application Clusters environment or 1 for a single-instance database.

You can specify this parameter only if the database is running in automatic undo mode. In this mode, `FREEPOOLS` is the default unless you specify the `FREELIST GROUPS` parameter of the `storage_clause`. If you specify neither `FREEPOOLS` nor `FREELIST GROUPS`, then the database uses a default of `FREEPOOLS 1` if the database is in automatic undo management mode and a default of `FREELIST GROUPS 1` if the database is in manual undo management mode.

This clause is not valid if you have specified `SECUREFILE`. If you specify both `SECUREFILE` and `FREEPOOLS`, then the database silently ignores the `FREEPOOLS` parameter.

#### **Restriction on FREEPOOLS**

You cannot specify both `FREEPOOLS` and the `FREELIST GROUPS` parameter of the `storage_clause`.

#### **`LOB_deduplicate_clause`**

This clause is valid only for SecureFiles LOBs. Use the `LOB_deduplicate_clause` to enable or disable LOB deduplication, which is the elimination of duplicate LOB data.

The `DEDUPLICATE` keyword instructs the database to eliminate duplicate copies of LOBs. Using a secure hash index to detect duplication, the database coalesces LOBs with identical content into a single copy, reducing storage consumption and simplifying storage management.

If you omit this clause, then LOB deduplication is disabled by default.

This clause implements LOB deduplication for the entire LOB segment. To enable or disable deduplication for an individual LOB, use the `DBMS_LOB.SETOPTIONS` procedure.

 **See Also:**

*Oracle Database SecureFiles and Large Objects Developer's Guide* for more information about LOB deduplication and *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_LOB` package

***LOB\_compression\_clause***

This clause is valid only for SecureFiles LOBs, not for BasicFiles LOBs. Use the `LOB_compression_clause` to instruct the database to enable or disable server-side LOB compression. Random read/write access is possible on server-side compressed LOB segments. LOB compression is independent from table compression or index compression. If you omit this clause, then the default is `NOCOMPRESS`.

You can specify `HIGH`, `MEDIUM`, or `LOW` to vary the degree of compression. The `HIGH` degree of compression incurs higher latency than `MEDIUM` but provides better compression. The `LOW` degree results in significantly higher decompression and compression speeds, at the cost of slightly lower compression ratio than either `HIGH` or `MEDIUM`. If you omit this optional parameter, then the default is `MEDIUM`.

This clause implements server-side LOB compression for the entire LOB segment. To enable or disable compression on an individual LOB, use the `DBMS_LOB.SETOPTIONS` procedure.

 **See Also:**

*Oracle Database SecureFiles and Large Objects Developer's Guide* for more information on server-side LOB storage and *Oracle Database PL/SQL Packages and Types Reference* for information about client-side LOB compression using the `UTL_COMPRESS` supplied package and for information about the `DBMS_LOB` package

**ENCRYPT | DECRYPT**

These clauses are valid only for LOBs that are using SecureFiles for LOB storage. Specify `ENCRYPT` to encrypt all LOBs in the column. Specify `DECRYPT` to keep the LOB in cleartext. If you omit this clause, then `DECRYPT` is the default.

Refer to `encryption_spec` for general information on that clause. When applied to a LOB column, `encryption_spec` is specific to the individual LOB column, so the encryption algorithm can differ from that of other LOB columns and other non-LOB columns. Use the `encryption_spec` as part of the `column_definition` to encrypt the entire LOB column. Use the `encryption_spec` as part of the `LOB_storage_clause` in the `table_partition_description` to encrypt a LOB partition.

**Restriction on `encryption_spec` for LOBs**

You cannot specify the `SALT` or `NO SALT` clauses of `encryption_spec` for LOB encryption.

 **See Also:**

*Oracle Database SecureFiles and Large Objects Developer's Guide* for more information on LOB encryption and *Oracle Database PL/SQL Packages and Types Reference* for information the DBMS\_LOB package

**CACHE | NOCACHE | CACHE READS**

Refer to [CACHE | NOCACHE | CACHE READS](#) for information on these clauses.

**LOB\_partition\_storage**

The *LOB\_partition\_storage* clause lets you specify a separate *LOB\_storage\_clause* or *varray\_col\_properties* clause for each partition. You must specify the partitions in the order of partition position. You can find the order of the partitions by querying the PARTITION\_NAME and PARTITION\_POSITION columns of the USER\_IND\_PARTITIONS view.

If you do not specify a *LOB\_storage\_clause* or *varray\_col\_properties* clause for a particular partition, then the storage characteristics are those specified for the LOB item at the table level. If you also did not specify any storage characteristics for the LOB item at the table level, then Oracle Database stores the LOB data partition in the same tablespace as the table partition to which it corresponds.

**Restrictions on *LOB\_partition\_storage***

*LOB\_partition\_storage* is subject to the following restrictions:

- In the *LOB\_parameters* of the *LOB\_storage\_clause*, you cannot specify *encryption\_spec*, because it is invalid to specify an encryption algorithm for partitions and subpartitions.
- You can only specify the *TABLESPACE* clause for hash partitions and all types of subpartitions.

**varray\_col\_properties**

The *varray\_col\_properties* let you specify separate storage characteristics for the LOB in which a varray will be stored. If *varray\_item* is a multilevel collection, then the database stores all collection items nested within *varray\_item* in the same LOB in which *varray\_item* is stored.

- For a nonpartitioned table—when specified in the *physical\_properties* clause without any of the partitioning clauses—this clause specifies the storage attributes of the LOB data segments of the varray.
- For a partitioned table specified at the table level—when specified in the *physical\_properties* clause along with one of the partitioning clauses—this clause specifies the default storage attributes for the varray LOB data segments associated with each partition (or its subpartitions, if any).
- For an individual partition of a partitioned table—when specified as part of a *table\_partition\_description*—this clause specifies the storage attributes of the varray LOB data segments of that partition or the default storage attributes of the varray LOB data segments of any subpartitions of this partition. A partition-level *varray\_col\_properties* overrides a table-level *varray\_col\_properties*.

- For an individual subpartition of a partitioned table—when specified as part of `subpartition_by_hash` or `subpartition_by_list`—this clause specifies the storage attributes of the varray data segments of this subpartition. A subpartition-level `varray_col_properties` overrides both partition-level and table-level `varray_col_properties`.

### STORE AS [SECUREFILE | BASICFILE] LOB Clause

If you specify `STORE AS LOB`, then:

- If the maximum varray size is less than approximately 4000 bytes, then the database stores the varray as an inline LOB unless you have disabled storage in row.
- If the maximum varray size is greater than approximately 4000 bytes or if you have disabled storage in row, then the database stores in the varray as an out-of-line LOB.

If you do not specify `STORE AS LOB`, then storage is based on the maximum possible size of the varray rather than on the actual size of a varray column. The maximum size of the varray is the number of elements times the element size, plus a small amount for system control information. If you omit this clause, then:

- If the maximum size of the varray is less than approximately 4000 bytes, then the database does not store the varray as a LOB, but as inline data.
- If the maximum size is greater than approximately 4000 bytes, then the database always stores the varray as a LOB.
  - If the actual size is less than approximately 4000 bytes, then it is stored as an inline LOB
  - If the actual size is greater than approximately 4000 bytes, then it is stored as an out-of-line LOB, as is true for other LOB columns.

### `substitutable_column_clause`

The `substitutable_column_clause` has the same behavior as described for `object_type_col_properties`.

#### See Also:

["Substitutable Table and Column Examples"](#)

### Restriction on Varray Column Properties

You cannot specify this clause on an interval partitioned table.

### `nested_table_col_properties`

The `nested_table_col_properties` let you specify separate storage characteristics for a nested table, which in turn enables you to define the nested table as an index-organized table. Unless you explicitly specify otherwise in this clause:

- For a nonpartitioned table, the storage table is created in the same schema and the same tablespace as the parent table.

- For a partitioned table, the storage table is created in the default tablespace of the schema. By default, nested tables are equipartitioned with the partitioned base table.
- In either case, the storage table uses default storage characteristics, and stores the nested table values of the column for which it was created.

You must include this clause when creating a table with columns or column attributes whose type is a nested table. Clauses within *nested\_table\_col\_properties* that function the same way they function for the parent table are not repeated here.

#### ***nested\_item***

Specify the name of a column, or of a top-level attribute of the object type of the tables, whose type is a nested table.

#### **COLUMN\_VALUE**

If the nested table is a multilevel collection, then the inner nested table or varray may not have a name. In this case, specify COLUMN\_VALUE in place of the *nested\_item* name.

#### **See Also:**

"[Creating a Table: Multilevel Collection Example](#)" for examples using *nested\_item* and COLUMN\_VALUE

#### **LOCAL | GLOBAL**

Specify LOCAL to equipartition the nested table with the base table. This is the default. Oracle Database automatically creates a local partitioned index for the partitioned nested table.

Specify GLOBAL to indicate that the nested table is a nonpartitioned nested table of a partitioned base table.

#### ***storage\_table***

Specify the name of the table where the rows of *nested\_item* reside.

You cannot query or perform DML statements on *storage\_table* directly, but you can modify its storage characteristics by specifying its name in an ALTER TABLE statement.

#### **See Also:**

[ALTER TABLE](#) for information about modifying nested table column storage characteristics

#### **RETURN [AS]**

Specify what Oracle Database returns as the result of a query.

- VALUE returns a copy of the nested table itself.
- LOCATOR returns a collection locator to the copy of the nested table.

The locator is scoped to the session and cannot be used across sessions. Unlike a LOB locator, the collection locator cannot be used to modify the collection instance.

If you do not specify the `segment_attributes_clause` or the `LOB_storage_clause`, then the nested table is heap organized and is created with default storage characteristics.

### Restrictions on Nested Table Column Properties

Nested table column properties are subject to the following restrictions:

- You cannot specify this clause for a temporary table.
- You cannot specify this clause on an interval partitioned table.
- You cannot specify the `oid_clause`.
- At create time, you cannot use `object_properties` to specify an `out_of_line_ref_constraint`, `inline_ref_constraint`, or foreign key constraint for the attributes of a nested table.

#### See Also:

- [ALTER TABLE](#) for information about modifying nested table column storage characteristics
- ["Nested Table Example"](#) and ["Creating a Table: Multilevel Collection Example"](#)

### `XMLType_column_properties`

The `XMLType_column_properties` let you specify storage attributes for an XMLTYPE column.

### `XMLType_storage`

XMLType tables and columns data can be stored as transportable binary XML, binary XML, or a set of objects in object-relational storage.

- Specify `TRANSPORTABLE BINARY XML` to store XML data in a transportable format that is scalable and distributed. See [Create Tables and Columns as Transportable Binary XML](#) for examples.
  - `TRANSPORTABLE BINARY XML` can only be stored in `SECUREFILE`.
  - Any LOB parameters you specify are applied to the underlying `BLOB` column created for storing the transportable binary XML encoded value. .
  - You can not specify the `XMLSchema_spec` clause for `TRANSPORTABLE BINARY XML`.
- Specify `BINARY XML` to store the XML data in compact binary XML format.

Any LOB parameters you specify are applied to the underlying `BLOB` column created for storing the binary XML encoded value.

In earlier releases, binary XML data is stored by default in a BasicFiles LOB. Beginning with Oracle Database 11g Release 2 (11.2.0.2), if the `COMPATIBLE` initialization parameter is 11.2 or higher and you do not specify `BASICFILE` or `SECUREFILE`, then binary XML data is stored in a SecureFiles LOB whenever

possible. If SecureFiles LOB storage is not possible then the binary XML data is stored in a BasicFiles LOB. This can occur if either of the following is true:

- The tablespace for the `XMLType` table does not use automatic segment space management.
- A setting in file `init.ora` prevents SecureFiles LOB storage. For example, see parameter `DB_SECUREFILE` in *Oracle Database Reference*.
- Specify `CLOB` if you want the database to store the `XMLType` data in a `CLOB` column. Storing data in a `CLOB` column preserves the original content and enhances retrieval time.

If you specify LOB storage, then you can specify either LOB parameters or the `XMLSchema_spec` clause, but not both. Specify the `XMLSchema_spec` clause if you want to restrict the table or column to particular schema-based XML instances.

If you do not specify `BASICFILE` or `SECUREFILE` with this clause, then the `CLOB` column is stored in a BasicFiles LOB.

#### Note:

Oracle recommends against storing `XMLType` data in a `CLOB` column. `CLOB` storage of `XMLType` is deprecated. Use binary XML storage of `XMLType` instead.

- Specify `OBJECT RELATIONAL` if you want the database to store the `XMLType` data in object-relational columns. Storing data objects relationally lets you define indexes on the relational columns and enhances query performance.

If you specify object-relational storage, then you must also specify the `XMLSchema_spec` clause.

Use the `ALL VARRAYS AS` clause if you want the database to store all varrays in an `XMLType` column.

In earlier releases, `XMLType` data is stored in a `CLOB` column in a BasicFiles LOB by default. Beginning with Oracle Database 11g Release 2 (11.2.0.2), if the `COMPATIBLE` initialization parameter is 11.2 or higher and you do not specify the `XMLType_storage` clause, then `XMLType` data is stored in a binary XML column in a SecureFiles LOB. If SecureFiles LOB storage is not possible, then it is stored in a binary XML column in a BasicFiles LOB.

#### See Also:

*Oracle Database SecureFiles and Large Objects Developer's Guide* for more information on SecureFiles LOBs

#### `XMLSchema_spec`

Refer to the [XMLSchema\\_spec](#) for the full semantics of this clause.

 See Also:

- [LOB\\_storage\\_clause](#) for information on the `LOB_segnname` and `LOB_parameters` clauses
- "[XMLType Column Examples](#)" for examples of `XMLType` columns in object-relational tables and "[Using XML in SQL Statements](#)" for an example of creating an XMLSchema
- *Oracle XML DB Developer's Guide* for more information on `XMLType` columns and tables and on creating XMLSchemas
- *Oracle Database PL/SQL Packages and Types Reference* for information on the `DBMS_XMLSHEMA` package

***XMLType\_virtual\_columns***

This clause is valid only for `XMLType` tables with binary XML storage, which you designate in the `XMLType_storage` clause. Specify the `VIRTUAL COLUMNS` clause to define virtual columns, which can be used as in a function-based index or in the definition of a constraint. You cannot define a constraint on such a virtual column during creation of the table, but you can use a subsequent `ALTER TABLE` statement to add a constraint to the column.

 See Also:

*Oracle XML DB Developer's Guide* for examples of how to use this clause in an XML environment

***json\_storage\_clause***

With support for `JSON` data type you can define a column of `JSON` data type using the `JSON_storage_clause`.

**Creating a Table with a JSON Type Column: Example**

This example creates table `j_purchaseorder` with `JSON` data type column `po_document`. Oracle recommends that you store JSON data as `JSON` type.

```
CREATE TABLE j_purchaseorder
  (id VARCHAR2 (32) NOT NULL PRIMARY KEY,
   date_loaded TIMESTAMP (6) WITH TIME ZONE,
   po_document JSON );
```

 See Also:

[Creating a Table with a JSON Column](#)

### *read\_only\_clause*

This clause lets you specify whether to create a table, partition, or subpartition in read-only or read/write mode.

- Use `READ ONLY` to specify read-only mode. When an object is in read-only mode, you cannot issue any DML statements that affect the object or any `SELECT ... FOR UPDATE ...` statements on the object. You can issue DDL statements as long as they do not modify any table data. See *Oracle Database Administrator's Guide* for the complete list of operations that are allowed and disallowed on read-only objects.
- Use `READ WRITE` to specify read/write mode. This is the default.

When you specify this clause for a partitioned table, you specify the default read-only or read/write mode for the table. This mode is assigned to all partitions in the table at creation time, as well as any partitions that are subsequently added to the table, unless you override this behavior by specifying the mode at the partition level.

When you specify this clause for a composite-partitioned table, you specify the default read-only or read/write mode for all partitions in the table. You can override this behavior by specifying this clause for a particular partition. The default mode of a partition is assigned to all subpartitions in the partition at creation time, as well as any subpartitions that are subsequently added to the partition, unless you override this behavior by specifying the mode at the subpartition level.

### *indexing\_clause*

The `indexing_clause` is valid only for partitioned tables. Use this clause to set the **indexing property** for a table, table partition, or table subpartition.

- Specify `INDEXING ON` to set the indexing property to `ON`. This is the default.
- Specify `INDEXING OFF` to set the indexing property to `OFF`.

The indexing property determines whether table partitions and subpartitions are included in partial indexes on the table.

- For simple partitioned tables, partitions with an indexing property of `ON` are included in partial indexes on the table. Partitions with an indexing property of `OFF` are excluded.
- For composite-partitioned tables, subpartitions with an indexing property of `ON` are included in partial indexes on the table. Subpartitions with an indexing property of `OFF` are excluded.

You can specify the `indexing_clause` at the table, partition, or subpartition level. When you specify the `indexing_clause` at the table level, in the `table_properties` clause, you set the default indexing property for the table. Interval partitions, which are automatically created by the database, always inherit the default indexing property for the table. Other types of partitions and subpartitions inherit the default indexing property as follows:

- For simple partitioned tables, partitions inherit the default indexing property for the table. You can override this behavior by specifying the `indexing_clause` for an individual partition:
  - For a range partition, in the `table_partition_description` of the `range_partitions` clause
  - For a hash partition, in the `individual_hash_partitions` clause of the `hash_partitions` clause

- For a list partition, in the `table_partition_description` of the `list_partitions` clause
- For a reference partition, in the `table_partition_description` of the `reference_partition_desc` clause of the `reference_partitioning` clause
- For a system partition, in the `table_partition_description` of the `reference_partition_desc` clause of the `system_partitioning` clause
- For composite-partitioned tables, subpartitions inherit the default indexing property for the table. You can override this behavior by specifying the `indexing_clause` for an individual partition or subpartition.

If you specify the `indexing_clause` for a partition, then its subpartitions inherit the indexing property of the partition:

- For composite range partitions, in the `table_partition_description` of the `composite_range_partitions` clause
- For composite list partitions, in the `table_partition_description` of the `composite_list_partitions` clause
- For composite hash partitions, in the `individual_hash_partitions` clause of the `composite_hash_partitions` clause

You can set the indexing property of a subpartition by specifying the `indexing_clause` for the subpartition:

- For range subpartitions, in the `range_subpartition_desc` clause of the `composite_range_partitions` clause
- For list subpartitions, in the `list_subpartition_desc` clause of the `composite_list_partitions` clause
- For hash subpartitions, in the `individual_hash_subparts` clause of the `composite_hash_partitions` clause

#### See Also:

*Oracle Database Reference* for information on viewing the indexing property of a table, table partition, or table subpartition.

- To view the default indexing property of a table, query the `DEF_INDEXING` column of the `*_PART_TABLES` views.
- To view the indexing property of a table partition, query the `INDEXING` column of the `*_TAB_PARTITIONS` views.
- To view the indexing property of a table subpartition, query the `INDEXING` column of the `*_TAB_SUBPARTITIONS` views.

#### Restrictions on the `indexing_clause`

The `indexing_clause` is subject to the following restrictions:

- You cannot specify the `indexing_clause` for nonpartitioned tables.
- You cannot specify the `indexing_clause` for index-organized tables.

 See Also:

The [partial\\_index\\_clause](#) of CREATE INDEX for more information on partial indexes

### ***table\_partitioning\_clauses***

Use the *table\_partitioning\_clauses* to create a partitioned table.

#### **Notes on Partitioning in General**

The following notes pertain to all types of partitioning:

- You can specify up to a total of 1024K-1 partitions and subpartitions.
- You can create a partitioned table with just one partition. A table with one partition is different from a nonpartitioned table. For example, you cannot add a partition to a nonpartitioned table.
- You can specify a name for every table and LOB partition and for every table and LOB subpartition, but you need not do so. If you specify a name, then it must conform to the rules for naming schema objects and their parts as described in [Database Object Naming Rules](#). If you omit the name, then the database generates names as follows:
  - If you omit a partition name, then the database generates a name of the form `SYS_Pn`. System-generated names for LOB data and LOB index partitions take the form `SYS_LOB_Pn` and `SYS_IL_Pn`, respectively.
  - If you specify a subpartition name in *subpartition\_template*, then for each subpartition created with that template, the database generates a name by concatenating the partition name with the template subpartition name. For LOB subpartitions, the generated LOB subpartition name is a concatenation of the partition name and the template LOB segment name. If the `COMPATIBLE` initialization parameter is set to 12.2 or higher, then the maximum length of the concatenation is 128 bytes; otherwise, the maximum length is 30 bytes. If the concatenation exceeds the maximum length, then the database returns an error and the statement fails.
  - If you omit a subpartition name when specifying an individual subpartition, and you have not specified *subpartition\_template*, then the database generates a name of the form `SYS_SUBPn`. The corresponding system-generated names for LOB data and index subpartitions are `SYS_LOB_SUBPn` and `SYS_IL_SUBPn`, respectively.
- Tablespace storage can be specified at various levels in the CREATE TABLE statement for both table segments and LOB segments. The number of tablespaces does not have to equal the number of partitions or subpartitions. If the number of partitions or subpartitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

The database evaluates tablespace storage in the following order of descending priority:

- Tablespace storage specified at the individual table subpartition or LOB subpartition level has the highest priority, followed by storage specified for the partition or LOB in the *subpartition\_template*.
- Tablespace storage specified at the individual table partition or LOB partition level. Storage parameters specified here take precedence over the *subpartition\_template*.
- Tablespace storage specified for the table

- Default tablespace storage specified for the user
- By default, nested tables are equipartitioned with the partitioned base table.

### Restrictions on Partitioning in General

All partitioning is subject to the following restrictions:

- You cannot partition a table that is part of a cluster.
- You cannot partition a nested table or varray that is defined as an index-organized table.
- You cannot partition a table containing any LONG or LONG RAW columns.

### Restrictions on Hybrid Partitioned Tables

- Restrictions that apply to external tables also apply to hybrid partitioned tables unless explicitly noted. Only DML operations are supported on internal partitions of a hybrid partitioned table (external partitions are treated as read-only partitions).
- Only single level LIST, RANGE, interval and autolist partitioning are supported.
- The following DDLs are supported: ADD PARTITION, ADD SUBPARTITION, DROP PARTITION, DROP SUBPARTITION, EXCHANGE PARTITION, EXCHANGE SUBPARTITION on internal and external partitions and subpartitions. Partitions and subpartitions can also be renamed.
- The DDLs MOVE, SPLIT and MERGE are supported on internal partition and subpartitions only.
- Existing DMLs are supported on internal partitions only. External partitions are treated as read-only. All triggers are supported.
- Table level non-enforced constraints in mandatory RELY DISABLE mode are supported. The only supported enforced constraint is NOT NULL constraint.
- Unique indexes and global unique indexes are not supported. Only non-unique partial indexes are supported on internal partitions. External partitions are not indexable.
- Only single level list partitioning is supported for HIVE.
- Attribute clustering (CLUSTERING clause) is not allowed.
- In-memory defined on the table level only has an effect on internal partitions of the hybrid partitioned table.
- No column default value is allowed.
- Invisible columns are not allowed.
- The CELLMEMORY clause is not allowed.
- SPLIT, MERGE, and MOVE maintenance operations are not allowed on external partitions.

The storage of partitioned database entities in tablespaces of different block sizes is subject to several restrictions. Refer to *Oracle Database VLDB and Partitioning Guide* for a discussion of these restrictions.

 See Also:

["Partitioning Examples"](#)

### *range\_partitions*

Use the *range\_partitions* clause to partition the table on ranges of values from the column list. For an index-organized table, the column list must be a subset of the primary key columns of the table.

#### Restrictions on Range Partitioning

Range partitioning is subject to the restrictions listed in "[Restrictions on Partitioning in General](#)". The following additional restrictions apply:

- You cannot specify more than 16 partitioning key columns.
- Partitioning key columns must be of type CHAR, NCHAR, VARCHAR2, NVARCHAR2, VARCHAR, NUMBER, FLOAT, DATE, TIMESTAMP, TIMESTAMP WITH LOCAL TIMEZONE, or RAW.
- Each range partitioning key column with a character data type that belongs to an XMLType table or a table with an XMLType column, or that is used as a sharding key column must have one of the following declared collations: BINARY, USING\_NLS\_COMP, USING\_NLS\_SORT, or USING\_NLS\_SORT\_CS. For all these collations, partition bounds are checked using the collation BINARY.
- You cannot specify NULL in the VALUES clause.

### *column*

Specify an ordered list of columns used to determine into which partition a row belongs. These columns are the **partitioning key**. You can specify virtual columns and INVISIBLE columns as partitioning key columns.

#### INTERVAL Clause

Use this clause to establish **interval partitioning** for the table. Interval partitions are partitions based on a numeric range or datetime interval. They extend range partitioning by instructing the database to create partitions of the specified range or interval automatically when data inserted into the table exceeds all of the range partitions. For each automatically created partition, the database generates a name of the form `SYS_Pn`. The database guarantees that automatically generated partition names are unique and do not violate namespace rules.

- For *expr*, specify a valid number or interval expression.
- The optional STORE IN clause lets you specify one or more tablespaces into which the database will store interval partition data.
- You must also specify at least one range partition using the PARTITION clause of *range\_partitions*. The range partition key value determines the high value of the range partitions, which is called the **transition point**, and the database creates interval partitions for data beyond that transition point.

#### Restrictions on Interval Partitioning

The INTERVAL clause is subject to the restrictions listed in "[Restrictions on Partitioning in General](#)" and "[Restrictions on Range Partitioning](#)". The following additional restrictions apply:

- You can specify only one partitioning key column, and it must be of type NUMBER, DATE, FLOAT, or TIMESTAMP.
- This clause is not supported for index-organized tables.
- This clause is not supported for tables containing varray columns.
- You cannot create an interval-partitioned table with equipartitioned nested tables. If you create an interval-partitioned table using nested tables or XML object-relational data types, then the nested tables will be created as nonpartitioned tables.
- This clause is supported for tables containing XMLType columns only if the XML data is stored as binary XML.
- Interval partitioning is not supported at the subpartition level.
- Serializable transactions do not work with interval partitioning. Trying to insert data into a partition of an interval partitioned table that does not yet have a segment causes an error.
- In the VALUES clause:
  - You cannot specify MAXVALUE (an infinite upper bound), because doing so would defeat the purpose of the automatic addition of partitions as needed.
  - You cannot specify NULL values for the partitioning key column.

#### See Also:

*Oracle Database VLDB and Partitioning Guide* for more information on interval partitioning

#### PARTITION *partition*

If you specify a partition name, then the name *partition* must conform to the rules for naming schema objects and their part as described in "Database Object Naming Rules". If you omit *partition*, then the database generates a name as described in "Notes on Partitioning in General".

#### *range\_values\_clause*

Specify the noninclusive upper bound for the current partition. The value list is an ordered list of literal values corresponding to the column list in the *range\_partitions* clause. You can substitute the keyword MAXVALUE for any literal in the value list.

MAXVALUE specifies a maximum value that will always sort higher than any other value, including null.

Specifying a value other than MAXVALUE for the highest partition bound imposes an implicit integrity constraint on the table.

 **Note:**

If *table* is partitioned on a `DATE` column, and if the date format does not specify the first two digits of the year, then you must use the `TO_DATE` function with the `YYYY` 4-character format mask for the year. The `RRRR` format mask is not supported in this clause. The date format is determined implicitly by `NLS_TERRITORY` or explicitly by `NLS_DATE_FORMAT`. Refer to *Oracle Database Globalization Support Guide* for more information on these initialization parameters.

 **See Also:**

[Oracle Database Concepts](#) for more information about partition bounds and "[Range Partitioning Example](#)"

***table\_partition\_description***

Use the *table\_partition\_description* to define the physical and storage characteristics of the table.

The clauses `deferred_segment_creation`, `segment_attributes_clause`, `table_compression`, `inmemory_clause`, and `ilm_clause` have the same function as described for the [physical\\_properties](#) of the table as a whole.

Use the `indexing_clause` to set the indexing property for a range, list, system, or reference table partition. Refer to the [indexing\\_clause](#) for more information.

The `prefix_compression` clause and `OVERFLOW` clause, have the same function as described for the [index\\_org\\_table\\_clause](#).

***LOB\_storage\_clause***

The `LOB_storage_clause` lets you specify LOB storage characteristics for one or more LOB items in this partition or in any range or list subpartitions of this partition. If you do not specify the `LOB_storage_clause` for a LOB item, then the database generates a name for each LOB data partition as described in "[Notes on Partitioning in General](#)".

***varray\_col\_properties***

The `varray_col_properties` let you specify storage characteristics for one or more varray items in this partition or in any range or list subpartitions of this partition.

***nested\_table\_col\_properties***

The `nested_table_col_properties` let you specify storage characteristics for one or more nested table storage table items in this partition or in any range or list subpartitions of this partition. Storage characteristics specified in this clause override any storage attributes specified at the table level.

***partitioning\_storage\_clause***

Use the `partitioning_storage_clause` to specify storage characteristics for hash partitions and for range, hash, and list subpartitions.

## Restrictions on *partitioning\_storage\_clause*

This clause is subject to the following restrictions:

- The `TABLESPACE SET` clause is valid only when creating a sharded table by specifying the `SHARDED` keyword of `CREATE TABLE`. Use this clause to specify the tablespace set in which table partition data is to be stored.
- The `OVERFLOW` clause is relevant only for index-organized partitioned tables and is valid only within the `individual_hash_partitions` clause. It is not valid for range or hash partitions or for subpartitions of any type.
- You cannot specify the `advanced_index_compression` clause of the `index_compression` clause.
- You can specify the `prefix_compression` clause of the `indexing_clause` only for partitions of index-organized tables and you can specify `COMPRESS` or `NOCOMPRESS`, but you cannot specify the prefix length with `integer`.

## *list\_partitions*

Use the `list_partitions` clause to partition the table on a list of literal values for each column in the `column` list. List partitioning is useful for controlling how individual rows map to specific partitions.

### Restrictions on List Partitioning

List partitioning is subject to the restrictions listed in "[Restrictions on Partitioning in General](#)". The following additional restrictions apply:

- You cannot specify more than 16 partitioning key columns.
- You cannot specify more than one partitioning key column when partitioning an index-organized table.
- The partitioning key columns must be of type `CHAR`, `NCHAR`, `VARCHAR2`, `NVARCHAR2`, `VARCHAR`, `NUMBER`, `FLOAT`, `DATE`, `TIMESTAMP`, `TIMESTAMP WITH LOCAL TIMEZONE`, or `RAW`.
- Each list partitioning key column with a character data type that belongs to an `XMLType` table or a table with an `XMLType` column, or that is used as a sharding key column must have one of the `BINARY` following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`. For all these collations, partitions are matched using the collation `BINARY`.

## AUTOMATIC

Specify `AUTOMATIC` to create an automatic list-partitioned table. This type of table enables the database to create additional partitions on demand.

When you create an automatic list-partitioned table, you specify partitions and partitioning key values just as you would when creating a regular list-partitioned table. However, you do not specify a `DEFAULT` partition. As data is loaded into the table, the database automatically creates a new partition when the loaded partitioning key values do not correspond to any of the existing partitions. If list partitioning is defined with a single partitioning key value, then the database creates a new partition for each new partitioning key value. If list partitioning is defined with multiple partitioning key columns, then the database creates a new partition for each new and unique set of partitioning key values. For each automatically created partition, the database generates a name of the form `SYS_Pn`. The database guarantees that automatically generated partition names are unique and do not violate namespace rules.

You can specify the `AUTOMATIC` keyword for list-partitioned tables, and list-range, list-list, list-hash, and list-interval composite-partitioned tables. For composite-partitioned tables, each automatically created list partition will have one subpartition, unless a subpartition template is defined for the table.

If a local partitioned index is defined on an automatic list-partitioned table, then local index partitions will be created when the corresponding table partitions are created.

### Restrictions on Automatic List Partitioning

Automatic list partitioning is subject to the restrictions listed in "[Restrictions on List Partitioning](#)". The following additional restrictions apply:

- An automatic list-partitioned table must have at least one partition when created. Because new partitions are automatically created for new, and unknown, partitioning key values, an automatic list-partitioned table cannot have a `DEFAULT` partition.
- Automatic list partitioning is not supported for index-organized tables or external tables.
- Automatic list partitioning is not supported for tables containing varray columns.
- You cannot create a local domain index on an automatic list-partitioned table. You can create a global domain index on an automatic list-partitioned table.
- An automatic list-partitioned table cannot be a child table or a parent table for reference partitioning.
- Automatic list partitioning is not supported at the subpartition level.

### STORE IN

The optional `STORE IN` clause lets you specify one or more tablespaces into which the database will store data for the automatically created list partitions.

#### Note:

You can change an automatic list-partitioned table to a regular list-partitioned table, and vice versa. You can also change the tablespaces into which the database will store data for automatically created list partitions. See the clause [`alter\_automatic\_partitioning`](#) of `ALTER TABLE` for more information.

### *list\_values\_clause*

The `list_values_clause` of each partition must have at least one value. If the table is partitioned on one key column, then use the upper branch of the `list_values` syntax to specify a list of values for that column. In this case, no value, including `NULL`, can appear in more than one partition. If the table is partitioned on multiple key columns, then use the lower branch of the `list_values` syntax to specify a list of value lists. Each value list is enclosed in parentheses and represents a list of values for the key columns. In this case, individual key column values can appear in more than one partition; however, no complete value list can appear in more than one partition. List partitions are not ordered.

If you specify the literal `NULL` for a partition value in the `VALUES` clause, then to access data in that partition in subsequent queries, you must use an `IS NULL` condition in the `WHERE` clause, rather than a comparison condition.

The `DEFAULT` keyword creates a partition into which the database will insert any row that does not map to another partition. Therefore, you can specify `DEFAULT` for only one partition, and you cannot specify any other values for that partition. Further, the default partition must be the last partition you define. The use of `DEFAULT` is similar to the use of `MAXVALUE` for range partitions.

The string comprising the list of values for each partition can be up to 4K bytes. The total number of values for all partitions cannot exceed 64K-1.

The partitioning key column for a list partition can be an extended data type column, which has a maximum size of 32767 bytes. In this case, the list of values that you want to specify for a partition may exceed the 4K byte limit. You can work around this limitation by using one of the following methods:

- Use the `DEFAULT` partition for values that exceed the 4K byte limit.
- Use a hash function, such as `STANDARD_HASH`, in the partition key column to create unique identifiers of lengths less than 4K bytes. See [STANDARD\\_HASH](#) for more information.

#### Restriction on the *list\_values\_clause*

You cannot specify a `DEFAULT` partition for an automatic list-partitioned table.

#### See Also:

"[Extended Data Types](#)" for more information on extended data types

#### *table\_partition\_description*

The subclauses of the `table_partition_description` have the same behavior as described for range partitions in [table\\_partition\\_description](#).

#### *hash\_partitions*

Use the `hash_partitions` clause to specify that the table is to be partitioned using the hash method. Oracle Database assigns rows to partitions using a hash function on values found in columns designated as the partitioning key. You can specify individual hash partitions, or you can specify how many hash partitions the database should create.

#### Restrictions on Hash Partitioning

Hash partitioning is subject to the restrictions listed in "[Restrictions on Partitioning in General](#)". The following additional restrictions apply:

- You cannot specify more than 16 partitioning key columns.
- Partitioning key columns must be of type CHAR, NCHAR, VARCHAR2, NVARCHAR2, VARCHAR, NUMBER, FLOAT, DATE, TIMESTAMP, TIMESTAMP WITH LOCAL TIMEZONE, or RAW.
- Each hash partitioning key column with a character data type that belongs to an XMLType table or a table with an XMLType column, or that is used as a sharding key column must have one of the following declared collations: BINARY, USING\_NLS\_COMP, USING\_NLS\_SORT, or USING\_NLS\_SORT\_CS.

#### *column*

Specify an ordered list of columns used to determine into which partition a row belongs (the partitioning key).

#### *individual\_hash\_partitions*

Use this clause to specify individual partitions by name.

Use the *indexing\_clause* to set the indexing property for a hash partition. Refer to the *indexing\_clause* for more information.

#### **Restriction on Specifying Individual Hash Partitions**

The only clauses you can specify in the *partitioning\_storage\_clause* are the TABLESPACE clause and table compression.

##### **Note:**

If your enterprise has or will have databases using different character sets, then use caution when partitioning on character columns. The sort sequence of characters is not identical in all character sets. Refer to *Oracle Database Globalization Support Guide* for more information on character set support.

#### *hash\_partitions\_by\_quantity*

An alternative to defining individual partitions is to specify the number of hash partitions. In this case, the database assigns partition names of the form `SYS_Pn`. The STORE IN clause lets you specify one or more tablespaces where the hash partition data is to be stored. The number of tablespaces need not equal the number of partitions. If the number of partitions is greater than the number of tablespaces, then the database cycles through the names of the tablespaces.

For both methods of hash partitioning, for optimal load balancing you should specify a number of partitions that is a power of 2. When you specify individual hash partitions, you can specify both TABLESPACE and table compression in the *partitioning\_storage\_clause*. When you specify hash partitions by quantity, you can specify only TABLESPACE. Hash partitions inherit all other attributes from table-level defaults.

The *table\_compression* clause has the same function as described for the *table\_properties* of the table as a whole.

The *prefix\_compression* clause and the OVERFLOW clause have the same function as described for the *index\_org\_table\_clause*.

Tablespace storage specified at the table level is overridden by tablespace storage specified at the partition level, which in turn is overridden by tablespace storage specified at the subpartition level.

In the *individual\_hash\_partitions* clause, the TABLESPACE clause of the *partitioning\_storage\_clause* determines tablespace storage only for the individual partition being created. In the *hash\_partitions\_by\_quantity* clause, the STORE IN clause determines placement of partitions as the table is being created and the default storage location for subsequently added partitions.

#### **Restriction on Specifying Hash Partitions by Quantity**

You cannot specify the `advanced_index_compression` clause of the `index_compression` clause.

 **See Also:**

*Oracle Database VLDB and Partitioning Guide* for more information on hash partitioning

### ***composite\_range\_partitions***

Use the `composite_range_partitions` clause to first partition `table` by range, and then partition the partitions further into range, hash, or list subpartitions.

The `INTERVAL` clause has the same semantics for composite range partitioning that it has for range partitioning. Refer to "INTERVAL Clause" for more information.

Specify `subpartition_by_range`, `subpartition_by_hash` or `subpartition_by_list` to indicate the type of subpartitioning you want for each composite range partition. Within these clauses you can specify a subpartition template, which establishes default subpartition characteristics for subpartitions created as part of this statement or subsequently created subpartitions.

After establishing the type of subpartitioning you want for the table, and optionally a subpartition template, you must define at least one range partition.

- You must specify the `range_values_clause`, which has the same requirements as for noncomposite range partitions.
- Use the `table_partition_description` to define the physical and storage characteristics of the each partition.
- In the `range_partition_desc`, use `range_subpartition_desc`, `list_subpartition_desc`, `individual_hash_subparts`, or `hash_subparts_by_quantity` to specify characteristics for the individual subpartitions of the partition. The values you specify in these clauses supersede for these subpartitions any values you have specified in the `subpartition_template`.
- The only characteristics you can specify for a hash or list subpartition or any LOB subpartition are `TABLESPACE` and `table_compression`.

### **Restrictions on Composite Range Partitioning**

Regardless of the type of subpartitioning, composite range partitioning is subject to the following restrictions:

- The only physical attributes you can specify at the subpartition level are `TABLESPACE` and `table compression`.
- You cannot specify composite partitioning for an index-organized table. Therefore, the `OVERFLOW` clause of the `table_partition_description` is not valid for composite-partitioned tables.
- You cannot specify composite partitioning for tables containing `XMLType` columns.
- Each range, list, or hash subpartitioning key column with a character data type that belongs to an `XMLType` table or a table with an `XMLType` column must have one of

the following declared collations: BINARY, USING\_NLS\_COMP, USING\_NLS\_SORT, or USING\_NLS\_SORT\_CS.

#### See Also:

"[Composite-Partitioned Table Examples](#)" for examples of composite range partitioning and *Oracle Database VLDB and Partitioning Guide* for examples of composite list partitioning

### ***composite\_list\_partitions***

Use the *composite\_list\_partitions* clause to first partition *table* by list, and then partition the partitions further into range, hash, or list subpartitions.

Specify *subpartition\_by\_range*, *subpartition\_by\_hash* or *subpartition\_by\_list* to indicate the type of subpartitioning you want for each composite list partition. Within these clauses you can specify a subpartition template, which establishes default subpartition characteristics for subpartitions created as part of this statement and for subsequently created subpartitions.

After establishing the type of subpartitioning you want for each composite partition, and optionally defining a subpartition template, you must define at least one list partition.

- In the *list\_partition\_desc*, you must specify the *list\_values\_clause*, which has the same requirements as for noncomposite list partitions.
- Use the *table\_partition\_description* to define the physical and storage characteristics of the each partition.
- In the *list\_partition\_desc*, use *range\_subpartition\_desc*, *list\_subpartition\_desc*, *individual\_hash\_subparts*, or *hash\_subparts\_by\_quantity* to specify characteristics for the individual subpartitions of the partition. The values you specify in these clauses supersede the for these subpartitions any values you have specified in the *subpartition\_template*.

Specify AUTOMATIC to create an automatic list-range, list-list, list-hash, or list-interval composite-partitioned table. This type of table enables the database to create additional partitions on demand. The optional STORE IN clause lets you specify one or more tablespaces into which the database will store data for the automatically created partitions. The AUTOMATIC and STORE IN clauses have the same semantics here as they have for noncomposite list partitions. Refer to [AUTOMATIC](#) and [STORE IN](#) in the documentation on *list\_partitions* for the full semantics of these clauses. Automatic composite-partitioned tables are subject to the restrictions listed in [Restrictions on Composite List Partitioning](#) and [Restrictions on Automatic List Partitioning](#).

#### **Restrictions on Composite List Partitioning**

Composite list partitioning is subject to the same restrictions as described in "[Restrictions on Composite Range Partitioning](#)".

### ***composite\_hash\_partitions***

Use the *composite\_hash\_partitions* clause to first partition *table* using the hash method, and then partition the partitions further into range, hash, or list subpartitions.

Specify *subpartition\_by\_range*, *subpartition\_by\_hash* or *subpartition\_by\_list* to indicate the type of subpartitioning you want for each composite range partition. Within these clauses you

can specify a subpartition template, which establishes default subpartition characteristics for subpartitions created as part of this statement or subsequently created subpartitions.

After establishing the type of subpartitioning you want for the table, you must specify *individual\_hash\_partitions* or *hash\_partitions\_by\_quantity*.

### Restrictions on Composite Hash Partitioning

Composite hash partitioning is subject to the same restrictions as described in "Restrictions on Composite Range Partitioning".

#### *subpartition\_template*

The *subpartition\_template* is an optional element of range, list, and hash subpartitioning. The template lets you define default subpartitions for each table partition. Oracle Database will create these default subpartition characteristics in any partition for which you do not explicitly define subpartitions. This clause is useful for creating symmetric partitions. You can override this clause by explicitly defining subpartitions at the partition level, in the *range\_subpartition\_desc*, *list\_subpartition\_desc*, *individual\_hash\_subparts*, or *hash\_subparts\_by\_quantity* clause.

When defining subpartitions with a template, you can explicitly define range, list, or hash subpartitions, or you can define a quantity of hash subpartitions.

- To explicitly define subpartitions, use *range\_subpartition\_desc*, *list\_subpartition\_desc*, or *individual\_hash\_subparts*. You must specify a name for each subpartition. If you specify the *LOB\_partitioning\_clause* of the *partitioning\_storage\_clause*, then you must specify *LOB\_segname*.
- To define a quantity of hash subpartitions, specify a positive integer for *hash\_subpartition\_quantity*. The database creates that number of subpartitions in each partition and assigns subpartition names of the form *SYS\_SUBPn*.

#### Note:

When you specify tablespace storage for the subpartition template, it does not override any tablespace storage you have specified explicitly for the partitions of *table*. To specify tablespace storage for subpartitions, do one of these things:

- Omit tablespace storage at the partition level and specify tablespace storage in the subpartition template.
- Define individual subpartitions with specific tablespace storage.

### Restrictions on Subpartition Templates

Subpartition templates are subject to the following restrictions:

- If you specify *TABLESPACE* for one LOB subpartition, then you must specify *TABLESPACE* for all of the LOB subpartitions of that LOB column. You can specify the same tablespace for more than one LOB subpartition.

- If you specify separate LOB storage for list subpartitions using the *partitioning\_storage\_clause*, either in the *subpartition\_template* or when defining individual subpartitions, then you must specify *LOB\_segnane* for both LOB and varray columns.

#### ***subpartition\_by\_range***

Use the *subpartition\_by\_range* clause to indicate that the database should subpartition by range each partition in *table*. The subpartitioning column list is unrelated to the partitioning key but is subject to the same restrictions (see [column](#)).

You can use the *subpartition\_template* to specify default subpartition characteristic values. See [subpartition\\_template](#). The database uses these values for any subpartition in this partition for which you do not explicitly specify the characteristic.

You can also define range subpartitions individually for each partition using the *range\_subpartition\_desc* of *range\_partition\_desc* or *list\_partition\_desc*. If you omit both *subpartition\_template* and the *range\_subpartition\_desc*, then the database creates a single MAXVALUE subpartition.

#### ***subpartition\_by\_list***

Use the *subpartition\_by\_list* clause to indicate that the database should subpartition each partition in the table on lists of literal values from the *column* list. You can specify a maximum of 16 list subpartitioning key columns.

You can use the *subpartition\_template* to specify default subpartition characteristic values. See [subpartition\\_template](#). The database uses these values for any subpartition in this partition for which you do not explicitly specify the characteristic.

You can also define list subpartitions individually for each partition using the *list\_subpartition\_desc* of *range\_partition\_desc* or *list\_partition\_desc*. If you omit both *subpartition\_template* and the *list\_subpartition\_desc*, then the database creates a single DEFAULT subpartition.

#### **Restrictions on List Subpartitioning**

List subpartitioning is subject to the same restrictions as described in [Restrictions on Composite Range Partitioning](#).

#### ***subpartition\_by\_hash***

Use the *subpartition\_by\_hash* clause to indicate that the database should subpartition by hash each partition in *table*. The subpartitioning column list is unrelated to the partitioning key but is subject to the same restrictions (see [column](#)).

You can define the subpartitions using the *subpartition\_template* or the SUBPARTITIONS *integer* clause. See [subpartition\\_template](#). In either case, for optimal load balancing you should specify a number of partitions that is a power of 2.

If you specify SUBPARTITIONS *integer*, then you determine the default number of subpartitions in each partition of *table*, and optionally one or more tablespaces in which they are to be stored. The default value is 1. If you omit both this clause and *subpartition\_template*, then the database will create each partition with one hash subpartition.

## Notes on Composite Partitions

The following notes apply to composite partitions:

- For all subpartitions, you can use the `range_subpartition_desc`, `list_subpartition_desc`, `individual_hash_subparts`, or `hash_subparts_by_quantity` to specify individual subpartitions by name, and optionally some other characteristics.
- Alternatively, for hash and list subpartitions:
  - You can specify the number of subpartitions and optionally one or more tablespaces where they are to be stored. In this case, Oracle Database assigns subpartition names of the form `SYS_SUBPn`.
  - If you omit the subpartition description and if you have created a subpartition template, then the database uses the template to create subpartitions. If you have not created a subpartition template, then the database creates one hash subpartition or one `DEFAULT` list subpartition.
- For all types of subpartitions, if you omit the subpartitions description entirely, then the database assigns subpartition names as follows:
  - If you have specified a subpartition template *and* you have specified partition names, then the database generates subpartition names of the form `partition_name underscore (_) subpartition_name` (for example, `P1_SUB1`).
  - If you have not specified a subpartition template *or* if you have specified a subpartition template but did not specify partition names, then the database generates subpartition names of the form `SYS_SUBPn`.

### ***reference\_partitioning***

Use this clause to partition the table by reference. Partitioning by reference is a method of equipartitioning the table being created (the **child table**) by a referential constraint to an existing partitioned table (the **parent table**). When you partition a table by reference, partition maintenance operations subsequently performed on the parent table automatically cascade to the child table. Therefore, you cannot perform partition maintenance operations on a reference-partitioned table directly.

If the parent table is an interval-partitioned table, then partitions in the reference-partitioned child table that correspond to interval partitions in the parent table will be created during inserts into the child table. When an interval partition in a child table is created, the partition name is inherited from the associated parent table partition. If the child table has a table-level default tablespace, then it will be used as the tablespace for the new interval partition. Otherwise, the tablespace will be inherited from the parent table partition. Refer to *Oracle Database VLDB and Partitioning Guide* for more information on referencing an interval-partitioned table.

### ***constraint***

The partitioning referential constraint must meet the following conditions:

- You must specify a referential integrity constraint defined on the table being created, which must refer to a primary key or unique constraint on the parent table. The constraint must be in `ENABLE VALIDATE NOT DEFERRABLE` state, which is the default when you specify a referential integrity constraint during table creation.
- All foreign key columns referenced in the constraint must be `NOT NULL`.

- When you specify the constraint, you cannot specify the ON DELETE SET NULL clause of the `references_clause`.
- The parent table referenced in the constraint must be an existing partitioned table. It can be partitioned by any method.
- The foreign and parent keys cannot contain any virtual columns that reference PL/SQL functions or LOB columns.

#### ***reference\_partition\_desc***

Use this optional clause to specify partition names and to define the physical and storage characteristics of the partition. The subclauses of the `table_partition_description` have the same behavior as described for range partitions in [table\\_partition\\_description](#).

If you specify this clause when creating a reference-partitioned child table whose parent is an interval-partitioned table, then the partition descriptors are used for the child table's non-interval partitions. Partition descriptors cannot be specified for interval partitions.

#### **Restrictions on Reference Partitioning**

Reference partitioning is subject to the restrictions listed in [Restrictions on Partitioning in General](#). The following additional restrictions apply:

- Restrictions for reference partitioning are derived from the partitioning strategy of the parent table.
- Neither the parent table nor the child table can be an automatic list-partitioned table.
- You cannot specify this clause for an index-organized table, an external table, or a domain index storage table.
- The parent table can be partitioned by reference, but `constraint` cannot be self-referential. The table being created cannot be partitioned based on a reference to itself.
- If `ROW MOVEMENT` is enabled for the parent table, it must also be enabled for the child table.

#### **See Also:**

[Oracle Database VLDB and Partitioning Guide](#) for more information on partitioning by reference and "[Reference Partitioning Example](#)"

#### ***system\_partitioning***

Use this clause to create system partitions. System partitioning does not entail any partitioning key columns, nor do system partitions have any range or list bounds or hash algorithms. Rather, they provide a way to equipartition dependent tables such as nested table or domain index storage tables with partitioned base tables.

- If you specify only `PARTITION BY SYSTEM`, then the database creates one partition with a system-generated name of the form `SYS_Pn`.
- If you specify `PARTITION BY SYSTEM PARTITIONS integer`, then the database creates as many partitions as you specify in `integer`, which can range from 1 to 1024K-1.
- The description of the partition takes the same syntax as reference partitions, so they share the `reference_partition_desc`. You can specify additional partition attributes with

the `reference_partition_desc` syntax. However, within the `table_partition_description`, you cannot specify the `OVERFLOW` clause.

### Restrictions on System Partitioning

System partitioning is subject to the following restrictions:

- You cannot system partition an index-organized table or a table that is part of a cluster.
- Composite partitioning is not supported with system partitioning.
- You cannot split a system partition.
- You cannot specify system partitioning in a `CREATE TABLE ... AS SELECT` statement.
- To insert data into a system-partitioned table using an `INSERT INTO ... AS subquery` statement, you must use partition-extended syntax to specify the partition into which the values returned by the subquery will be inserted.

#### See Also:

Refer to *Oracle Database Data Cartridge Developer's Guide* for information on the uses for system partitioning and "[References to Partitioned Tables and Indexes](#)"

### `consistent_hash_partitions`

This clause is valid only for sharded tables. Use this clause to create consistent hash partitions.

Each sharding key column with a character data type must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.

### `directory_based_partitions`

Use this clause to create a sharded table with directory-based sharding.

The restrictions that apply to sharded tables apply to tables sharded by directory.

### Example: Create Sharded Table and Partition by Directory

```
CREATE SHARDED TABLE departments
  (
    department_id NUMBER(6)
   , department_name VARCHAR2(30) CONSTRAINT dept_name_nn NOT NULL
   , manager_id NUMBER(6)
   , location_id NUMBER(4)
   , CONSTRAINT dept_id_pk PRIMARY KEY(department_id)
  )
PARTITION BY DIRECTORY (department_id)
(
  PARTITION p_1 TABLESPACE tbs1,
  PARTITION p_2 TABLESPACE tbs2
);
```

In the example above, when you partition by directory the partition names `p_1` and `p_2` do not have value list after them. This is different from partition by list.

***consistent\_hash\_with\_subpartitions***

This clause is valid only for sharded tables. Use this clause to create consistent hash with subpartitions.

Each sharding key column with a character data type must have one of the following declared collations: BINARY, USING\_NLS\_COMP, USING\_NLS\_SORT, or USING\_NLS\_SORT\_CS.

***range\_partitionset\_clause***

Use this clause to create a range partition set.

In the SUBPARTITION BY clause, within the *subpartition\_template* clause, you cannot specify a tablespace for a subpartition. That is, for range, list, and individual hash subpartitions, you cannot specify the TABLESPACE clause of the *partitioning\_storage\_clause*, and in the *hash\_subpartitions\_by\_quantity* clause, you cannot specify the STORE IN (*tablespace*) clause.

In the PARTITIONS AUTO clause, within the *subpartition\_template* clause of the *range\_partitionset\_desc* clause, you can specify a tablespace for a subpartition.

Each super sharding or sharding key column with a character data type must have one of the following declared collations: BINARY, USING\_NLS\_COMP, USING\_NLS\_SORT, or USING\_NLS\_SORT\_CS.

***list\_partitionset\_clause***

Use this clause to create a list partition set.

In the SUBPARTITION BY clause, within the *subpartition\_template* clause, you cannot specify a tablespace for a subpartition. That is, for range, list, and individual hash subpartitions, you cannot specify the TABLESPACE clause of the *partitioning\_storage\_clause*, and in the *hash\_subpartitions\_by\_quantity* clause, you cannot specify the STORE IN (*tablespace*) clause.

In the PARTITIONS AUTO clause, within the *subpartition\_template* clause of the *list\_partitionset\_desc* clause, you can specify a tablespace for a subpartition.

Each super sharding or sharding key column with a character data type must have one of the following declared collations: BINARY, USING\_NLS\_COMP, USING\_NLS\_SORT, or USING\_NLS\_SORT\_CS.

***attribute\_clustering\_clause***

Use this clause to enable the table for attribute clustering. Attribute clustering lets you cluster data in close physical proximity based on the content of specified columns.

Attribute clustering can be based only on columns in *table* or on joined values from other tables. The latter is called join attribute clustering.

 **See Also:**

*Oracle Database Data Warehousing Guide* for more information on attribute clustering

***clustering\_join***

Use this clause to specify join attribute clustering. Use the `JOIN` clause to specify the joined values from other tables on which to base the attribute clustering. You can specify a maximum of four `JOIN` clauses.

***cluster\_clause***

Use this clause to specify the type of ordering to use for the table: linear ordering or interleaved ordering. If you do not specify the `LINEAR` or `INTERLEAVED` keyword, then the default is `LINEAR`.

**BY LINEAR ORDER**

Use this clause to specify linear ordering. This type of ordering stores data according to the order of the specified columns. If you specify this clause, then you can specify only one clustering column group, which can contain at most 10 columns.

**BY INTERLEAVED ORDER**

Use this clause to specify interleaved ordering. This type of ordering uses a special multidimensional clustering technique, similar to z-ordering, that permits multicolumn clustering. If you specify this clause, then you can specify at most four clustering column groups, with a maximum of 40 columns across all groups.

***clustering\_columns***

Use this clause to specify one or more clustering column groups.

***clustering\_column\_group***

Use this clause to specify one or more columns to be included in the clustering column group.

**Restriction on Attribute Clustering Columns**

Each character column in the clustering column group must have one of the following declared collations: `BINARY` or `USING_NLS_COMP`.

***clustering\_when***

Use these clauses to allow or disallow attribute clustering during direct-path insert operations and data movement operations.

**ON LOAD**

Specify `YES ON LOAD` to allow, or `NO ON LOAD` to disallow, attribute clustering during direct-path inserts (serial or parallel) resulting either from an `INSERT` or a `MERGE` operation.

The default is `YES ON LOAD`.

**ON DATA MOVEMENT**

Specify `YES ON DATA MOVEMENT` to allow, or `NO ON DATA MOVEMENT` to disallow, attribute clustering for data movement that occurs during the following operations:

- Data redefinition using the `DBMS_REDEFINITION` package
- Table partition maintenance operations that are specified by the following clauses of `ALTER TABLE`: `coalesce_table`, `merge_table_partitions`, `move_table_partition`, and `split_table_partition`

The default is YES ON DATA MOVEMENT.

#### ***zonemap\_clause***

Use this clause to create a zone map on the table. The zone map tracks the columns specified in the *clustering\_columns* clause.

- Specify WITH MATERIALIZED ZONEMAP to create a zone map. For *zonemap\_name*, specify the name of the zone map to be created. If you omit *zonemap\_name*, then the name of the zone map is *ZMAP\$\_table*.
- Specify WITHOUT MATERIALIZED ZONEMAP to not create a zone map. This is the default.

If you subsequently drop the table or use the ALTER TABLE statement to DROP CLUSTERING or MODIFY CLUSTERING ... WITHOUT MATERIALIZED ZONEMAP, then the zone map will be dropped.

#### **See Also:**

[CREATE MATERIALIZED ZONEMAP](#) for more information on zone maps

### **Restrictions on Attribute Clustering**

The following restrictions apply to attribute clustering:

- Attribute clustering is not supported for temporary tables or external tables.
- The table being created must be a heap-organized table. However, tables specified in the *clustering\_join* clause can be heap-organized or index-organized tables.
- Clustering columns must be of a scalar data type and cannot be encrypted.
- If you specify BY LINEAR ORDER, then you can specify only one clustering column group, which can contain at most 10 columns.
- If you specify BY INTERLEAVED ORDER, then you can specify at most four clustering column groups, with a maximum of 40 columns across all groups.
- For join attribute clustering:
  - The number of dimension tables cannot exceed four.
  - The join to the table or tables providing the attribute clustering columns must be on a unique key or primary key column to avoid row duplication.
- Attribute clustering will not order rows that are inserted using MERGE statements or multitable insert operations.

### **CACHE | NOCACHE | CACHE READS**

Use these clauses to indicate how Oracle Database should store blocks in the buffer cache. For LOB storage, you can specify CACHE, NOCACHE, or CACHE READS. For other types of storage, you can specify only CACHE or NOCACHE.

If you omit these clauses, then:

- In a CREATE TABLE statement, NOCACHE is the default.
- In an ALTER TABLE statement, the existing value is not changed.

The behavior of `CACHE` and `NOCACHE` described in this section does not apply when Oracle Database chooses to use direct reads or to perform table scans using parallel query.

### **CACHE**

For data that is accessed frequently, this clause indicates that the blocks retrieved for this table are placed at the most recently used end of the least recently used (LRU) list in the buffer cache when a full table scan is performed. This attribute is useful for small lookup tables.

 **See Also:**

*Oracle Database Concepts* for more information on how the database maintains the least recently used (LRU) list

As a parameter in the `LOB_storage_clause`, `CACHE` specifies that the database places LOB data values in the buffer cache for faster access. The database evaluates this parameter in conjunction with the `logging_clause`. If you omit this clause, then the default value for both BasicFiles and SecureFiles LOBs is `NOCACHE LOGGING`.

### **Restriction on CACHE**

You cannot specify `CACHE` for an index-organized table. However, index-organized tables implicitly provide `CACHE` behavior.

### **NOCACHE**

For data that is not accessed frequently, this clause indicates that the blocks retrieved for this table are placed at the least recently used end of the LRU list in the buffer cache when a full table scan is performed. `NOCACHE` is the default for LOB storage.

As a parameter in the `LOB_storage_clause`, `NOCACHE` specifies that the LOB values are not brought into the buffer cache. `NOCACHE` is the default for LOB storage.

### **Restriction on NOCACHE**

You cannot specify `NOCACHE` for an index-organized table.

### **CACHE READS**

`CACHE READS` applies only to LOB storage. It specifies that LOB values are brought into the buffer cache only during read operations but not during write operations.

### ***logging\_clause***

Use this clause to indicate whether the storage of data blocks should be logged or not.

 **See Also:**

*logging\_clause* for a description of the `logging_clause` when specified as part of `LOB_parameters`

### ***result\_cache\_clause***

Use this clause to determine whether the results of statements or query blocks that name this table are considered for storage in the result cache.

You can use mode `DEFAULT` or mode `FORCE` for result caching, with `STANDBY` enabled or disabled.

- `DEFAULT`: Result caching is not determined at the table level. The query is considered for result caching if the `RESULT_CACHE_MODE` initialization parameter is set to `FORCE`, or if that parameter is set to `MANUAL` and the `RESULT_CACHE` hint is specified in the query. This is the default if you omit this clause.
- `FORCE`: If all tables names in the query have this setting, then the query is always considered for caching unless the `NO_RESULT_CACHE` hint is specified for the query. If one or more tables named in the query are set to `DEFAULT`, then the effective table annotation for that query is considered to be `DEFAULT`, with the semantics described above.
- The default value of `STANDBY` is `DISABLE`.
- You must enable `STANDBY` on all the dependent objects of a query to save the result of the query into the result cache.
- A transaction must enable `STANDBY` on an object in order to generate a redo marker at transaction commit time on the primary.

You can query the `RESULT_CACHE` column of the `DBA_`, `ALL_`, and `USER_TABLES` data dictionary views to learn the result cache mode of the table.

The `RESULT_CACHE` and `NO_RESULT_CACHE` SQL hints take precedence over these result cache table annotations and the `RESULT_CACHE_MODE` initialization parameter. The `RESULT_CACHE_MODE` setting of `FORCE` in turn takes precedence over this table annotation clause.

#### **Note:**

The `RESULT_CACHE_MODE` setting of `FORCE` is not recommended, as it can cause significant performance and latching overhead, as database and clients will try to cache all queries.

#### **See Also:**

- *Oracle Call Interface Programmer's Guide* and *Oracle Database Concepts* for general information about result caching
- *Oracle Database Performance Tuning Guide* for information about using this clause
- *Oracle Database Reference* for information about the `RESULT_CACHE_MODE` initialization parameter and the `*_TABLES` data dictionary views
- "["RESULT\\_CACHE Hint"](#)" and "["NO\\_RESULT\\_CACHE Hint"](#)" for information about the hints

### ***parallel\_clause***

The *parallel\_clause* lets you parallelize creation of the table and set the default degree of parallelism for queries and the DML INSERT, UPDATE, DELETE, and MERGE after table creation.

#### **Note:**

The syntax of the *parallel\_clause* supersedes syntax appearing in earlier releases of Oracle. The superseded syntax is still supported for backward compatibility, but may result in slightly different behavior from that documented.

### **NOPARALLEL**

Specify NOPARALLEL for serial execution. This is the default.

### **PARALLEL**

Specify PARALLEL if you want Oracle to select a degree of parallelism equal to the number of CPUs available on all participating instances times the value of the PARALLEL\_THREADS\_PER\_CPU initialization parameter.

### **PARALLEL *integer***

Specification of *integer* indicates the **degree of parallelism**, which is the number of parallel threads used in the parallel operation. Each parallel thread may use one or two parallel execution servers. Normally Oracle calculates the optimum degree of parallelism, so it is not necessary for you to specify *integer*.

#### **See Also:**

[parallel\\_clause](#) for more information on this clause

### **NOROWDEPENDENCIES | ROWDEPENDENCIES**

This clause lets you specify whether *table* will use **row-level dependency tracking**. With this feature, each row in the table has a system change number (SCN) that represents a time greater than or equal to the commit time of the last transaction that modified the row. You cannot change this setting after *table* is created.

### **ROWDEPENDENCIES**

Specify ROWDEPENDENCIES if you want to enable row-level dependency tracking. This setting is useful primarily to allow for parallel propagation in replication environments. It increases the size of each row by 6 bytes.

#### **Restriction on the ROWDEPENDENCIES Clause**

Oracle does not support table compression for tables that use row-level dependency tracking. If you specify both the ROWDEPENDENCIES clause and the *table\_compression* clause, then the *table\_compression* clause is ignored. To remove the

ROWDEPENDENCIES attribute, you must redefine the table using the DBMS\_REDEFINITION package or recreate the table.

### NOROWDEPENDENCIES

Specify NOROWDEPENDENCIES if you do not want *table* to use the row-level dependency tracking feature. This is the default.

#### ***enable\_disable\_clause***

The *enable\_disable\_clause* lets you specify whether Oracle Database should apply a constraint. By default, constraints are created in ENABLE VALIDATE state.

#### **Restrictions on Enabling and Disabling Constraints**

Enabling and disabling constraints are subject to the following restrictions:

- To enable or disable any integrity constraint, you must have defined the constraint in this or a previous statement.
- You cannot enable a foreign key constraint unless the referenced unique or primary key constraint is already enabled.
- In the *index\_properties clause* of the *using\_index\_clause*, the INDEXTYPE IS ... clause is not valid in the definition of a constraint.

#### See Also:

[constraint](#) for more information on constraints and "[Creating a Table: ENABLE/DISABLE Examples](#)"

### **ENABLE Clause**

Use this clause if you want the constraint to be applied to the data in the table. This clause is described fully in "[ENABLE Clause](#)" in the documentation on constraints.

### **DISABLE Clause**

Use this clause if you want to disable the integrity constraint. This clause is described fully in "[DISABLE Clause](#)" in the documentation on constraints.

### **UNIQUE**

The UNIQUE clause lets you enable or disable the unique constraint defined on the specified column or combination of columns.

### **PRIMARY KEY**

The PRIMARY KEY clause lets you enable or disable the primary key constraint defined on the table.

### **CONSTRAINT**

The CONSTRAINT clause lets you enable or disable the integrity constraint named *constraint\_name*.

### **KEEP | DROP INDEX**

This clause lets you either preserve or drop the index Oracle Database has been using to enforce a unique or primary key constraint.

### Restriction on Preserving and Dropping Indexes

You can specify this clause only when disabling a unique or primary key constraint.

#### *using\_index\_clause*

The *using\_index\_clause* lets you specify an index for Oracle Database to use to enforce a unique or primary key constraint, or lets you instruct the database to create the index used to enforce the constraint.

#### See Also:

- [CREATE INDEX](#) for a description of *index\_attributes*, the *global\_partitioned\_index* and *local\_partitioned\_index* clauses, NOSORT, and the *logging\_clause* in relation to indexes
- [constraint](#) for information on the *using\_index\_clause* and on PRIMARY KEY and UNIQUE constraints
- "[Explicit Index Control Example](#)" for an example of using an index to enforce a constraint

## CASCADE

Specify CASCADE to disable any integrity constraints that depend on the specified integrity constraint. To disable a primary or unique key that is part of a referential integrity constraint, you must specify this clause.

### Restriction on CASCADE

You can specify CASCADE only if you have specified DISABLE.

#### *row\_movement\_clause*

The *row\_movement\_clause* lets you specify whether the database can move a table row. It is possible for a row to move, for example, during table compression or an update operation on partitioned data.

#### Note:

If you need static rowids for data access, then do not enable row movement. For a normal (heap-organized) table, moving a row changes the rowid of the row. For a moved row in an index-organized table, the logical rowid remains valid, although the physical guess component of the logical rowid becomes inaccurate.

- Specify ENABLE to allow the database to move a row, thus changing the rowid.
- Specify DISABLE if you want to prevent the database from moving a row, thus preventing a change of rowid.

If you omit this clause, then the database disables row movement.

### Restriction on Row Movement

You cannot specify this clause for a nonpartitioned index-organized table.

#### *logical\_replication\_clause*

Use this clause to perform partial database replication for users such as Oracle GoldenGate, and reduce the supplemental logging overhead of uninteresting tables in interesting schema where supplemental logging is enabled.

### ENABLE LOGICAL REPLICATION

You can specify `ENABLE LOGICAL REPLICATION` with `ALLKEYS`, `ALLOW NOVALIDATE KEYS`, and `[NO] PARTIAL JSON` in any order. The supplemental log settings of all levels (database, the container, schema, table) are honored. No additional ID or scheduling-key supplemental logging is added for this table.

### DISABLE LOGICAL REPLICATION

When logical replication is disabled for a table, it means that only database level supplemental logging is honored. This provides a way for partial database replication users (who will not enable database level column data supplemental logging) to disable supplemental logging for uninteresting tables, so that even when supplemental logging is enabled at the schema level, there is no column data supplemental logging for uninteresting tables.

If you create a table with `DISABLE LOGICAL REPLICATION`, logical replication is disabled for the table. Database and container level supplemental log settings are honored but table-level and schema-level supplemental log settings are ignored.

### ENABLE LOGICAL REPLICATION ALL KEYS

Use this option to enable the table for Golden Gate `AUTO_CAPTURE`.

ID and scheduling keys, primary key (`PK`), foreign key (`FK`), unique index (`UI`), and all key supplemental logging (`ALLKEYS`) are implicitly enabled for the table.

### ENABLE LOGICAL REPLICATION ALLOW NOVALIDATE KEYS

Use this option to enable the table for Golden Gate `AUTO_CAPTURE`.

ID and scheduling keys, primary key (`PK`), foreign key (`FK`), unique index (`UI`), and all key supplemental logging (`ALLKEYS`) are implicitly enabled for the table. The primary key constraint in `NOVALIDATE` mode can be supplementally logged as a unique identifier for the table. `NOVALIDATE KEYS` are allowed as a row identification key.

If you create a table with `ENABLE LOGICAL REPLICATION ALLOW NOVALIDATE KEYS`, ID and scheduling-key is implicitly enabled for the table. The primary key constraint in `NOVALIDATE` mode can be supplementally logged as a unique identifier for the table.

### NO PARTIAL JSON

Use this clause if your replication target database does not support native `JSON`, `partial JSON` or `JSON DIFF`. This includes non-Oracle target databases and Oracle target databases with DB compatible lower than 23.

You can specify `NO PARTIAL JSON` whether a column of type `JSON` exists or not.

When you enable column-level data supplemental logging on the table or schema, `partial JSON` update is disabled. This means that the `JSON` update will always generate a new `JSON` instance with full `JSON` document. This is the default when `[NO] PARTIAL JSON` is not specified.

In order to use `NO PARTIAL JSON` without errors, you must set the database compatible initialization parameter must be set to 23 or higher.

### PARTIAL JSON

Use this option if your replication target database is Oracle Database with the database compatible initialization parameter set to 23 or higher and where `partial JSON` and `JSON DIFF` can be supported at the target database.

You can specify `PARTIAL JSON` whether a column of type `JSON` exists or not.

With `PARTIAL JSON` you can enable a partial `JSON` update for the table. A `JSON` column updated using `JSON_TRANSFORM` may internally partially update the existing `JSON` instance, even when column-level data supplemental logging has been added for the table or schema.

In order to use `PARTIAL JSON` without errors, you must set the database compatible initialization parameter must be set to 23 or higher.

### *flashback\_archive\_clause*

You must have the `FLASHBACK ARCHIVE` object privilege on the specified flashback archive to specify this clause. Use this clause to enable or disable historical tracking for the table.

- Specify `FLASHBACK ARCHIVE` to enable tracking for the table. You can specify `flashback_archive` to designate a particular flashback archive for this table. The flashback archive you specify must already exist.  
If you omit `flashback_archive`, then the database uses the default flashback archive designated for the system. If no default flashback archive has been designated for the system, then you must specify `flashback_archive`.
- Specify `NO FLASHBACK ARCHIVE` to disable tracking for the table. This is the default.

### Restrictions on *flashback\_archive\_clause*

Flashback data archives are subject to the following restrictions:

- You cannot specify this clause for a nested table, clustered table, temporary table, remote table, or external table.
- You cannot specify this clause for a table compressed with Hybrid Columnar Compression.
- The table for which you are specifying this clause cannot contain any `LONG` or nested table columns.
- If you specify this clause and subsequently copy the table to a different database —using the export and import utilities or the transportable tablespace feature— then the copied table will not be enabled for tracking and the archived data for the original table will not be available for the copied table.

 See Also:

- *Oracle Database Development Guide* for general information on using Flashback Time Travel
- [ALTER FLASHBACK ARCHIVE](#) for information on changing the quota and retention attributes of the flashback archive, as well as adding or changing tablespace storage for the flashback archive

**ROW ARCHIVAL**

Specify this clause to enable *table* for row archival. This clause lets you implement In-Database Archiving, which allows you to designate table rows as active or archived. You can then perform queries on only the active rows within the table.

When you specify this clause, a hidden column `ORA_ARCHIVE_STATE` is created in the table. The column is of data type `VARCHAR2`. You can specify a value of `0` or `1` for this column to indicate whether a row is active (`0`) or archived (`1`). If you do not specify a value for `ORA_ARCHIVE_STATE` when inserting data into the table, then the value is set to `0`.

- If `ROW ARCHIVE VISIBILITY = ACTIVE` for the session, then the database will consider only active rows when performing queries on the table.
- If `ROW ARCHIVE VISIBILITY = ALL` for the session, then the database will consider all rows when performing queries on the table.

 See Also:

- The [ALTER SESSION Semantics](#) clause to learn how to configure row archival visibility for a session
- The [ALTER TABLE \[NO\] ROW ARCHIVAL](#) clause to learn how to enable or disable an existing table for row archival
- *Oracle Database VLDB and Partitioning Guide* for more information on In-Database Archiving

**FOR EXCHANGE WITH TABLE**

This clause lets you create a table that matches the structure of an existing partitioned table. The two tables are then eligible for exchanging partitions and subpartitions. For *table*, specify an existing partitioned table. For *schema*, specify the schema that contains the existing partitioned table. If you omit *schema*, then the database assumes the table is in your own schema.

This operation creates a metadata clone, without data, of the partitioned table. The clone has the same column ordering and column properties of the original table. Column properties copied to the clone during this operation include unusable columns, invisible columns, virtual expression columns, functional index expression columns, and other internal settings and attributes. Indexes on the existing partitioned table are not created on the clone table.

You can subsequently use the `exchange_partition_subpart` clause of `ALTER TABLE` to exchange partitions or subpartitions between the two tables. Refer to [exchange\\_partition\\_subpart](#) in the documentation on `ALTER TABLE` for more information.

Each super sharding or sharding key column with a character data type must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.

### Restrictions on FOR EXCHANGE WITH TABLE

The following restrictions apply to the `FOR EXCHANGE WITH TABLE` clause:

- If you specify this clause, then you cannot specify the `relational_properties` clause.
- If you specify this clause, then within the `table_properties` clause, you can specify only the `table_partitioning_clause`.
- Within the `table_partitioning_clause` each key column with a character data type must have one of the following declared collations: `BINARY`, `USING_NLS_COMP`, `USING_NLS_SORT`, or `USING_NLS_SORT_CS`.
- When you create a clone for a partition of a composite-partitioned table, you must explicitly specifying the appropriate `table_partitioning_clause` that matches exactly the subpartitioning of the partition you want to exchange.
- Oracle does not clone the statistics setup of the partitioned table. For example, if you plan to perform an exchange with a partitioned table for which incremental statistics are enabled, you must manually enable the creation of a table synopsis on the clone table. See *Oracle Database SQL Tuning Guide* for more information on maintaining incremental statistics on partitioned tables.
- You cannot create a clone of an external table.
- If the table specified in the `FOR EXCHANGE WITH TABLE` clause is protected by a fine-grained audit (FGA) policy, then the `CREATE TABLE` statement will fail, if the user who is creating it is not the `SYS` user.
- You cannot use this clause if you have VPD policies enabled on the target table.

### AS *subquery*

Specify a subquery to determine the contents of the table. The rows returned by the subquery are inserted into the table upon its creation.

For object tables, *subquery* can contain either one expression corresponding to the table type, or the number of top-level attributes of the table type. Refer to [SELECT](#) for more information.

If *subquery* returns the equivalent of part or all of an existing materialized view, then the database may rewrite the query to use the materialized view in place of one or more tables specified in *subquery*.

 See Also:

*Oracle Database Data Warehousing Guide* for more information on materialized views and query rewrite

Oracle Database derives data types and lengths from the subquery. Oracle Database follows the following rules for integrity constraints and other column and table attributes:

- Oracle Database automatically defines on columns in the new table any NOT NULL constraints that have a state of NOT DEFERRABLE and VALIDATE, and were explicitly created on the corresponding columns of the selected table if the subquery selects the column rather than an expression containing the column. If any rows violate the constraint, then the database does not create the table and returns an error.
- NOT NULL constraints that were implicitly created by Oracle Database on columns of the selected table (for example, for primary keys) are not carried over to the new table.
- In addition, primary keys, unique keys, foreign keys, check constraints, partitioning criteria, indexes, and column default values are not carried over to the new table.
- If the selected table is partitioned, then you can choose whether the new table will be partitioned the same way, partitioned differently, or not partitioned. Partitioning is not carried over to the new table. Specify any desired partitioning as part of the CREATE TABLE statement before the AS *subquery* clause.
- A column that is encrypted using Transparent Data Encryption in the selected table will not be encrypted in the new table unless you define the column in the new table as encrypted at create time.

 Note:

Oracle recommends that you encrypt sensitive columns before populating them with data. This will avoid creating clear text copies of sensitive data.

If each column returned by *subquery* has a column name or is an expression with a specified column alias, then you can omit the columns from the table definition entirely. In this case, the names of the columns of *table* are the same as the columns in *subquery*. The exception is creating an index-organized table, for which you must specify the columns in the table definition because you must specify a primary key column.

You can use *subquery* in combination with the TO\_LOB function to convert the values in a LONG column in another table to LOB values in a column of the table you are creating.

 See Also:

- *Oracle Database SecureFiles and Large Objects Developer's Guide* for a discussion of why and when to copy `LONG` data to a LOB
- "[Conversion Functions](#)" for a description of how to use the `TO_LOB` function
- [SELECT](#) for more information on the `order_by_clause`
- *Oracle Database SQL Tuning Guide* for information on statistics gathering when using the `AS subquery` clause

**`parallel_clause`**

If you specify the `parallel_clause` in this statement, then the database will ignore any value you specify for the `INITIAL` storage parameter and will instead use the value of the `NEXT` parameter.

 See Also:

[storage\\_clause](#) for information on these parameters

**ORDER BY**

The `ORDER BY` clause lets you order rows returned by the subquery.

When specified with `CREATE TABLE`, this clause does not necessarily order data across the entire table. For example, it does not order across partitions. Specify this clause if you intend to create an index on the same key as the `ORDER BY` key column. Oracle Database will cluster data on the `ORDER BY` key so that it corresponds to the index key.

**Restrictions on the Defining Query of a Table**

The table query is subject to the following restrictions:

- The number of columns in the table must equal the number of expressions in the subquery.
- The column definitions can specify only column names, default values, and integrity constraints, not data types.
- You cannot define a foreign key constraint in a `CREATE TABLE` statement that contains `AS subquery` unless the table is reference partitioned and the constraint is the table's partitioning referential constraint. In all other cases, you must create the table without the constraint and then add it later with an `ALTER TABLE` statement.

**FOR STAGING**

Specify `FOR STAGING` to create a staging table optimized for staging data in Oracle Database. Staging tables are typically shortlived and volatile with constantly changing data.

You can create a staging table with or without partitions with `CREATE TABLE t FOR STAGING` or you can convert an existing table into a staging table with `ALTER TABLE t FOR STAGING`.

### Examples: Create a Staging Table

```
CREATE TABLE staging_table (col1 number, col2 varchar2(100)) FOR STAGING;
```

### Examples: Create a Staging Table With Partitions

```
CREATE TABLE part_staging_table (col1 number, col2 varchar2(100))
PARTITION BY RANGE (col1) (PARTITION p1 VALUES LESS THAN (100), PARTITION pmax VALUES
LESS THAN (MAXVALUE))
FOR STAGING;
```

A staging table with or without partitions has the following characteristics:

- Compression is explicitly turned off and disallowed for any future data load on the table and its partitions and subpartitions. Changing existing tables into staging tables will not impact the storage of existing data but only impact future data loads.
- You cannot change the default attributes of a staging table, its partitions or subpartitions, or future data loads using `ALTER TABLE`.
- You cannot perform any partition maintenance operations that will move the data and compress it using `ALTER TABLE`.
- You cannot partition a staging table and specify compression on any of its partitions.
- Dynamic sampling is used for queries on a staging table. This means that you cannot gather statistics on a staging table or any of its partitions.
- If you drop a staging table it will be dropped immediately, bypassing the recyclebin irrespective of your setting.

The dictionary views `USER_TABLES`, `ALL_TABLES`, and `DBA_TABLES` have a `staging` table property in a new column `STAGING`. The value of `STAGING` is `YES` for a staged table, and `NO` otherwise.

### *object\_table*

The `OF` clause lets you explicitly create an **object table** of type `object_type`. The columns of an object table correspond to the top-level attributes of type `object_type`. Each row will contain an object instance, and each instance will be assigned a unique, system-generated object identifier when a row is inserted. If you omit `schema`, then the database creates the object table in your own schema.

Object tables, as well as `XMLType` tables, object views, and `XMLType` views, do not have any column names specified for them. Therefore, Oracle defines a system-generated pseudocolumn `OBJECT_ID`. You can use this column name in queries and to create object views with the `WITH OBJECT IDENTIFIER` clause.

#### See Also:

["Object Column and Table Examples"](#)

### *object\_table\_substitution*

Use the `object_table_substitution` clause to specify whether row objects corresponding to subtypes can be inserted into this object table.

#### NOT SUBSTITUTABLE AT ALL LEVELS

NOT SUBSTITUTABLE AT ALL LEVELS indicates that the object table being created is not substitutable. In addition, substitution is disabled for all embedded object attributes and elements of embedded nested tables and arrays. The default is SUBSTITUTABLE AT ALL LEVELS.

#### See Also:

- [CREATE TYPE](#) for more information about creating object types
- ["User-Defined Types "](#), ["About User-Defined Functions "](#), ["About SQL Expressions "](#), [CREATE TYPE](#), and *Oracle Database Object-Relational Developer's Guide* for more information about using REF types

#### ***object\_properties***

The properties of object tables are essentially the same as those of relational tables. However, instead of specifying columns, you specify attributes of the object.

For `attribute`, specify the qualified column name of an item in an object.

#### ***oid\_clause***

The `oid_clause` lets you specify whether the object identifier of the object table should be system generated or should be based on the primary key of the table. The default is SYSTEM GENERATED.

#### Restrictions on the `oid_clause`

This clause is subject to the following restrictions:

- You cannot specify OBJECT IDENTIFIER IS PRIMARY KEY unless you have already specified a PRIMARY KEY constraint for the table.
- You cannot specify this clause for a nested table.

#### Note:

A primary key object identifier is locally unique but not necessarily globally unique. If you require a globally unique identifier, then you must ensure that the primary key is globally unique.

#### ***oid\_index\_clause***

This clause is relevant only if you have specified the `oid_clause` as SYSTEM GENERATED. It specifies an index, and optionally its storage characteristics, on the hidden object identifier column.

For *index*, specify the name of the index on the hidden system-generated object identifier column. If you omit *index*, then the database generates a name.

#### ***physical\_properties* and *table\_properties***

The semantics of these clauses are documented in the corresponding sections under relational tables. See [physical\\_properties](#) and [table\\_properties](#).

#### ***XMLType\_table***

Use the *XMLType\_table* syntax to create a table of data type `XMLType`. Most of the clauses used to create an `XMLType` table have the same semantics that exist for object tables. The clauses specific to `XMLType` tables are described in this section.

Object tables, as well as `XMLType` tables, object views, and `XMLType` views, do not have any column names specified for them. Therefore, Oracle defines a system-generated pseudocolumn `OBJECT_ID`. You can use this column name in queries and to create object views with the `WITH OBJECT IDENTIFIER` clause.

#### ***XMLSchema\_spec***

This clause lets you specify the URL of a registered XMLSchema, either in the `XMLSHEMA` clause or as part of the `ELEMENT` clause, and an XML element name.

You must specify an element, although the XMLSchema URL is optional. If you do specify an XMLSchema URL, then you must already have registered the XMLSchema using the `DBMS_XMLSHEMA` package.

The optional `STORE ALL VARRAYS AS` clause lets you specify how all varrays in the `XMLType` table or column are to be stored.

- `STORE ALL VARRAYS AS LOBS` indicates that all varrays are to be stored as LOBs.
- `STORE ALL VARRAYS AS TABLES` indicates that all varrays are to be stored as tables.

The optional `ALLOW | DISALLOW` clauses are valid only if you have specified `BINARY XML` storage.

- `ALLOW NONSCHEMA` indicates that non-schema-based documents can be stored in the `XMLType` column.
- `DISALLOW NONSCHEMA` indicates that non-schema-based documents cannot be stored in the `XMLType` column. This is the default.
- `ALLOW ANYSCHEMA` indicates that any schema-based document can be stored in the `XMLType` column.
- `DISALLOW ANYSCHEMA` indicates that any schema-based document cannot be stored in the `XMLType` column. This is the default.

 **See Also:**

### MEMOPTIMIZE FOR READ

Use this clause to enable fast lookup. Fast lookup improves the performance high frequency data query operations. The `MEMOPTIMIZE_POOL_SIZE` initialization parameter controls the size of the memoptimize pool. Note that the feature uses additional memory from the SGA.

- You must specify this clause as a top-level attribute of the table, it cannot be specified at the partition or subpartition level.
- You must explicitly enable the table for `MEMOPTIMIZE FOR READ` before you can read data from the table.

### MEMOPTIMIZE FOR WRITE

Use this clause to enable fast ingest. Fast ingest optimizes memory processing of high frequency single row data inserts from Internet of Things (IoT) applications.

- `MEMOPTIMIZE FOR WRITE` is a top-level attribute and cannot be used at the partition or subpartition level.
- A table must be enabled for `MEMOPTIMIZE FOR WRITE` before data for that table can be written to the IGA.

### Restrictions

Blockchain and immutable tables do not support `MEMOPTIMIZE FOR WRITE`.

Columns of `BFILE` datatype do not support `MEMOPTIMIZE FOR WRITE`.

### PARENT

You can use this clause to create a child table in a sharded table family.

A sharded table family is a set of tables that are sharded in the same way. Corresponding partitions of all tables in a table family are stored in the same shard. This enables you to minimize the number of multishard joins when querying data in the table family.

There are two methods for creating a sharded table family. The recommended method involves using reference partitioning. However, if it is impossible or undesirable to create the primary and foreign key constraints that are required for reference partitioning, then you can use the `PARENT` clause to create a sharded table family.

The rules for creating a sharded table family differ depending on which method you use. When you create a sharded table family by using the `PARENT` clause, the following rules apply:

- The sharded table family can contain only two levels of tables: a parent table, and one or more child tables.
- All tables in the family must be explicitly partitioned using the same partitioning scheme. Each table can use a different subpartitioning scheme, or none at all.
- You must first create the parent table, and it must be a sharded table.
- You can then use the CREATE SHARDED TABLE ... PARENT ... statement to create each child table. For *table*, specify the name of the parent table. For *schema*, specify the schema that contains the parent table. If you omit *schema*, then the database assumes the parent table is in your own schema.

You can create multiple sharded table families with system sharding but at most one with composite or user-defined sharding.

## Examples

### Creating Tables: General Examples

This statement shows how the `employees` table owned by the sample human resources (`hr`) schema was created. A hypothetical name is given to the table and constraints so that you can duplicate this example in your test database:

```
CREATE TABLE employees_demo
  ( employee_id      NUMBER(6)
  , first_name       VARCHAR2(20)
  , last_name        VARCHAR2(25)
    CONSTRAINT emp_last_name_nn_demo NOT NULL
  , email            VARCHAR2(25)
    CONSTRAINT emp_email_nn_demo      NOT NULL
  , phone_number     VARCHAR2(20)
  , hire_date        DATE   DEFAULT SYSDATE
    CONSTRAINT emp_hire_date_nn_demo NOT NULL
  , job_id           VARCHAR2(10)
    CONSTRAINT emp_job_nn_demo      NOT NULL
  , salary            NUMBER(8,2)
    CONSTRAINT emp_salary_nn_demo  NOT NULL
  , commission_pct   NUMBER(2,2)
  , manager_id       NUMBER(6)
  , department_id    NUMBER(4)
  , dn               VARCHAR2(300)
  , CONSTRAINT emp_salary_min_demo
                    CHECK (salary > 0)
  , CONSTRAINT emp_email_uk_demo
                    UNIQUE (email)
  ) ;
```

This table contains twelve columns. The `employee_id` column is of data type `NUMBER`. The `hire_date` column is of data type `DATE` and has a default value of `SYSDATE`. The `last_name` column is of type `VARCHAR2` and has a `NOT NULL` constraint, and so on.

### Creating a Table: Storage Example

To define the same `employees_demo` table in the example tablespace with a small storage capacity, issue the following statement:

```
CREATE TABLE employees_demo
  ( employee_id      NUMBER(6)
  , first_name       VARCHAR2(20)
  , last_name        VARCHAR2(25)
    CONSTRAINT emp_last_name_nn_demo NOT NULL
  , email            VARCHAR2(25)
    CONSTRAINT emp_email_nn_demo      NOT NULL
  , phone_number     VARCHAR2(20)
  , hire_date        DATE DEFAULT SYSDATE
    CONSTRAINT emp_hire_date_nn_demo NOT NULL
  , job_id           VARCHAR2(10)
    CONSTRAINT emp_job_nn_demo      NOT NULL
  , salary            NUMBER(8,2)
    CONSTRAINT emp_salary_nn_demo   NOT NULL
  , commission_pct   NUMBER(2,2)
  , manager_id       NUMBER(6)
  , department_id    NUMBER(4)
  , dn               VARCHAR2(300)
  , CONSTRAINT emp_salary_min_demo
                    CHECK (salary > 0)
  , CONSTRAINT emp_email_uk_demo
                    UNIQUE (email)
  )
TABLESPACE example
STORAGE (INITIAL 8M);
```

### Creating a Table with a DEFAULT ON NULL Column Value: Example

The following statement creates a table `myemp`, which can be used to store employee data. The `department_id` column is defined with a `DEFAULT ON NULL` column value of 50. Therefore, if a subsequent `INSERT` statement attempts to assign a `NONE` value to `department_id`, then the value of 50 will be assigned instead.

```
CREATE TABLE myemp (employee_id number, last_name varchar2(25),
                     department_id NUMBER DEFAULT ON NULL 50 NOT NULL);
```

In the `employees` table, `employee_id` 178 has a `NONE` value for `department_id`:

```
SELECT employee_id, last_name, department_id
  FROM employees
 WHERE department_id IS NULL;
```

| EMPLOYEE_ID | LAST_NAME | DEPARTMENT_ID |
|-------------|-----------|---------------|
| 178         | Grant     |               |

Populate the `myemp` table with the `employee_id`, `last_name`, and `department_id` column data from the `employees` table:

```
INSERT INTO myemp (employee_id, last_name, department_id)
  (SELECT employee_id, last_name, department_id from employees);
```

In the `myemp` table, `employee_id` 178 has a value of 50 for `department_id`:

```
SELECT employee_id, last_name, department_id
  FROM myemp
 WHERE employee_id = 178;
```

| EMPLOYEE_ID | LAST_NAME | DEPARTMENT_ID |
|-------------|-----------|---------------|
| 178         | Grant     | 50            |

### Creating a Table with an Identity Column: Examples

The following statement creates a table `t1` with an identity column `id`. The sequence generator will always assign increasing integer values to `id`, starting with 1.

```
CREATE TABLE t1 (id NUMBER GENERATED AS IDENTITY);
```

The following statement creates a table `t2` with an identity column `id`. The sequence generator will, by default, assign increasing integer values to `id` in increments of 10 starting with 100.

```
CREATE TABLE t2 (id NUMBER GENERATED BY DEFAULT AS IDENTITY (START WITH 100 INCREMENT BY 10));
```

### Creating a Table: Temporary Table Example

The following statement creates a temporary table `today_sales` for use by sales representatives in the sample database. Each sales representative session can store its own sales data for the day in the table. The temporary data is deleted at the end of the session.

```
CREATE GLOBAL TEMPORARY TABLE today_sales
  ON COMMIT PRESERVE ROWS
  AS SELECT * FROM orders WHERE order_date = SYSDATE;
```

### Creating a Table with Deferred Segment Creation: Example

The following statement creates a table with deferred segment creation. Oracle Database will not create a segment for the data of this table until data is inserted into the table:

```
CREATE TABLE later (col1 NUMBER, col2 VARCHAR2(20)) SEGMENT CREATION DEFERRED;
```

### Substitutable Table and Column Examples

The following statements create a type hierarchy, which can be used to create a substitutable table. Type `employee_t` inherits the `name` and `ssn` attributes from type `person_t` and in addition has `department_id` and `salary` attributes. Type `part_time_emp_t` inherits all of the attributes from `employee_t` and, through `employee_t`, those of `person_t` and in addition has a `num_hrs` attribute. Type `part_time_emp_t` is final by default, so no further subtypes can be created under it.

```
CREATE TYPE person_t AS OBJECT (name VARCHAR2(100), ssn NUMBER)
  NOT FINAL;
/

CREATE TYPE employee_t UNDER person_t
  (department_id NUMBER, salary NUMBER) NOT FINAL;
/

CREATE TYPE part_time_emp_t UNDER employee_t (num_hrs NUMBER);
/
```

The following statement creates a substitutable table from the `person_t` type:

```
CREATE TABLE persons OF person_t;
```

The following statement creates a table with a substitutable column of type `person_t`:

```
CREATE TABLE books (title VARCHAR2(100), author person_t);
```

When you insert into persons or books, you can specify values for the attributes of person\_t or any of its subtypes. Examples of insert statements appear in "[Inserting into a Substitutable Tables and Columns: Examples](#)".

You can extract data from such tables using built-in functions and conditions. For examples, see the functions TREAT and SYS\_TYPEID , and the "IS OF type Condition " condition.

### Creating a Table: Parallelism Examples

The following statement creates a table using an optimum number of parallel execution servers to scan employees and to populate dept\_80:

```
CREATE TABLE dept_80
  PARALLEL
  AS SELECT * FROM employees
  WHERE department_id = 80;
```

Using parallelism speeds up the creation of the table, because the database uses parallel execution servers to create the table. After the table is created, querying the table is also faster, because the same degree of parallelism is used to access the table.

The following statement creates the same table serially. Subsequent DML and queries on the table will also be serially executed.

```
CREATE TABLE dept_80
  AS SELECT * FROM employees
  WHERE department_id = 80;
```

### Creating a Table: ENABLE/DISABLE Examples

The following statement shows how the sample table departments was created. The example defines a NOT NULL constraint, and places it in ENABLE VALIDATE state:

```
CREATE TABLE departments_demo
  ( department_id    NUMBER(4)
  , department_name  VARCHAR2(30)
    CONSTRAINT dept_name_nn NOT NULL
  , manager_id       NUMBER(6)
  , location_id      NUMBER(4)
  , dn               VARCHAR2(300)
  ) ;
```

The following statement creates the same departments\_demo table but also defines a disabled primary key constraint:

```
CREATE TABLE departments_demo
  ( department_id    NUMBER(4)    PRIMARY KEY DISABLE
  , department_name  VARCHAR2(30)
    CONSTRAINT dept_name_nn NOT NULL
  , manager_id       NUMBER(6)
  , location_id      NUMBER(4)
  , dn               VARCHAR2(300)
  ) ;
```

### Nested Table Example

The following statement shows how the sample table `pm.print_media` was created with a nested table column `ad_textdocs_ntab`:

```
CREATE TABLE print_media
  ( product_id      NUMBER(6)
  , ad_id          NUMBER(6)
  , ad_composite   BLOB
  , ad_sourcetext  CLOB
  , ad_finaltext   CLOB
  , ad_fltextrn    NCLOB
  , ad_textdocs_ntab textdoc_tab
  , ad_photo        BLOB
  , ad_graphic     BFILE
  , ad_header       adheader_typ
  ) NESTED TABLE ad_textdocs_ntab STORE AS textdocs_nestedtab;
```

### Creating a Table: Multilevel Collection Example

The following example shows how an account manager might create a table of customers using two levels of nested tables:

```
CREATE TYPE phone AS OBJECT (telephone NUMBER);
/
CREATE TYPE phone_list AS TABLE OF phone;
/
CREATE TYPE my_customers AS OBJECT (
  cust_name VARCHAR2(25),
  phones phone_list);
/
CREATE TYPE customer_list AS TABLE OF my_customers;
/
CREATE TABLE business_contacts (
  company_name VARCHAR2(25),
  company_reps customer_list)
  NESTED TABLE company_reps STORE AS outer_ntab
  (NESTED TABLE phones STORE AS inner_ntab);
```

The following variation of this example shows how to use the `COLUMN_VALUE` keyword if the inner nested table has no column or attribute name:

```
CREATE TYPE phone AS TABLE OF NUMBER;
/
CREATE TYPE phone_list AS TABLE OF phone;
/
CREATE TABLE my_customers (
  name VARCHAR2(25),
  phone_numbers phone_list)
  NESTED TABLE phone_numbers STORE AS outer_ntab
  (NESTED TABLE COLUMN_VALUE STORE AS inner_ntab);
```

### Creating a Table: LOB Column Example

The following statement is a variation of the statement that created the `print_media` table with some added LOB storage characteristics:

```
CREATE TABLE print_media_new
  ( product_id      NUMBER(6)
  , ad_id          NUMBER(6)
  , ad_composite   BLOB
  , ad_sourcetext  CLOB
  , ad_finaltext   CLOB
```

```

, ad_fltextrn      NCLOB
, ad_textdocs_ntab textdoc_tab
, ad_photo         BLOB
, ad_graphic       BFILE
, ad_header        adheader_typ
) NESTED TABLE ad_textdocs_ntab STORE AS textdocs_nestedtab_new
LOB (ad_sourcetext, ad_finaltext) STORE AS
  (TABLESPACE example
  STORAGE (INITIAL 6144)
  CHUNK 4000
  NOCACHE LOGGING);

```

In the example above, the database rounds the value of `CHUNK` up to 4096 (the nearest multiple of the block size of 2048).

### Index-Organized Table Example

The following statement is a variation of the sample table `hr.countries`, which is index organized:

```

CREATE TABLE countries_demo
  ( country_id      CHAR(2)
    CONSTRAINT country_id_nn_demo NOT NULL
  , country_name    VARCHAR2(40)
  , currency_name   VARCHAR2(25)
  , currency_symbol VARCHAR2(3)
  , region          VARCHAR2(15)
  , CONSTRAINT      country_c_id_pk_demo
                    PRIMARY KEY (country_id) )
  ORGANIZATION INDEX
  INCLUDING   country_name
  PCTTHRESHOLD 2
  STORAGE
    ( INITIAL 4K )
  OVERFLOW
  STORAGE
    ( INITIAL 4K );

```

### External Table Example

The following statement creates an external table that represents a subset of the sample table `hr.departments`. The `TYPE` clause specifies that the access driver type for the table is `ORACLE_LOADER`. The `ACCESS PARAMETERS()` clause specifies parameter values for the `ORACLE_LOADER` access driver. These parameters are shown in italics and form the `opaque_format_spec`. The syntax for `opaque_format_spec` depends on the access driver type and is outside the scope of this document. Refer to *Oracle Database Utilities* for details on the `ORACLE_LOADER` access driver and the `opaque_format_spec` syntax.

```

CREATE TABLE dept_external (
  deptno     NUMBER(6),
  dname      VARCHAR2(20),
  loc        VARCHAR2(25)
)
ORGANIZATION EXTERNAL
(TYPE oracle_loader
 DEFAULT DIRECTORY admin
 ACCESS PARAMETERS
(
  RECORDS DELIMITED BY newline
)

```

```
BADFILE 'ulcase1.bad'
DISCARDFILE 'ulcase1.dis'
LOGFILE 'ulcase1.log'
SKIP 20
FIELDS TERMINATED BY ","  OPTIONALLY ENCLOSED BY """
(
deptno      INTEGER EXTERNAL(6),
dname       CHAR(20),
loc         CHAR(25)
)
)
LOCATION ('ulcase1.ctl')
)
REJECT LIMIT UNLIMITED;
```

 **See Also:**

["Creating a Directory: Examples"](#) to see how the `admin` directory was created

## XMLType Examples

This section contains brief examples of creating an `XMLType` table or `XMLType` column. For a more expanded version of these examples, refer to "[Using XML in SQL Statements](#)".

### XMLType Table Examples

The following example creates a very simple `XMLType` table with one implicit binary XML column:

```
CREATE TABLE xwarehouses OF XMLTYPE;
```

The following example creates an XMLSchema-based table. The XMLSchema must already have been created (see "[Using XML in SQL Statements](#)" for more information):

```
CREATE TABLE xwarehouses OF XMLTYPE
  XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
  ELEMENT "Warehouse";
```

You can define constraints on an XMLSchema-based table, and you can also create indexes on XMLSchema-based tables, which greatly enhance subsequent queries. You can create object-relational views on `XMLType` tables, and you can create `XMLType` views on object-relational tables.

 **See Also:**

- "[Using XML in SQL Statements](#)" for an example of adding a constraint
- "[Creating an Index on an XMLType Table: Example](#)" for an example of creating an index
- "[Creating an XMLType View: Example](#)" for an example of creating an `XMLType` view

## XMLType Column Examples

The following example creates a table with an XMLType column stored as a CLOB. This table does not require an XMLSchema, so the content structure is not predetermined:

```
CREATE TABLE xwarehouses (
    warehouse_id      NUMBER,
    warehouse_spec    XMLTYPE)
XMLTYPE warehouse_spec STORE AS CLOB
(TABLESPACE example
 STORAGE (INITIAL 6144)
 CHUNK 4000
 NOCACHE LOGGING);
```

The following example creates a similar table, but stores XMLType data in an object relational XMLType column whose structure is determined by the specified schema:

```
CREATE TABLE xwarehouses (
    warehouse_id      NUMBER,
    warehouse_spec    XMLTYPE)
XMLTYPE warehouse_spec STORE AS OBJECT RELATIONAL
    XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
    ELEMENT "Warehouse";
```

The following example creates another similar table with an XMLType column stored as a SecureFiles CLOB. This table does not require an XMLSchema, so the content structure is not predetermined. SecureFiles LOBs require a tablespace with automatic segment-space management, so the example uses the tablespace created in ["Specifying Segment Space Management for a Tablespace: Example"](#).

```
CREATE TABLE xwarehouses (
    warehouse_id      NUMBER,
    warehouse_spec    XMLTYPE)
XMLTYPE warehouse_spec STORE AS SECUREFILE CLOB
(TABLESPACE auto_seg_ts
 STORAGE (INITIAL 6144)
 CACHE);
```

## Partitioning Examples

### Range Partitioning Example

The `sales` table in the sample schema `sh` is partitioned by range. The following example shows an abbreviated variation of the `sales` table. Constraints and storage elements have been omitted from the example.

```
CREATE TABLE range_sales
( prod_id      NUMBER(6)
, cust_id      NUMBER
, time_id      DATE
, channel_id   CHAR(1)
, promo_id     NUMBER(6)
, quantity_sold NUMBER(3)
, amount_sold   NUMBER(10,2)
)
PARTITION BY RANGE (time_id)
(PARTITION SALES_Q1_1998 VALUES LESS THAN (TO_DATE('01-APR-1998','DD-MON-YYYY')),
 PARTITION SALES_Q2_1998 VALUES LESS THAN (TO_DATE('01-JUL-1998','DD-MON-YYYY')),
 PARTITION SALES_Q3_1998 VALUES LESS THAN (TO_DATE('01-OCT-1998','DD-MON-YYYY')),
 PARTITION SALES_Q4_1998 VALUES LESS THAN (TO_DATE('01-JAN-1999','DD-MON-YYYY')),
 PARTITION SALES_Q1_1999 VALUES LESS THAN (TO_DATE('01-APR-1999','DD-MON-YYYY')),
 PARTITION SALES_Q2_1999 VALUES LESS THAN (TO_DATE('01-JUL-1999','DD-MON-YYYY')),
 PARTITION SALES_Q3_1999 VALUES LESS THAN (TO_DATE('01-OCT-1999','DD-MON-YYYY')),
```

```
PARTITION SALES_Q4_1999 VALUES LESS THAN (TO_DATE('01-JAN-2000','DD-MON-YYYY')),  
PARTITION SALES_Q1_2000 VALUES LESS THAN (TO_DATE('01-APR-2000','DD-MON-YYYY')),  
PARTITION SALES_Q2_2000 VALUES LESS THAN (TO_DATE('01-JUL-2000','DD-MON-YYYY')),  
PARTITION SALES_Q3_2000 VALUES LESS THAN (TO_DATE('01-OCT-2000','DD-MON-YYYY')),  
PARTITION SALES_Q4_2000 VALUES LESS THAN (MAXVALUE))  
;
```

For information about partitioned table maintenance operations, see *Oracle Database VLDB and Partitioning Guide*.

### Range Partitioning Live SQL Example

The following statement creates a table partitioned by range:

```
CREATE TABLE empl_h  
(  
    employee_id NUMBER(6) PRIMARY KEY,  
    first_name VARCHAR2(20),  
    last_name VARCHAR2(25),  
    email VARCHAR2(25),  
    phone_number VARCHAR2(20),  
    hire_date DATE DEFAULT SYSDATE,  
    job_id VARCHAR2(10),  
    salary NUMBER(8, 2),  
    part_name VARCHAR2(25)  
) PARTITION BY RANGE (hire_date) (  
PARTITION hire_q1 VALUES less than(to_date('01-APR-2014', 'DD-MON-YYYY')),  
PARTITION hire_q2 VALUES less than(to_date('01-JUL-2014', 'DD-MON-YYYY')),  
PARTITION hire_q3 VALUES less than(to_date('01-OCT-2014', 'DD-MON-YYYY')),  
PARTITION hire_q4 VALUES less than(to_date('01-JAN-2015', 'DD-MON-YYYY'))  
);
```

The following statements insert rows into the partitions:

```
INSERT INTO empl_h (employee_id, first_name, last_name, email, phone_number,  
hire_date, job_id, salary, Part_name)  
VALUES (1, 'Jane', 'Doe', 'example.com', '415.555.0100', '10-Feb-2014', '1001',  
5001,'HIRE_Q1');  
  
INSERT INTO empl_h (employee_id, first_name, last_name, email, phone_number,  
hire_date, job_id, salary, Part_name)  
VALUES (2, 'John', 'Doe', 'example.net', '415.555.0101', '10-Apr-2014', '1002',  
7001,'HIRE_Q2');  
  
INSERT INTO empl_h (employee_id, first_name, last_name, email, phone_number,  
hire_date, job_id, salary, Part_name)  
VALUES (3, 'Isabelle', 'Owl', 'example.org', '415.555.0102', '10-Sep-2014', '1003',  
10001,'HIRE_Q3');  
  
INSERT INTO empl_h (employee_id, first_name, last_name, email, phone_number,  
hire_date, job_id, salary, Part_name)  
VALUES (4, 'Smith', 'Jones', 'example.in', '415.555.0103', '10-Dec-2014', '1004',  
12001,'HIRE_Q4');
```

The following statements display the partition names using data dictionary tables:

```
SELECT PARTITION_NAME FROM USER_TAB_PARTITIONS WHERE TABLE_NAME = 'EMPL_H';
```

| PARTITION_NAME |
|----------------|
| -----          |
| HIRE_Q1        |
| HIRE_Q2        |

```

HIRE_Q3
HIRE_Q4

SELECT TABLE_NAME, PARTITIONING_TYPE, STATUS FROM USER_PART_TABLES WHERE
TABLE_NAME = 'EMPL_H';

TABLE_NAME      PARTITIONING_TYPE      STATUS
-----          -----          -----
EMPL_H          RANGE          VALID

```

The following statement creates a table named `parts` by selecting a particular column from the data dictionary table `user_tab_partitions`:

```
CREATE TABLE parts (p_name) AS SELECT PARTITION_NAME FROM USER_TAB_PARTITIONS
WHERE TABLE_NAME = 'EMPL_H';
```

The following statement displays the table data:

```
select * from parts;
```

```

P_NAME
-----
HIRE_Q1
HIRE_Q2
HIRE_Q3
HIRE_Q4

```

The following statement compares the columns from the two tables and displays the information based on the comparison:

```
select E.HIRE_DATE,E.JOB_ID,P.p_name from empl_h E, parts P where E.Part_name =
P.p_name;

HIRE_DATE JOB_ID      P_NAME
-----      -----
10-FEB-14 1001      HIRE_Q1
10-APR-14 1002      HIRE_Q2
10-SEP-14 1003      HIRE_Q3
10-DEC-14 1004      HIRE_Q4

```

### Interval Partitioning Example

The following example creates a variation of the `oe.customers` table that is partitioned by interval on the `credit_limit` column. One range partition is created to establish the transition point. All of the original data in the table is within the bounds of the range partition. Then data is added that exceeds the range partition, and the database creates a new interval partition.

```

CREATE TABLE customers_demo (
    customer_id number(6),
    cust_first_name varchar2(20),
    cust_last_name varchar2(20),
    credit_limit number(9,2))
PARTITION BY RANGE (credit_limit)
INTERVAL (1000)
(PARTITION p1 VALUES LESS THAN (5001));

INSERT INTO customers_demo
    (customer_id, cust_first_name, cust_last_name, credit_limit)
    (select customer_id, cust_first_name, cust_last_name, credit_limit
     from customers);

```

Query the `USER_TAB_PARTITIONS` data dictionary view before the database creates the interval partition:

```
SELECT partition_name, high_value FROM user_tab_partitions WHERE table_name = 'CUSTOMERS_DEMO';
```

| PARTITION_NAME | HIGH_VALUE |
|----------------|------------|
| P1             | 5001       |

Insert data into the table that exceeds the high value of the range partition:

```
INSERT INTO customers_demo
VALUES (699, 'Fred', 'Flintstone', 5500);
```

Query the `USER_TAB_PARTITIONS` view again after the insert to learn the system-generated name of the interval partition created to accommodate the inserted data. (The system-generated name will vary for each session.)

```
SELECT partition_name, high_value FROM user_tab_partitions
WHERE table_name = 'CUSTOMERS_DEMO'
ORDER BY partition_name;
```

| PARTITION_NAME | HIGH_VALUE |
|----------------|------------|
| P1             | 5001       |
| SYS_P44        | 6001       |

### List Partitioning Example

The following statement shows how the sample table `oe.customers` might have been created as a list-partitioned table. Some columns and all constraints of the sample table have been omitted in this example.

```
CREATE TABLE list_customers
( customer_id          NUMBER(6)
, cust_first_name      VARCHAR2(20)
, cust_last_name       VARCHAR2(20)
, cust_address         CUST_ADDRESS_TYP
, nls_territory        VARCHAR2(30)
, cust_email           VARCHAR2(40))
PARTITION BY LIST (nls_territory) (
PARTITION asia VALUES ('CHINA', 'THAILAND'),
PARTITION europe VALUES ('GERMANY', 'ITALY', 'SWITZERLAND'),
PARTITION west VALUES ('AMERICA'),
PARTITION east VALUES ('INDIA'),
PARTITION rest VALUES (DEFAULT));
```

### Partitioned Table with LOB Columns Example

This statement creates a partitioned table `print_media_demo` with two partitions `p1` and `p2`, and a number of LOB columns. The statement uses the sample table `pm.print_media`.

```
CREATE TABLE print_media_demo
( product_id NUMBER(6)
, ad_id NUMBER(6)
, ad_composite BLOB
, ad_sourcetext CLOB
, ad_finaltext CLOB
, ad_ftextn NCLOB
```

```

, ad_textdocs_ntab textdoc_tab
, ad_photo BLOB
, ad_graphic BFILE
, ad_header adheader_typ
) NESTED TABLE ad_textdocs_ntab STORE AS textdocs_nestedtab_demo
  LOB (ad_composite, ad_photo, ad_finaltext)
  STORE AS (STORAGE (INITIAL 20M))
PARTITION BY RANGE (product_id)
  (PARTITION p1 VALUES LESS THAN (3000) TABLESPACE tbs_01
    LOB (ad_composite, ad_photo)
    STORE AS (TABLESPACE tbs_02 STORAGE (INITIAL 10M))
    NESTED TABLE ad_textdocs_ntab STORE AS nt_p1 (TABLESPACE example),
    PARTITION P2 VALUES LESS THAN (MAXVALUE)
      LOB (ad_composite, ad_finaltext)
      STORE AS SECUREFILE (TABLESPACE auto_seg_ts)
      NESTED TABLE ad_textdocs_ntab STORE AS nt_p2
    )
  TABLESPACE tbs_03;

```

Partition p1 will be in tablespace tbs\_01. The LOB data partitions for ad\_composite and ad\_photo will be in tablespace tbs\_02. The LOB data partition for the remaining LOB columns will be in tablespace tbs\_01. The storage attribute INITIAL is specified for LOB columns ad\_composite and ad\_photo. Other attributes will be inherited from the default table-level specification. The default LOB storage attributes not specified at the table level will be inherited from the tablespace tbs\_02 for columns ad\_composite and ad\_photo and from tablespace tbs\_01 for the remaining LOB columns. LOB index partitions will be in the same tablespaces as the corresponding LOB data partitions. Other storage attributes will be based on values of the corresponding attributes of the LOB data partitions and default attributes of the tablespace where the index partitions reside. The nested table partition for ad\_textdocs\_ntab will be stored as nt\_p1 in tablespace example.

Partition p2 will be in the default tablespace tbs\_03. The LOB data for ad\_composite and ad\_finaltext will be in tablespace auto\_seg\_ts as SecureFiles LOBs. The LOB data for the remaining LOB columns will be in tablespace tbs\_03. The LOB index for columns ad\_composite and ad\_finaltext will be in tablespace auto\_seg\_ts. The LOB index for the remaining LOB columns will be in tablespace tbs\_03. The nested table partition for ad\_textdocs\_ntab will be stored as nt\_p2 in the default tablespace tbs\_03.

### Hash Partitioning Example

The sample table oe.product\_information is not partitioned. However, you might want to partition such a large table by hash for performance reasons, as shown in this example. The tablespace names are hypothetical in this example.

```

CREATE TABLE hash_products
( product_id          NUMBER(6)    PRIMARY KEY
, product_name        VARCHAR2(50)
, product_description VARCHAR2(2000)
, category_id         NUMBER(2)
, weight_class         NUMBER(1)
, warranty_period     INTERVAL YEAR TO MONTH
, supplier_id          NUMBER(6)
, product_status       VARCHAR2(20)
, list_price           NUMBER(8,2)
, min_price            NUMBER(8,2)
, catalog_url          VARCHAR2(50)
, CONSTRAINT           product_status_lov_demo

```

```

        CHECK (product_status in ('orderable'
                                , 'planned'
                                , 'under development'
                                , 'obsolete'))
    )
PARTITION BY HASH (product_id)
PARTITIONS 4
STORE IN (tbs_01, tbs_02, tbs_03, tbs_04);

```

### Reference Partitioning Example

The next statement uses the `hash_products` partitioned table created in the preceding example. It creates a variation of the `oe.order_items` table that is partitioned by reference to the hash partitioning on the product id of `hash_products`. The resulting child table will be created with five partitions. For each row of the child table `part_order_items`, the database evaluates the foreign key value (`product_id`) to determine the partition number of the parent table `hash_products` to which the referenced key belongs. The `part_order_items` row is placed in its corresponding partition.

```

CREATE TABLE part_order_items (
    order_id      NUMBER(12) PRIMARY KEY,
    line_item_id  NUMBER(3),
    product_id    NUMBER(6) NOT NULL,
    unit_price    NUMBER(8,2),
    quantity      NUMBER(8),
    CONSTRAINT product_id_fk
    FOREIGN KEY (product_id) REFERENCES hash_products(product_id))
PARTITION BY REFERENCE (product_id_fk);

```

### Composite-Partitioned Table Examples

The table created in the "Range Partitioning Example" divides data by time of sale. If you plan to access recent data according to distribution channel as well as time, then composite partitioning might be more appropriate. The following example creates a copy of that `range_sales` table but specifies range-hash composite partitioning. The partitions with the most recent data are subpartitioned with both system-generated and user-defined subpartition names. Constraints and storage attributes have been omitted from the example.

```

CREATE TABLE composite_sales
(
    prod_id      NUMBER(6)
    , cust_id     NUMBER
    , time_id     DATE
    , channel_id  CHAR(1)
    , promo_id    NUMBER(6)
    , quantity_sold NUMBER(3)
    , amount_sold   NUMBER(10,2)
)
PARTITION BY RANGE (time_id)
SUBPARTITION BY HASH (channel_id)
(PARTITION SALES_Q1_1998 VALUES LESS THAN (TO_DATE('01-APR-1998','DD-MON-YYYY')),
 PARTITION SALES_Q2_1998 VALUES LESS THAN (TO_DATE('01-JUL-1998','DD-MON-YYYY')),
 PARTITION SALES_Q3_1998 VALUES LESS THAN (TO_DATE('01-OCT-1998','DD-MON-YYYY')),
 PARTITION SALES_Q4_1998 VALUES LESS THAN (TO_DATE('01-JAN-1999','DD-MON-YYYY')),
 PARTITION SALES_Q1_1999 VALUES LESS THAN (TO_DATE('01-APR-1999','DD-MON-YYYY')),
 PARTITION SALES_Q2_1999 VALUES LESS THAN (TO_DATE('01-JUL-1999','DD-MON-YYYY')),
 PARTITION SALES_Q3_1999 VALUES LESS THAN (TO_DATE('01-OCT-1999','DD-MON-YYYY')),
 PARTITION SALES_Q4_1999 VALUES LESS THAN (TO_DATE('01-JAN-2000','DD-MON-YYYY')),
 PARTITION SALES_Q1_2000 VALUES LESS THAN (TO_DATE('01-APR-2000','DD-MON-YYYY')),
 PARTITION SALES_Q2_2000 VALUES LESS THAN (TO_DATE('01-JUL-2000','DD-MON-YYYY'))
)
SUBPARTITIONS 8;

```

```

PARTITION SALES_Q3_2000 VALUES LESS THAN (TO_DATE('01-OCT-2000','DD-MON-YYYY'))
  (SUBPARTITION ch_c,
   SUBPARTITION ch_i,
   SUBPARTITION ch_p,
   SUBPARTITION ch_s,
   SUBPARTITION ch_t),
PARTITION SALES_Q4_2000 VALUES LESS THAN (MAXVALUE)
  SUBPARTITIONS 4)
;

```

The following examples creates a partitioned table of customers based on the sample table oe.customers. In this example, the table is partitioned on the credit\_limit column and list subpartitioned on the nls\_territory column. The subpartition template determines the subpartitioning of any subsequently added partitions, unless you override the template by defining individual subpartitions. This composite partitioning makes it possible to query the table based on a credit limit range within a specified region:

```

CREATE TABLE customers_part (
    customer_id      NUMBER(6),
    cust_first_name  VARCHAR2(20),
    cust_last_name   VARCHAR2(20),
    nls_territory    VARCHAR2(30),
    credit_limit     NUMBER(9,2))
PARTITION BY RANGE (credit_limit)
SUBPARTITION BY LIST (nls_territory)
  SUBPARTITION TEMPLATE
    (SUBPARTITION east VALUES
      ('CHINA', 'JAPAN', 'INDIA', 'THAILAND'),
      SUBPARTITION west VALUES
        ('AMERICA', 'GERMANY', 'ITALY', 'SWITZERLAND'),
        SUBPARTITION other VALUES (DEFAULT))
(PARTITION p1 VALUES LESS THAN (1000),
 PARTITION p2 VALUES LESS THAN (2500),
 PARTITION p3 VALUES LESS THAN (MAXVALUE));

```

## Object Column and Table Examples

### Creating Object Tables: Examples

Consider object type department\_typ:

```

CREATE TYPE department_typ AS OBJECT
  ( d_name  VARCHAR2(100),
    d_address VARCHAR2(200) );
/

```

Object table departments\_obj\_t holds department objects of type department\_typ:

```
CREATE TABLE departments_obj_t OF department_typ;
```

The following statement creates object table salesreps with a user-defined object type, salesrep\_typ:

```

CREATE OR REPLACE TYPE salesrep_typ AS OBJECT
  ( repId NUMBER,
    repName VARCHAR2(64));

CREATE TABLE salesreps OF salesrep_typ;

```

**Creating a Table with a User-Defined Object Identifier: Example**

This example creates an object type and a corresponding object table whose object identifier is primary key based:

```
CREATE TYPE employees_typ AS OBJECT
  (e_no NUMBER, e_address CHAR(30));
/
CREATE TABLE employees_obj_t OF employees_typ (e_no PRIMARY KEY)
  OBJECT IDENTIFIER IS PRIMARY KEY;
```

You can subsequently reference the `employees_obj_t` object table using either `inline_ref_constraint` or `out_of_line_ref_constraint` syntax:

```
CREATE TABLE departments_t
  (d_no      NUMBER,
   mgr_ref REF employees_typ SCOPE IS employees_obj_t);

CREATE TABLE departments_t (
  d_no NUMBER,
  mgr_ref REF employees_typ
  CONSTRAINT mgr_in_emp REFERENCES employees_obj_t);
```

**Specifying Constraints on Type Columns: Example**

The following example shows how to define constraints on attributes of an object type column:

```
CREATE TYPE address_t AS OBJECT
  ( hno      NUMBER,
    street   VARCHAR2(40),
    city     VARCHAR2(20),
    zip      VARCHAR2(5),
    phone    VARCHAR2(10) );
/
CREATE TYPE person AS OBJECT
  ( name      VARCHAR2(40),
    dateofbirth DATE,
    homeaddress address_t,
    manager    REF person );
/
CREATE TABLE persons OF person
  ( homeaddress NOT NULL,
    UNIQUE (homeaddress.phone),
    CHECK (homeaddress.zip IS NOT NULL),
    CHECK (homeaddress.city <> 'San Francisco') );
```

**Add Annotations at Table Creation: Example**

The following example adds two operations with values `Sort` and `Group`, and a standalone `Hidden` without a value, to table table `t1`.

```
CREATE TABLE t1 (T NUMBER) ANNOTATIONS(Operations 'Sort', Operations 'Group', Hidden);
```

The annotation can be preceded by the keyword `ADD` which is the default operation if nothing is specified as the following example shows:

```
CREATE TABLE t1 (T NUMBER) ANNOTATIONS (ADD Hidden);
```

## Add Annotations to Table Columns

```
CREATE TABLE t1 (T NUMBER ANNOTATIONS(Operations 'Sort' , Hidden) );
```

## Add Annotations to Table and Columns

```
CREATE TABLE Employee (
    Id NUMBER(5) ANNOTATIONS(Identity, Display 'Employee ID', Group 'Emp_Info'),
    Ename VARCHAR2(50) ANNOTATIONS(Display 'Employee Name', Group 'Emp_Info'),
    Sal NUMBER TAG ANNOTATIONS(Display 'Employee Salary', UI_Hidden)
) ANNOTATIONS (Display 'Employee Table');
```

## Associating Table Columns to Domains Using CREATE TABLE: Example

You can associate table columns with a domain with `CREATE TABLE` or with `ALTER TABLE MODIFY`.

You must specify domain associations at the end of the statement, after all columns have been defined.

The `DOMAIN` keyword, when specified, must be followed by the domain name.

## Associate Table Columns With a Domain: Example

The following example creates domain `dn1`:

```
CREATE DOMAIN dn1 AS NUMBER;
```

The following example creates domain `dn2`:

```
CREATE DOMAIN dn2 AS (c1 AS NUMBER NOT NULL, c2 as NUMBER DEFAULT 1);
```

The following example creates domain `dm1`:

```
CREATE DOMAIN dm1 AS
(ann AS NUMBER NOT NULL ,
 bnnpos AS NUMBER NOT NULL CONSTRAINT CHECK (bnnpos > 0),
 c AS VARCHAR2(10) DEFAULT 'abc',
 ddon AS NUMBER DEFAULT ON NULL 10)
CONSTRAINT CHECK (ann+ddon < = 100)
CONSTRAINT CHECK (length(c) > bnnpos);
```

The following example associates columns `c1, c2, c3, c4` with domain `dm1`, columns `c5` and `c6` with domain `dn2`, and column `c7` with `dn1`.

```
CREATE TABLE tm1 (c1 NUMBER, c2 NUMBER, c3 VARCHAR2(15),c4 NUMBER, c5 NUMBER,
                  c6 NUMBER, c7 NUMBER, DOMAIN dm1 (c1, c2, c3, c4),
                  DOMAIN dn2(c5, c6), DOMAIN dn1(c7));
```

## Create Tables and Columns as Transportable Binary XML

### Create Tables Stored as Transportable Binary XML

```
CREATE TABLE t1 OF XMLTYPE
  XMLTYPE STORE AS TRANSPORTABLE BINARY XML;
```

### Create Columns Stored as Transportable Binary XML

```
CREATE TABLE t2 (id NUMBER, doc XMLTYPE)
    XMLTYPE doc STORE AS TRANSPORTABLE BINARY XML;
```

### Add Columns Stored as Transportable Binary XML to Tables

```
ALTER TABLE t3 ADD (doc XMLTYPE)
    XMLTYPE doc STORE AS TRANSPORTABLE BINARY XML;
```

## CREATE TABLESPACE

### Purpose

Use the `CREATE TABLESPACE` statement to create a **tablespace**, which is an allocation of space in the database that can contain schema objects.

- A **permanent tablespace** contains persistent schema objects. Objects in permanent tablespaces are stored in **data files**.
- An **undo tablespace** is a type of permanent tablespace used by Oracle Database to manage undo data if you are running your database in automatic undo management mode. Oracle strongly recommends that you use automatic undo management mode rather than using rollback segments for undo.
- A **temporary tablespace** contains schema objects only for the duration of a session. Objects in temporary tablespaces are stored in **temp files**.

When you create a tablespace, it is initially a read/write tablespace. You can subsequently use the `ALTER TABLESPACE` statement to take the tablespace offline or online, add data files or temp files to it, or make it a read-only tablespace.

You can also drop a tablespace from the database with the `DROP TABLESPACE` statement.

#### See Also:

- [Oracle Database Concepts](#) for information on tablespaces
- [ALTER TABLESPACE](#) and [DROP TABLESPACE](#) for information on modifying and dropping tablespaces

### Prerequisites

You must have the `CREATE TABLESPACE` system privilege. To create the `SYSAUX` tablespace, you must have the `SYSDBA` system privilege.

Before you can create a tablespace, you must create a database to contain it, and the database must be open.

#### See Also:

[CREATE DATABASE](#)

To use objects in a tablespace other than the `SYSTEM` tablespace:

- If you are running the database in automatic undo management mode, then at least one `UNDO` tablespace must be online.
- If you are running the database in manual undo management mode, then at least one rollback segment other than the `SYSTEM` rollback segment must be online.

 **Note:**

Oracle strongly recommends that you run your database in automatic undo management mode. For more information, refer to *Oracle Database Administrator's Guide*.

## Syntax

`create_tablespace ::=`

(`permanent_tablespace_clause ::=`, `temporary_tablespace_clause ::=`,  
`undo_tablespace_clause ::=`)

`permanent_tablespace_clause ::=`

(`file_specification ::=`, `permanent_tablespace_attrs ::=`)

*permanent\_tablespace\_attrs ::=*

(*size\_clause ::=*, *logging\_clause ::=*, *tablespace\_encryption\_clause ::=*,  
*default\_tablespace\_params ::=*, *extent\_management\_clause ::=*,  
*segment\_management\_clause ::=*, *flashback\_mode\_clause ::=*)

*logging\_clause ::=*

*tablespace\_encryption\_clause ::=*

(*tablespace\_encryption\_spec ::=*)

*tablespace\_encryption\_spec ::=*

**default\_tablespace\_params ::=**

(`default_table_compression ::=`, `default_index_compression ::=`, `inmemory_clause ::=`,  
`ilm_clause ::=`—part of CREATE TABLE syntax, `storage_clause ::=`)

**Note:**

If you specify the `DEFAULT` clause, then you must specify at least one of the clauses `default_table_compression`, `default_index_compression`, `inmemory_clause`, `ilm_clause`, or `storage_clause`.

**default\_table\_compression ::=**

**default\_index\_compression ::=**

**inmemory\_clause ::=**

*inmemory\_attributes ::=*

(*inmemory\_memcompress ::=, inmemory\_priority ::=, inmemory\_distribute\_tablespace ::=, inmemory\_duplicate ::=*)

*inmemory\_memcompress ::=*

*inmemory\_priority ::=*

*inmemory\_distribute\_tablespace ::=*

*inmemory\_duplicate::=*

*extent\_management\_clause ::=*

(*size\_clause ::=*)

*segment\_management\_clause ::=*

*flashback\_mode\_clause ::=*

*undo\_tablespace\_clause ::=*

(*file\_specification ::=*, *extent\_management\_clause ::=*, *tablespace\_retention\_clause ::=*)

*tablespace\_retention\_clause ::=*

*temporary\_tablespace\_clause ::=*

(*file\_specification ::=*, *tablespace\_group\_clause ::=*, *extent\_management\_clause ::=*, *tablespace\_encryption\_clause ::=*)

*tablespace\_group\_clause ::=*

*lost\_write\_protection ::=*

### Semantics

#### BIGFILE | SMALLFILE

Use this clause to determine whether the tablespace is a bigfile or smallfile tablespace. This clause overrides any default tablespace type setting for the database.

- A **bigfile tablespace** contains only one data file or temp file, which can contain up to approximately 4 billion ( $2^{32}$ ) blocks. The minimum size of the single data file or temp file is 12 megabytes (MB) for a tablespace with 32K blocks and 7MB for a tablespace with 8K blocks. The maximum size of the single data file or temp file is 128 terabytes (TB) for a tablespace with 32K blocks and 32TB for a tablespace with 8K blocks.
- A **smallfile tablespace** is a traditional Oracle tablespace, which can contain 1022 data files or temp files, each of which can contain up to approximately 4 million ( $2^{22}$ ) blocks.

If you omit this clause, then Oracle Database uses the current default tablespace type of permanent or temporary tablespace that is set for the database. If you specify `BIGFILE` for a permanent tablespace, then the database by default creates a locally managed tablespace with automatic segment-space management.

#### Restriction on Bigfile Tablespace

You can specify only one data file in the `DATAFILE` clause or one temp file in the `TEMPFILE` clause.

#### See Also:

- *Oracle Database Administrator's Guide* for more information on using bigfile tablespaces
- "[Creating a Bigfile Tablespace: Example](#)"

#### `permanent_tablespace_clause`

Use the following clauses to create a permanent tablespace. (Some of these clauses are also used to create a temporary or undo tablespace.)

#### `tablespace`

Specify the name of the tablespace to be created. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)".

#### `IF NOT EXISTS`

Specifying `IF NOT EXISTS` has the following effects:

- If the tablespace does not exist, a new tablespace is created at the end of the statement.
- If the tablespace exists, this is the tablespace you have at the end of the statement. A new one is not created because the older one is detected.

Using `IF EXISTS` with `CREATE` results in error: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

#### Note on the `SYSAUX` Tablespace

`SYSAUX` is a required auxiliary system tablespace. You must use the `CREATE TABLESPACE` statement to create the `SYSAUX` tablespace if you are upgrading from a release earlier than Oracle Database 11g. You must have the `SYSDBA` system privilege to specify this clause, and you must have opened the database in `UPGRADE` mode.

You must specify EXTENT MANAGEMENT LOCAL and SEGMENT SPACE MANAGEMENT AUTO for the SYSAUX tablespace. The DATAFILE clause is optional only if you have enabled Oracle Managed Files. See "[DATAFILE | TEMPFILE Clause](#)" for the behavior of the DATAFILE clause.

Take care to allocate sufficient space for the SYSAUX tablespace. For guidelines on creating this tablespace, refer to *Oracle Database Upgrade Guide*.

### Restrictions on the SYSAUX Tablespace

You cannot specify OFFLINE or TEMPORARY for the SYSAUX tablespace.

### DATAFILE | TEMPFILE Clause

Specify the data files to make up the permanent tablespace or the temp files to make up the temporary tablespace. Use the *datafile\_tempfile\_spec* form of *file\_specification* to create regular data files and temp files in an operating system file system or to create Oracle Automatic Storage Management (Oracle ASM) disk group files.

You must specify the DATAFILE or TEMPFILE clause unless you have enabled Oracle Managed Files by setting a value for the DB\_CREATE\_FILE\_DEST initialization parameter. For Oracle ASM disk group files, the parameter must be set to a multiple file creation form of Oracle ASM filenames. If this parameter is set, then the database creates a system-named 100 MB file in the default file destination specified in the parameter. The file has AUTOEXTEND enabled and an unlimited maximum size.

#### Note:

Media recovery does not recognize temp files.

#### See Also:

- *Oracle Automatic Storage Management Administrator's Guide* for more information on using Oracle ASM
- *file\_specification* for a full description, including the AUTOEXTEND parameter and the multiple file creation form of Oracle ASM filenames

### Notes on Specifying Data Files and Temp Files

- You can create a tablespace within an Oracle ASM disk group by providing only the disk group name in the *datafile\_tempfile\_spec*. In this case, Oracle ASM creates a data file in the specified disk group with a system-generated filename. The data file is auto-extensible with an unlimited maximum size and a default size of 100 MB. You can use the *autoextend\_clause* to override the default size.
- If you use one of the reference forms of the *ASM\_filename*, which refers to an existing file, then you must also specify REUSE.

 **Note:**

On some operating systems, Oracle does not allocate space for a temp file until the temp file blocks are actually accessed. This delay in space allocation results in faster creation and resizing of temp files, but it requires that sufficient disk space is available when the temp files are later used. To avoid potential problems, before you create or resize a temp file, ensure that the available disk space exceeds the size of the new temp file or the increased size of a resized temp file. The excess space should allow for anticipated increases in disk space use by unrelated operations as well. Then proceed with the creation or resizing operation.

 **See Also:**

- [file\\_specification](#) for a full description, including the `AUTOEXTEND` parameter
- "Enabling Autoextend for a Tablespace: Example" and "Creating Oracle Managed Files: Examples"

**`permanent_tablespace_attrs`**

Use the `permanent_tablespace_attrs` clauses to set the attributes of the tablespace.

**MINIMUM EXTENT Clause**

This clause is valid only for a dictionary-managed tablespace. Specify the minimum size of an extent in the tablespace. This clause lets you control free space fragmentation in the tablespace by ensuring that the size of every used or free extent in a tablespace is at least as large as, and is a multiple of, the value specified in the `size_clause`.

 **See Also:**

[size\\_clause](#) for information on that clause and *Oracle Database VLDB and Partitioning Guide* for more information about using `MINIMUM EXTENT` to control fragmentation

**BLOCKSIZE Clause**

Use the `BLOCKSIZE` clause to specify a nonstandard block size for the tablespace. In order to specify this clause, the `DB_CACHE_SIZE` and at least one `DB_nK_CACHE_SIZE` parameter must be set, and the integer you specify in this clause must correspond with the setting of one `DB_nK_CACHE_SIZE` parameter setting.

**Restriction on BLOCKSIZE**

You cannot specify nonstandard block sizes for a temporary tablespace or if you intend to assign this tablespace as the temporary tablespace for any users.

**Note:**

Oracle recommend that you do not store tablespaces with a 2K block size on 4K sector size disks, because performance degradation can result.

**Note:**

*Oracle Database Reference* for information on the `DB_nK_CACHE_SIZE` parameter and *Oracle Database Concepts* for information on multiple block sizes

***logging\_clause***

Specify the default logging attributes of all tables, indexes, materialized views, materialized view logs, and partitions within the tablespace. This clause is not valid for a temporary or undo tablespace.

If you omit this clause, then the default is `LOGGING`. The exception is creating a tablespace in a PDB. In this case, if you omit this clause, then the tablespace uses the logging attribute of the PDB. Refer to the [logging\\_clause](#) of CREATE PLUGGABLE DATABASE for more information.

The tablespace-level logging attribute can be overridden by logging specifications at the table, index, materialized view, materialized view log, and partition levels.

**Note:**

[logging\\_clause](#) for a full description of this clause

**FORCE LOGGING**

Use this clause to put the tablespace into `FORCE LOGGING` mode. Oracle Database will log all changes to all objects in the tablespace except changes to temporary segments, overriding any `NOLOGGING` setting for individual objects. The database must be open and in `READ WRITE` mode.

This setting does not exclude the `NOLOGGING` attribute. You can specify both `FORCE LOGGING` and `NOLOGGING`. In this case, `NOLOGGING` is the default logging mode for objects subsequently created in the tablespace, but the database ignores this default as long as the tablespace or the database is in `FORCE LOGGING` mode. If you subsequently take the tablespace out of `FORCE LOGGING` mode, then the `NOLOGGING` default is once again enforced.

**Note:**

`FORCE LOGGING` mode can have performance effects. Refer to *Oracle Database Administrator's Guide* for information on when to use this setting.

**Restriction on Forced Logging**

You cannot specify FORCE LOGGING for an undo or temporary tablespace.

#### ***tablespace\_encryption\_clause***

Use this clause to specify whether to create an encrypted or unencrypted tablespace. If you create an encrypted tablespace, then Transparent Data Encryption (TDE) is applied to all data files of the tablespace.

##### **ENCRYPT | DECRYPT**

Specify ENCRYPT to create an encrypted tablespace. Specify DECRYPT to create an unencrypted tablespace.

If you omit this clause, then the value of the ENCRYPT\_NEW\_TABLESPACES initialization parameter determines whether the tablespace is encrypted upon creation. Refer to *Oracle Database Reference* for more information on the ENCRYPT\_NEW\_TABLESPACES initialization parameter.

Before issuing this clause, you must already have loaded the TDE master key into database memory or established a connection to the HSM. For more information, see the [open\\_keystore](#) clause of ADMINISTER KEY MANAGEMENT or "SET ENCRYPTION WALLET Clause" of ALTER SYSTEM.

#### ***tablespace\_encryption\_spec***

Use USING 'encrypt\_algorithm' to specify the encryption algorithm.

Valid algorithms are AES256, AES192, AES128, and 3DES168.

Specify 'cipher\_mode' to determine how the TDE encrypted tablespace uses the tablespace key to encrypt data blocks. You can specify XTS (an XEX-based mode with ciphertext stealing mode) only with the encryption algorithms AES128 and AES256. For AES192 use CFB.

If you set the COMPATIBLE initialization parameter to 12.2 or higher, then the following algorithms are also valid: ARIA128, ARIA192, ARIA256, GOST256, and SEED128.

If you omit this clause, then the database uses AES128.

Starting with Oracle Database 23c, the Transparent Data Encryption (TDE) decryption libraries for the GOST and SEED algorithms are deprecated.

GOST 28147-89 has been deprecated by the Russian government, and SEED has been deprecated by the South Korean government. If you need South Korean government-approved TDE cryptography, then use ARIA instead. If you are using GOST 28147-89, then you must decrypt and encrypt with another supported TDE algorithm. The decryption algorithms for GOST 28147-89 and SEED are included in Oracle Database 23c, but are deprecated, and the GOST encryption algorithm is unsupported with Oracle Database 23c. If you are using GOST or SEED for TDE encryption, then Oracle recommends that you decrypt and encrypt with another algorithm before upgrading to Oracle Database 23c. However, with the exception of the HP Itanium platform, the GOST and SEED decryption libraries are available with Oracle Database 23c, so you can also decrypt after upgrading.

 See Also:

- "[Creating an Encrypted Tablespace: Example](#)"
- [Encryption Conversions for Tablespaces and Databases](#)

***default\_tablespace\_params***

The `DEFAULT` clause lets you specify default parameters for the tablespace.

***default\_table\_compression***

Use this clause to specify default compression of data for all tables created in the tablespace. This clause is not valid for a temporary tablespace. The subclauses of this clause have the same semantics as they have for the `table_compression` clause of the `CREATE TABLE` statement, with one exception: The `COMPRESS FOR OLTP` clause here is equivalent to the `ROW STORE COMPRESS ADVANCED` clause of `CREATE TABLE`. Refer to the [`table\_compression`](#) clauses of `CREATE TABLE` for the full semantics of these subclauses.

***default\_index\_compression***

Use this clause to specify default compression of data for all indexes created in the tablespace. This clause is not valid for a temporary tablespace. The subclauses of this clause have the same semantics as they have for the `advanced_index_compression` clause of the `CREATE INDEX` statement. Refer to the [`advanced\_index\_compression`](#) clause of `CREATE INDEX` for the full semantics of these subclauses.

***inmemory\_clause***

Use the `inmemory_clause` to specify the default In-Memory Column Store (IM column store) settings for all tables and materialized views created in the tablespace. This clause is not valid for a temporary tablespace.

- Specify `INMEMORY` to enable all tables and materialized views for the IM column store.

You can optionally use the `inmemory_attributes` clause to specify how the table or materialized view data is stored in the IM column store. The `inmemory_attributes` clause has the same semantics in `CREATE TABLE` and `CREATE TABLESPACE`. Refer to the [`inmemory\_attributes`](#) clause of `CREATE TABLE` for the full semantics of this clause.

- Specify `NO INMEMORY` to disable all tables and materialized views for the IM column store. This is the default.

***ilm\_clause***

Use the `ilm_clause` to specify default Automatic Data Optimization settings for all tables created in the tablespace. This clause is not valid for a temporary tablespace. Refer to the [`ilm\_clause`](#) of `CREATE TABLE` for the full semantics of this clause.

***storage\_clause***

Use the `storage_clause` to specify storage parameters for all objects created in the tablespace. This clause is not valid for a temporary tablespace or a locally managed tablespace. For a dictionary-managed tablespace, you can specify the following storage

parameters with this clause: ENCRYPT, INITIAL, NEXT, MINEXTENTS, MAXEXTENTS, MAXSIZE, and PCTINCREASE. Refer to [storage\\_clause](#) for more information.

 **Note:**

The ENCRYPT clause of the *storage\_clause* is supported for backward compatibility. However, beginning with Oracle Database 12c Release 2 (12.2), you can instead specify ENCRYPT in the *tablespace\_encryption\_clause*. Refer to [tablespace\\_encryption\\_clause](#) for more information.

 **See Also:**

["Creating Basic Tablespaces: Examples"](#)

## ONLINE | OFFLINE Clauses

Use these clauses to determine whether the tablespace is online or offline. This clause is not valid for a temporary tablespace.

### ONLINE

Specify ONLINE to make the tablespace available immediately after creation to users who have been granted access to the tablespace. This is the default.

### OFFLINE

Specify OFFLINE to make the tablespace unavailable immediately after creation.

The data dictionary view DBA\_TABLESPACES indicates whether each tablespace is online or offline.

## *extent\_management\_clause*

The *extent\_management\_clause* lets you specify how the extents of the tablespace will be managed.

 **Note:**

After you have specified extent management with this clause, you can change extent management only by migrating the tablespace.

- AUTOALLOCATE specifies that the tablespace is system managed. Users cannot specify an extent size. You cannot specify AUTOALLOCATE for a temporary tablespace.
- UNIFORM specifies that the tablespace is managed with uniform extents of SIZE bytes. The default SIZE is 1 megabyte. All extents of temporary tablespaces are of uniform size, so this keyword is optional for a temporary tablespace. However, you

must specify UNIFORM in order to specify SIZE. You cannot specify UNIFORM for an undo tablespace.

If you do not specify AUTOALLOCATE or UNIFORM, then the default is UNIFORM for temporary tablespaces and AUTOALLOCATE for all other types of tablespaces.

If you do not specify the `extent_management_clause`, then Oracle Database interprets the MINIMUM EXTENT clause and the DEFAULT storage\_clause to determine extent management.

#### Note:

The DICTIONARY keyword is deprecated. It is still supported for backward compatibility. However, Oracle recommends that you create locally managed tablespaces. Locally managed tablespaces are much more efficiently managed than dictionary-managed tablespaces. The creation of new dictionary-managed tablespaces is scheduled for desupport.

#### See Also:

*Oracle Database Concepts* for a discussion of locally managed tablespaces

### Restrictions on Extent Management

Extent management is subject to the following restrictions:

- A permanent locally managed tablespace can contain only permanent objects. If you need a locally managed tablespace to store temporary objects, for example, if you will assign it as a user's temporary tablespace, then use the `temporary_tablespace_clause`.
- If you specify this clause, then you cannot specify DEFAULT storage\_clause, MINIMUM EXTENT, or the `temporary_tablespace_clause`.

#### See Also:

*Oracle Database Administrator's Guide* for information on changing extent management by migrating tablespaces and "[Creating a Locally Managed Tablespace: Example](#)"

### *segment\_management\_clause*

The `segment_management_clause` is relevant only for permanent, locally managed tablespaces. It lets you specify whether Oracle Database should track the used and free space in the segments in the tablespace using free lists or bitmaps. This clause is not valid for a temporary tablespace.

#### AUTO

Specify AUTO if you want the database to manage the free space of segments in the tablespace using a bitmap. If you specify AUTO, then the database ignores any specification

for PCTUSED, FREELIST, and FREELIST GROUPS in subsequent storage specifications for objects in this tablespace. This setting is called **automatic segment-space management** and is the default.

#### MANUAL

Specify **MANUAL** if you want the database to manage the free space of segments in the tablespace using free lists. Oracle strongly recommends that you do not use this setting and that you create tablespaces with automatic segment-space management.

To determine the segment management of an existing tablespace, query the **SEGMENT\_SPACE\_MANAGEMENT** column of the **DBA\_TABLESPACES** or **USER\_TABLESPACES** data dictionary view.

#### Note:

If you specify **AUTO** segment management, then:

- If you set extent management to **LOCAL UNIFORM**, then you must ensure that each extent contains at least 5 database blocks.
- If you set extent management to **LOCAL AUTOALLOCATE**, and if the database block size is 16K or greater, then Oracle manages segment space by creating extents with a minimum size of 5 blocks rounded up to 64K.

#### Restrictions on Automatic Segment-Space Management

This clause is subject to the following restrictions:

- You can specify this clause only for a permanent, locally managed tablespace.
- You cannot specify this clause for the **SYSTEM** tablespace.

#### See Also:

- *Oracle Automatic Storage Management Administrator's Guide* for information on automatic segment-space management and when to use it
- *Oracle Database Reference* for information on the data dictionary views
- "["Specifying Segment Space Management for a Tablespace: Example"](#)

#### *flashback\_mode\_clause*

Use this clause in conjunction with the **ALTER DATABASE FLASHBACK** clause to specify whether the tablespace can participate in **FLASHBACK DATABASE** operations. This clause is useful if you have the database in **FLASHBACK mode** but you do not want Oracle Database to maintain Flashback log data for this tablespace.

This clause is not valid for temporary or undo tablespaces.

#### FLASHBACK ON

Specify FLASHBACK ON to put the tablespace in FLASHBACK mode. Oracle Database will save Flashback log data for this tablespace and the tablespace can participate in a FLASHBACK DATABASE operation. If you omit the *flashback\_mode\_clause*, then FLASHBACK ON is the default.

### FLASHBACK OFF

Specify FLASHBACK OFF to take the tablespace out of FLASHBACK mode. Oracle Database will not save any Flashback log data for this tablespace. You must take the data files in this tablespace offline or drop them prior to any subsequent FLASHBACK DATABASE operation. Alternatively, you can take the entire tablespace offline. In either case, the database does not drop existing Flashback logs.

#### Note:

The FLASHBACK mode of a tablespace is independent of the FLASHBACK mode of an individual table.

#### See Also:

- [Oracle Database Backup and Recovery User's Guide](#) for information on Oracle Flashback Database
- [ALTER DATABASE](#) and [FLASHBACK DATABASE](#) for information on setting the FLASHBACK mode of the entire database and reverting the database to an earlier version
- [FLASHBACK TABLE](#) and [flashback\\_query\\_clause](#)

### *lost\_write\_protection*

Specify the *lost\_write\_protection* clause to create a storage area for lost write records. This storage area or shadow tablespace must be created, before you can enable lost write protection on datafiles and databases.

You may create as many shadow tablespaces as you need, and name them as you would any other tablespace.

#### Example: Create a Shadow Tablespace in a Database

This example creates the shadow tablespace `sh_lwp1` for lost write protection:

```
CREATE BIGFILE TABLESPACE sh_lwp1 DATAFILE sh_lwp1.df SIZE 10M BLOCKSIZE 8K
  LOST WRITE PROTECTION;
```

To enable lost write protection on datafiles and databases, you must specify the *lost\_write\_protection* clause with the `ALTER TABLESPACE`, `ALTER DATABASE`, and `ALTER PLUGGABLE DATABASE` statements.

### *undo\_tablespace\_clause*

Specify `UNDO` to create an undo tablespace. When you run the database in automatic undo management mode, Oracle Database manages undo space using the undo tablespace

instead of rollback segments. This clause is useful if you are now running in automatic undo management mode but your database was not created in automatic undo management mode.

Oracle Database always assigns an undo tablespace when you start up the database in automatic undo management mode. If no undo tablespace has been assigned to this instance, then the database uses the SYSTEM rollback segment. You can avoid this by creating an undo tablespace, which the database will implicitly assign to the instance if no other undo tablespace is currently assigned.

The `DATAFILE` clause is described in "[DATAFILE | TEMPFILE Clause](#)".

#### ***extent\_management\_clause***

It is unnecessary to specify the `extent_management_clause` when creating an undo tablespace, because undo tablespaces must be locally managed tablespaces that use AUTOALLOCATE extent management. If you do specify this clause, then you must specify EXTENT MANAGEMENT LOCAL or EXTENT MANAGEMENT LOCAL AUTOALLOCATE, both of which are the same as omitting this clause. Refer to [extent\\_management\\_clause](#) for the full semantics of this clause.

#### ***tablespace\_retention\_clause***

This clause is valid only for undo tablespaces.

- RETENTION GUARANTEE specifies that Oracle Database should preserve unexpired undo data in all undo segments of `tablespace` even if doing so forces the failure of ongoing operations that need undo space in those segments. This setting is useful if you need to issue an Oracle Flashback Query or an Oracle Flashback Transaction Query to diagnose and correct a problem with the data.
- RETENTION NOGUARANTEE returns the undo behavior to normal. Space occupied by unexpired undo data in undo segments can be consumed if necessary by ongoing transactions. This is the default.

#### ***tablespace\_encryption\_clause***

This clause has the same semantics for undo tablespaces as for permanent tablespaces. Refer to [tablespace\\_encryption\\_clause](#) in the documentation on permanent tablespaces for full information.

### **Restrictions on Undo Tablespaces**

Undo tablespaces are subject to the following restrictions:

- You cannot create database objects in this tablespace. It is reserved for system-managed undo data.
- The only clauses you can specify for an undo tablespace are the `DATAFILE` clause, the `tablespace_retention_clause`, the `tablespace_encryption_clause`, and the `extent_management_clause` to specify local AUTOALLOCATE extent management. You cannot specify local UNIFORM extent management or dictionary extent management using the `extent_management_clause`. All undo tablespaces are created permanent, read/write, and in logging mode. Values for MINIMUM EXTENT and DEFAULT STORAGE are system generated.

 See Also:

- *Oracle Database Administrator's Guide* for information on automatic undo management and undo tablespaces and *Oracle Database Reference* for information on the `UNDO_MANAGEMENT` parameter
- [CREATE DATABASE](#) for information on creating an undo tablespace during database creation, and [ALTER TABLESPACE](#) and [DROP TABLESPACE](#)
- "[Creating an Undo Tablespace: Example](#)"

***temporary\_tablespace\_clause***

Use this clause to create a temporary tablespace, which is an allocation of space in the database that can contain transient data that persists only for the duration of a session. This transient data cannot be recovered after process or instance failure.

The transient data can be user-generated schema objects such as temporary tables or system-generated data such as temp space used by hash joins and sort operations. When a temporary tablespace, or a tablespace group of which this tablespace is a member, is assigned to a particular user, then Oracle Database uses the tablespace for sorting operations in transactions initiated by that user.

You can create two types of temporary tablespaces:

- You can create a shared temporary tablespace by specifying the `TEMPORARY TABLESPACE` clause. A shared temporary tablespace stores temp files on shared disk, so that the temporary space is accessible to all database instances. Shared temporary tablespaces were available in prior releases of Oracle Database and were called "temporary tablespaces." Elsewhere in this guide, the term "temporary tablespace" refers to a shared temporary tablespace unless specified otherwise.
- Starting with Oracle Database 12c Release 2 (12.2), you can create a local temporary tablespace by specifying the `LOCAL TEMPORARY TABLESPACE` clause. Local temporary tablespaces are useful in an Oracle Clusterware environment. They store a separate, nonshared temp files for each database instance, which can improve I/O performance. A local temporary tablespace must be a `BIGFILE` tablespace.
  - Specify `FOR ALL` to instruct the database to create separate, nonshared temp files for all HUB and LEAF nodes.
  - Specify `FOR LEAF` to instruct the database to create separate nonshared temp files for only LEAF nodes.

**TEMPFILE**

The `TEMPFILE` clause is described in "[DATAFILE | TEMPFILE Clause](#)".

***tablespace\_group\_clause***

This clause is relevant only for temporary tablespaces. Use this clause to determine whether `tablespace` is a member of a tablespace group. A tablespace group lets you assign multiple temporary tablespaces to a single user and increases the addressability of temporary tablespaces.

- Specify a group name to indicate that `tablespace` is a member of this tablespace group. The group name cannot be the same as `tablespace` or any other existing tablespace. If

the tablespace group already exists, then Oracle Database adds the new tablespace to that group. If the tablespace group does not exist, then the database creates the group and adds the new tablespace to that group.

- Specify an empty string (' ') to indicate that `tablespace` is not a member of any tablespace group.

### Restriction on Tablespace Groups

Tablespace groups support only shared temporary tablespaces. You cannot add a local temporary tablespace to a tablespace group.

#### ***extent\_management\_clause***

The `extent_management_clause` is described in [extent\\_management\\_clause](#).

#### ***tablespace\_encryption\_clause***

This clause has the same semantics for temporary tablespaces as for permanent tablespaces. Refer to [tablespace\\_encryption\\_clause](#) in the documentation on permanent tablespaces for full information.

#### See Also:

- [ALTER TABLESPACE](#) and "[Adding a Temporary Tablespace to a Tablespace Group: Example](#)" for information on adding a tablespace to a tablespace group
- [CREATE USER](#) for information on assigning a temporary tablespace to a user
- [Oracle Database Administrator's Guide](#) for more information on tablespace groups

### Restrictions on Temporary Tablespaces

The data stored in temporary tablespaces persists only for the duration of a session. Therefore, only a subset of the `CREATE TABLESPACE` clauses are relevant for temporary tablespaces. The only clauses you can specify for a temporary tablespace are the `TEMPFILE clause`, the `tablespace_group_clause`, the `extent_management_clause`, and the `tablespace_encryption_clause`.

### Examples

These examples assume that your database is using 8K blocks.

#### **Creating a Bigfile Tablespace: Example**

The following example creates a bigfile tablespace `bigtbs_01` with a data file `bigtbs_f1.dbf` of 20 MB:

```
CREATE BIGFILE TABLESPACE bigtbs_01
  DATAFILE 'bigtbs_f1.dbf'
  SIZE 20M AUTOEXTEND ON;
```

#### **Creating an Undo Tablespace: Example**

The following example creates a 10 MB undo tablespace `undots1`:

```
CREATE UNDO TABLESPACE undots1
  DATAFILE 'undotbs_1a.dbf'
  SIZE 10M AUTOEXTEND ON
  RETENTION GUARANTEE;
```

### Creating a Temporary Tablespace: Example

This statement shows how the temporary tablespace that serves as the default temporary tablespace for database users in the sample database was created:

```
CREATE TEMPORARY TABLESPACE temp_demo
  TEMPFILE 'temp01.dbf' SIZE 5M AUTOEXTEND ON;
```

Assuming that the default database block size is 2K, and that each bit in the map represents one extent, then each bit maps 2,500 blocks.

The following example sets the default location for data file creation and then creates a tablespace with an Oracle-managed temp file in the default location. The temp file is 100 M and is autoextensible with unlimited maximum size. These are the default values for Oracle Managed Files:

```
ALTER SYSTEM SET DB_CREATE_FILE_DEST = '$ORACLE_HOME/rdbms/dbs';
CREATE TEMPORARY TABLESPACE tbs_05;
```

### Adding a Temporary Tablespace to a Tablespace Group: Example

The following statement creates the tbs\_temp\_02 temporary tablespace as a member of the tbs\_grp\_01 tablespace group. If the tablespace group does not already exist, then Oracle Database creates it during execution of this statement:

```
CREATE TEMPORARY TABLESPACE tbs_temp_02
  TEMPFILE 'temp02.dbf' SIZE 5M AUTOEXTEND ON
  TABLESPACE GROUP tbs_grp_01;
```

### Creating Basic Tablespaces: Examples

This statement creates a tablespace named tbs\_01 with one data file:

```
CREATE TABLESPACE tbs_01
  DATAFILE 'tbs_f2.dbf' SIZE 40M
  ONLINE;
```

This statement creates tablespace tbs\_03 with one data file and allocates every extent as a multiple of 500K:

```
CREATE TABLESPACE tbs_03
  DATAFILE 'tbs_f03.dbf' SIZE 20M
  LOGGING;
```

### Enabling Autoextend for a Tablespace: Example

This statement creates a tablespace named tbs\_02 with one data file. When more space is required, 500 kilobyte extents will be added up to a maximum size of 100 megabytes:

```
CREATE TABLESPACE tbs_02
  DATAFILE 'diskb:tbs_f5.dbf' SIZE 500K REUSE
  AUTOEXTEND ON NEXT 500K MAXSIZE 100M;
```

### Creating a Locally Managed Tablespace: Example

The following statement assumes that the database block size is 2K.

```
CREATE TABLESPACE tbs_04 DATAFILE 'file_1.dbf' SIZE 10M
EXTENT MANAGEMENT LOCAL UNIFORM SIZE 128K;
```

This statement creates a locally managed tablespace in which every extent is 128K and each bit in the bit map describes 64 blocks.

The following statement creates a locally managed tablespace with uniform extents and shows an example of a table stored in that tablespace:

```
CREATE TABLESPACE lmt1 DATAFILE 'lmt_file2.dbf' SIZE 100m REUSE
EXTENT MANAGEMENT LOCAL UNIFORM SIZE 1M;
```

```
CREATE TABLE lmt_table1 (col1 NUMBER, col2 VARCHAR2(20))
TABLESPACE lmt1 STORAGE (INITIAL 2m);
```

The initial segment size of the table is 2M.

The following example creates a locally managed tablespace without uniform extents:

```
CREATE TABLESPACE lmt2 DATAFILE 'lmt_file3.dbf' SIZE 100m REUSE
EXTENT MANAGEMENT LOCAL;
```

```
CREATE TABLE lmt_table2 (col1 NUMBER, col2 VARCHAR2(20))
TABLESPACE lmt2 STORAGE (INITIAL 2m MAXSIZE 100m);
```

The initial segment size of the table is 2M. Oracle Database determines the size of each extent and the total number of extents allocated to satisfy the initial segment size. The segment's maximum size is limited to 100M.

### **Creating an Encrypted Tablespace: Example**

In the following example, the first statement enables encryption for the database by opening the wallet. The second statement creates an encrypted tablespace.

```
ALTER SYSTEM SET ENCRYPTION WALLET OPEN IDENTIFIED BY "wallet_password";
```

```
CREATE TABLESPACE encrypt_ts
DATAFILE '$ORACLE_HOME/dbs/encrypt_df.dbf' SIZE 1M
ENCRYPTION USING 'AES256' ENCRYPT;
```

The following example creates a tablespace encts2 using the encryption algorithm AES256 and cipher mode XTS:

```
CREATE TABLESPACE encts2 DATAFILE 'encts2.f' SIZE 1G ENCRYPTION USING AES256
MODE 'XTS' ENCRYPT;
```

### **Specifying Segment Space Management for a Tablespace: Example**

The following example creates a tablespace with automatic segment-space management:

```
CREATE TABLESPACE auto_seg_ts DATAFILE 'file_2.dbf' SIZE 1M
EXTENT MANAGEMENT LOCAL
SEGMENT SPACE MANAGEMENT AUTO;
```

### **Creating Oracle Managed Files: Examples**

The following example sets the default location for data file creation and creates a tablespace with a data file in the default location. The data file is 100M and is autoextensible with an unlimited maximum size:

```
ALTER SYSTEM SET DB_CREATE_FILE_DEST = '$ORACLE_HOME/rdbms/dbs';  
  
CREATE TABLESPACE omf_ts1;
```

The following example creates a tablespace with an Oracle-managed data file of 100M that is not autoextensible:

```
CREATE TABLESPACE omf_ts2 DATAFILE AUTOEXTEND OFF;
```

## CREATE TABLESPACE SET

### Note:

This SQL statement is valid only if you are using Oracle Sharding. For more information on Oracle Sharding, refer to *Oracle Database Administrator's Guide*.

### Purpose

Use the CREATE TABLESPACE SET statement to create a tablespace set. A tablespace set can be used in a sharded database as a logical storage unit for one or more sharded tables and indexes.

A tablespace set consists of multiple tablespaces distributed across shards in a shardspace. The database automatically creates the tablespaces in a tablespace set. The number of tablespaces is determined automatically and is equal to the number of chunks in the corresponding shardspace.

All tablespaces in a tablespace set are permanent bigfile tablespaces; a tablespace set does not contain SYSTEM, undo, or temporary tablespaces. The database automatically creates one data file for each tablespace. All tablespaces in a tablespace set share the same attributes. You can modify attributes for all tablespaces in a tablespace set with the ALTER TABLESPACE SET statement.

### See Also:

[ALTER TABLESPACE SET](#) and [DROP TABLESPACE SET](#)

### Prerequisites

You must be connected to a shard catalog database as an SDB user.

You must have the CREATE TABLESPACE system privilege.

## Syntax

*create\_tablespace\_set ::=*

*permanent\_tablespace\_attrs ::=*

(*file\_specification ::=*, See the following clauses of CREATE TABLESPACE:  
*logging\_clause ::=*, *tablespace\_encryption\_clause ::=*, *default\_tablespace\_params ::=*,  
*extent\_management\_clause ::=*, *segment\_management\_clause ::=*,  
*flashback\_mode\_clause ::=*)

## Semantics

### *tablespace\_set*

Specify the name of the tablespace set to be created. The name must satisfy the requirements listed in [Database Object Naming Rules](#).

## IN SHARDSPACE

Specify this clause if you are using composite sharding. For *shardspace\_name*, specify the name of the shardspace in which the tablespace set is to be created.

Omit this clause if you are using system-managed sharding. In this case, the tablespace set is created in the default shardspace for the sharded database.

## USING TEMPLATE

The **USING TEMPLATE** clause allows you to specify attributes for the tablespaces in the tablespace set.

The **DATAFILE** and **permanent\_tablespace\_attrs** clauses have the same semantics here as for the **CREATE TABLESPACE** statement, with the following exceptions:

- For the **DATAFILE file\_specification** clause, you can specify only the **SIZE** clause and the **autoextend\_clause**.
- You cannot specify the **MINIMUM EXTENT size\_clause**.
- For the **segment\_management\_clause**, you can specify only **SEGMENT SPACE MANAGEMENT AUTO**. The **MANUAL** setting is not supported.

### See Also:

[file\\_specification](#) and [permanent\\_tablespace\\_attrs](#) in the documentation on **CREATE TABLESPACE** for the full semantics of these clauses

## Examples

### Creating a Tablespace Set: Example

The following statement creates tablespace set `ts1`:

```
CREATE TABLESPACE SET ts1
    IN SHARDSPACE sgr1
    USING TEMPLATE
    ( DATAFILE SIZE 100m
        EXTENT MANAGEMENT LOCAL
        SEGMENT SPACE MANAGEMENT AUTO
    );
```

# CREATE TRIGGER

## Purpose

Triggers are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the **CREATE TRIGGER** statement to create a **database trigger**, which is:

- A stored PL/SQL block associated with a table, a schema, or the database or

- An anonymous PL/SQL block or a call to a procedure implemented in PL/SQL or Java

Oracle Database automatically executes a trigger when specified conditions occur.

### See Also:

[ALTER TRIGGER](#) and [DROP TRIGGER](#)

### Prerequisites

To create a trigger in your own schema on a table in your own schema or on your own schema (`SCHEMA`), you must have the `CREATE TRIGGER` system privilege.

To create a trigger in any schema on a table in any schema, or on another user's schema (`schema.SCHEMA`), you must have the schema level `CREATE ANY TRIGGER` privilege both in the schema where the trigger is created and in the schema where table resides, or you must have the `CREATE ANY TRIGGER` system privilege.

In addition to the preceding privileges, to create a trigger on `DATABASE`, you must have the `ADMINISTER DATABASE TRIGGER` system privilege.

To create a trigger on a pluggable database (PDB), the current container must be that PDB and you must have the `ADMINISTER DATABASE TRIGGER` system privilege. For information about PDBs, see *Oracle Database Administrator's Guide*.

In addition to the preceding privileges, to create a crossedition trigger, you must be enabled for editions. For information about enabling editions for a user, see *Oracle Database Development Guide*.

If the trigger issues SQL statements or calls procedures or functions, then the owner of the trigger must have the privileges necessary to perform these operations. These privileges must be granted directly to the owner rather than acquired through roles.

### Syntax

Triggers are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

**`create_trigger::=`**

(`plsql_trigger_source`: See *Oracle Database PL/SQL Language Reference*.)

## Semantics

### OR REPLACE

Specify `OR REPLACE` to re-create the trigger if it already exists. Use this clause to change the definition of an existing trigger without first dropping it.

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the trigger does not exist, a new trigger is created at the end of the statement.
- If the trigger exists, this is the trigger you have at the end of the statement. A new one is not created because the older one is detected.

You can have *one* of `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error:  
`ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

### [ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the trigger is an editioned or noneditioned object if editioning is enabled for the schema object type `TRIGGER` in *schema*. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

### Restriction on NONEDITIONABLE

You cannot specify `NONEDITIONABLE` for a crossedition trigger.

### `plsql_trigger_source`

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the `plsql_trigger_source`.

# CREATE TYPE

## Purpose

Object types are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `CREATE TYPE` statement to create the specification of an **object type**, a **SQLJ object type**, a named varying array (**varray**), a **nested table type**, or an **incomplete object type**. You create object types with the `CREATE TYPE` and the `CREATE TYPE BODY` statements. The `CREATE TYPE` statement specifies the name of the object type, its attributes, methods, and other properties. The `CREATE TYPE BODY` statement contains the code for the methods that implement the type.

 **Note:**

- If you create an object type for which the type specification declares only attributes but no methods, then you need not specify a type body.
- If you create a SQLJ object type, then you cannot specify a type body. The implementation of the type is specified as a Java class.

An **incomplete type** is a type created by a forward type definition. It is called "incomplete" because it has a name but no attributes or methods. It can be referenced by other types, and so can be used to define types that refer to each other. However, you must fully specify the type before you can use it to create a table or an object column or a column of a nested table type.

 **See Also:**

- [CREATE TYPE BODY](#) for information on creating the member methods of a type
- *Oracle Database Object-Relational Developer's Guide* for more information about objects, incomplete types, varrays, and nested tables

### Prerequisites

To create a type in your own schema, you must have the `CREATE TYPE` system privilege. To create a type in another user's schema, you must have the `CREATE ANY TYPE` system privilege. You can acquire these privileges explicitly or be granted them through a role.

To create a subtype, you must have the `UNDER ANY TYPE` system privilege or the `UNDER` object privilege on the supertype.

The owner of the type must be explicitly granted the `EXECUTE` object privilege in order to access all other types referenced within the definition of the type, or the type owner must be granted the `EXECUTE ANY TYPE` system privilege. The owner cannot obtain these privileges through roles.

If the type owner intends to grant other users access to the type, then the owner must be granted the `EXECUTE` object privilege on the referenced types with the `GRANT OPTION` or the `EXECUTE ANY TYPE` system privilege with the `ADMIN OPTION`. Otherwise, the type owner has insufficient privileges to grant access on the type to other users.

### User-Defined Datatypes Declared as Non-Persistable Datatypes

You can specify a user-defined datatype as non-persistent when creating the datatype. Instances of non-persistent types cannot persist on disk. Persistent data types include the following:

- ANSI-supported data types, for example `NUMERIC`, `DECIMAL`, `REAL`.
- Oracle built-in data types, for example `NUMBER`, `VARCHAR2`, `TIMESTAMP`.
- Oracle-supplied data types, for example `ANYDATA`, `XML Type`, `ORDImage`.

## Rules For SQL User-Defined Data Types

- A persistable type cannot have attributes or elements of non-persistent types.
- A non-persistent type can have attributes or elements of both persistable and non-persistent types.
- A sub-type must inherit the persistence property from its super type.
- A `REF` type is persistable and can hold references only to objects of persistable types.
- You cannot persist instances of non-persistent types on disk. If you create a table with a type that has been declared as non-persistent, the `CREATE TABLE` statement will fail. The following operations will likewise fail:
  - Create or alter a relational table with columns of non-persistent types.
  - Create an object table with columns of non-persistent types.
  - Store instances of non-persistent types in an `ANYDATA` instance which is persisted on disk.

You can specify unique PL/SQL attributes in the `CREATE TYPE` statement in the PL/SQL context only.

## Syntax

Types are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

**`create_type ::=`**

(`plsql_type_source`: See *Oracle Database PL/SQL Language Reference*.)

## Semantics

### OR REPLACE

Specify `OR REPLACE` to re-create the type if it already exists. Use this clause to change the definition of an existing type without first dropping it.

Users previously granted privileges on the re-created object type can use and reference the object type without being granted privileges again.

If any function-based indexes depend on the type, then Oracle Database marks the indexes `DISABLED`.

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the type does not exist, a new type is created at the end of the statement.

- If the type exists, this is the type you have at the end of the statement. A new one is not created because the older one is detected.

You can have `one of OR REPLACE or IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error: ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

#### [ EDITIONABLE | NONEDITIONABLE ]

Use these clauses to specify whether the type is an editioned or noneditioned object if editioning is enabled for the schema object type `TYPE` in `schema`. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

#### `plsql_type_source`

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the `plsql_type_source`.

## CREATE TYPE BODY

### Purpose

Type bodies are defined using PL/SQL. Therefore, this section provides some general information but refers to *Oracle Database PL/SQL Language Reference* for details of syntax and semantics.

Use the `CREATE TYPE BODY` to define or implement the member methods defined in the object type specification. You create object types with the `CREATE TYPE` and the `CREATE TYPE BODY` statements. The `CREATE TYPE` statement specifies the name of the object type, its attributes, methods, and other properties. The `CREATE TYPE BODY` statement contains the code for the methods that implement the type.

For each method specified in an object type specification for which you did not specify the `call_spec`, you must specify a corresponding method body in the object type body.

#### Note:

If you create a SQLJ object type, then specify it as a Java class.

#### See Also:

- [CREATE TYPE](#) for information on creating a type specification
- [ALTER TYPE](#) for information on modifying a type specification

## Prerequisites

Every member declaration in the `CREATE TYPE` specification for object types must have a corresponding construct in the `CREATE TYPE` or `CREATE TYPE BODY` statement.

To create or replace a type body in your own schema, you must have the `CREATE TYPE` or the `CREATE ANY TYPE` system privilege. To create an object type in another user's schema, you must have the `CREATE ANY TYPE` system privilege. To replace an object type in another user's schema, you must have the `DROP ANY TYPE` system privilege.

## Syntax

Type bodies are defined using PL/SQL. Therefore, the syntax diagram in this book shows only the SQL keywords. Refer to *Oracle Database PL/SQL Language Reference* for the PL/SQL syntax, semantics, and examples.

`create_type_body ::=`

(`plsql_type_body_source`: See *Oracle Database PL/SQL Language Reference*.)

## Semantics

### OR REPLACE

Specify `OR REPLACE` to re-create the type body if it already exists. Use this clause to change the definition of an existing type body without first dropping it.

Users previously granted privileges on the re-created object type body can use and reference the object type body without being granted privileges again.

You can use this clause to add new member subprogram definitions to specifications added with the `ALTER TYPE ... REPLACE` statement.

### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the type body does not exist, a new type body is created at the end of the statement.
- If the type body exists, this is the type body you have at the end of the statement. A new one is not created because the older one is detected.

You can have **one of** `OR REPLACE` or `IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error:  
 ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.

Using IF EXISTS with CREATE results in ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.

#### [ EDITIONABLE | NONEDITIONABLE ]

If you do not specify this clause, then the type body inherits EDITIONABLE or NONEDITIONABLE from the type specification. If you do specify this clause, then it must match that of the type specification.

#### *plsql\_type\_body\_source*

See *Oracle Database PL/SQL Language Reference* for the syntax and semantics of the *plsql\_type\_body\_source*.

## CREATE USER

### Purpose

Use the CREATE USER statement to create and configure a database **user**, which is an account through which you can log in to the database, and to establish the means by which Oracle Database permits access by the user.

You can issue this statement in an Oracle Automatic Storage Management (Oracle ASM) cluster to add a user and password combination to the password file that is local to the Oracle ASM instance of the current node. Each node's Oracle ASM instance can use this statement to update its own password file. The password file itself must have been created by the ORAPWD utility.

You can enable a user to connect to the database through a proxy application or application server. For syntax and discussion, refer to [ALTER USER](#) .

### Prerequisites

You must have the CREATE USER system privilege. When you create a user with the CREATE USER statement, the user's privilege domain is empty. To log on to Oracle Database, a user must have the CREATE SESSION system privilege. Therefore, after creating a user, you should grant the user at least the CREATE SESSION system privilege. Refer to [GRANT](#) for more information.

Only a user authenticated AS SYSASM can issue this command to modify the Oracle ASM instance password file.

To specify the CONTAINER clause, you must be connected to a multitenant container database (CDB). To specify CONTAINER = ALL, the current container must be the root. To specify CONTAINER = CURRENT, the current container must be a pluggable database (PDB).

## Syntax

*create\_user ::=*

(*size\_clause ::=*)

### Semantics

#### IF NOT EXISTS

Specifying `IF NOT EXISTS` has the following effects:

- If the user does not exist, a new user is created at the end of the statement.
- If the user exists, this is the user you have at the end of the statement. A new one is not created because the older one is detected.

Using `IF EXISTS` with `CREATE` results in ORA-11543: Incorrect `IF NOT EXISTS` clause for `CREATE` statement.

#### *user*

Specify the name of the user to be created. This name can contain only characters from your database character set and must follow the rules described in the section "[Database Object Naming Rules](#)". Oracle recommends that the user name contain at least one single-byte character regardless of whether the database character set also contains multibyte characters.

In a non-CDB, a user name cannot begin with `C##` or `c##`.

#### Note:

A multitenant container database is the only supported architecture in Oracle Database 21c and later releases. While the documentation is being revised, legacy terminology may persist. In most cases, "database" and "non-CDB" refer to a CDB or PDB, depending on context. In some contexts, such as upgrades, "non-CDB" refers to a non-CDB from a previous release.

In a CDB, the requirements for a user name are as follows:

- The name of a **common user** must begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. By default, the prefix is `C##`.
- The name of a **local user** must not begin with characters that are a case-insensitive match to the prefix specified by the `COMMON_USER_PREFIX` initialization parameter. Regardless of the value of `COMMON_USER_PREFIX`, the name of a local user can never begin with `C##` or `c##`.

 **Note:**

If the value of `COMMON_USER_PREFIX` is an empty string, then there are no requirements for common or local user names with one exception: the name of a local user can never begin with `C##` or `c##`. Oracle recommends against using an empty string value because it might result in conflicts between the names of local and common users when a PDB is plugged into a different CDB, or when opening a PDB that was closed when a common user was created.

 **Note:**

Oracle recommends that user names and passwords be encoded in ASCII or EBCDIC characters only, depending on your platform.

 **See Also:**

["Creating a Database User: Example"](#)

### IDENTIFIED Clause

The `IDENTIFIED` clause lets you indicate how Oracle Database authenticates the user.

#### **BY password**

The `BY password` clause lets you creates a **local user** and indicates that the user must specify `password` to log on to the database. Passwords are case sensitive and their maximum length is 1024 bytes. Any subsequent `CONNECT` string used to connect this user to the database must specify the password using the same case (upper, lower, or mixed) that is used in this `CREATE USER` statement or a subsequent `ALTER USER` statement. Passwords can contain any single-byte, multibyte, or special characters, or any combination of these, from your database character set, with the exception of the double quotation mark ("") and the return character . If a password starts with a non-alphabetic character, or contains a character other than an alphanumeric character, the underscore (\_), dollar sign (\$), or pound sign (#), then it must be enclosed in double quotation marks. Otherwise, enclosing a password in double quotation marks is optional.

 **See Also:**

[Oracle Database Security Guide](#) for more information about case-sensitive passwords, password complexity, and other password guidelines

Passwords must follow the rules described in the section "[Database Object Naming Rules](#)", unless you are using one of the three Oracle Database password complexity verification routines. These routines requires a more complex combination of characters than the normal

naming rules permit. You implement these routines with the UTLPWDMG.SQL script, which is further described in *Oracle Database Security Guide*.

 **Note:**

Oracle recommends that user names and passwords be encoded in ASCII or EBCDIC characters only, depending on your platform.

 **See Also:**

*Oracle Database Security Guide* for a detailed discussion of password management and protection

### [HTTP] DIGEST Clause

This clause lets you `ENABLE` or `DISABLE` HTTP Digest Access Authentication for the user. The default is `DISABLE`.

The `HTTP` keyword is optional and is provided for semantic clarity.

#### Restriction on the [HTTP] DIGEST Clause

You cannot specify this clause for external or global users.

### EXTERNALLY Clause

Specify `EXTERNALLY` to create an **external user**. Such a user must be authenticated by an external service, such as an operating system or a third-party service. In this case, Oracle Database relies on authentication by the operating system or third-party service to ensure that a specific external user has access to a specific database user.

#### AS 'certificate\_DN'

This clause is required for and used for SSL-authenticated external users only. The `certificate_DN` is the distinguished name in the user's PKI certificate in the user's wallet. The maximum length of `certificate_DN` is 1024 characters.

#### AS 'kerberos\_principal\_name'

This clause is required for and used for Kerberos-authenticated external users only. The maximum length of `kerberos_principal_name` is 1024 characters.

 **Note:**

Oracle strongly recommends that you do not use `IDENTIFIED EXTERNALLY` with operating systems that have inherently weak login security.

### Restriction on Creating External Users

Oracle ASM does not support the creation of external users.

 See Also:

- *Oracle Database Enterprise User Security Administrator's Guide* for more information on externally identified users
- "[Creating External Database Users: Examples](#)"

### GLOBALLY Clause

The `GLOBALLY` clause lets you create a **global user**. Such a user must be authorized by the enterprise directory service (Oracle Internet Directory).

The `directory_DN` string can take one of two forms:

- The X.509 name at the enterprise directory service that identifies this user. It should be of the form `CN=username,other_attributes`, where `other_attributes` is the rest of the user's distinguished name (DN) in the directory. This form uses the LDAP Data Interchange Format (LDIF) and creates a **private global schema**.
- A null string (' ') indicating that the enterprise directory service will map authenticated global users to this database schema with the appropriate roles. This form is the same as specifying the `GLOBALLY` keyword alone and creates a **shared global schema**.

The maximum length of `directory_DN` is 1024 characters.

You can control the ability of an application server to connect as the specified user and to activate that user's roles using the `ALTER USER` statement.

You can exclusively map an Oracle Database schema to a Microsoft Azure AD user using `GLOBALLY AS AZURE_USER`. You must log in to the Oracle Autonomous Database instance as a user who has been granted the `CREATE USER` or `ALTER USER` system privilege.

#### Example: Map Oracle Database Schema to a Microsoft Azure AD User

The example creates a new database schema user named `peter_fitch` and maps this user to an existing Azure AD user named `peter.fitch@example.com`:

```
CREATE USER peter_fitch IDENTIFIED GLOBALLY AS 'AZURE_USER=peter.fitch@example.com';
```

#### Example: Map a Shared Oracle Database Schema to an App Role

The example creates a new database global user account (schema) named `dba_azure` and maps it to an existing Azure AD application role named `AZURE_DB`:

```
CREATE USER dba_azure IDENTIFIED GLOBALLY AS 'AZURE_ROLE=AZURE_DB';
```

#### Restriction on Creating Global Users

Oracle ASM does not support the creation of global users.

 **See Also:**

- *Oracle Database Security Guide* for more information on global users
- *Authenticating and Authorizing Microsoft Azure Active Directory Users for Oracle Autonomous Databases*
- [ALTER USER](#)
- ["Creating a Global Database User: Example"](#)

**NO AUTHENTICATION Clause**

Use the `NO AUTHENTICATION` clause to create a schema that does not have a password and cannot be logged into. This is intended for schema only accounts and reduces maintenance by removing default passwords and any requirement to rotate the password.

**DEFAULT COLLATION Clause**

This clause lets you specify the default collation for the schema owned by the user. The default collation is assigned to tables, views, and materialized views that are subsequently created in the schema.

For `collation_name`, specify a valid named collation or pseudo-collation.

If you omit this clause, then the default collation for the schema owned by the user is set to the `USING_NLS_COMP` pseudo-collation.

You can override this clause and assign a different default collation to a particular table, materialized view, or view by specifying the `DEFAULT COLLATION` clause of the `CREATE` or `ALTER` statement for the table, materialized view, or view. You can also override the default collations of all schemas for the duration of a database session by setting the default collation for the session. See the [DEFAULT\\_COLLATION](#) clause of `ALTER SESSION` for more details.

You can specify the `DEFAULT COLLATION` clause only if the `COMPATIBLE` initialization parameter is set to 12.2 or greater, and the `MAX_STRING_SIZE` initialization parameter is set to EXTENDED.

**DEFAULT TABLESPACE Clause**

Specify the default tablespace for objects that are created in the user's schema. If you omit this clause, then the user's objects are stored in the database default tablespace. If no default tablespace has been specified for the database, then the user's objects are stored in the `SYSTEM` tablespace.

**Restriction on Default Tablespaces**

You cannot specify a locally managed temporary tablespace, including an undo tablespace, or a dictionary-managed temporary tablespace, as a user's default tablespace.

 **See Also:**

- [CREATE TABLESPACE](#) for more information on tablespaces in general and undo tablespaces in particular
- *Oracle Database Security Guide* for more information on assigning default tablespaces to users

**[LOCAL] TEMPORARY TABLESPACE Clause**

Specify the tablespace or tablespace group for the user's temporary segments. If you omit this clause, then the user's temporary segments are stored in the database default temporary tablespace or, if none has been specified, in the `SYSTEM` tablespace.

- Specify `tablespace` to indicate the user's temporary tablespace. Specify `TEMPORARY TABLESPACE` to indicate a shared temporary tablespace. Specify `LOCAL TEMPORARY TABLESPACE` to indicate a local temporary tablespace. If you are connected to a CDB, then you can specify `CDB$DEFAULT` to use the CDB-wide default temporary tablespace.
- Specify `tablespace_group_name` to indicate that the user can save temporary segments in any tablespace in the tablespace group specified by `tablespace_group_name`. Local temporary tablespaces cannot be part of a tablespace group.

**Restrictions on Temporary Tablespace**

This clause is subject to the following restrictions:

- The tablespace must be a temporary tablespace and must have a standard block size.
- The tablespace cannot be an undo tablespace or a tablespace with automatic segment-space management.

 **See Also:**

- *Oracle Database Administrator's Guide* for information about tablespace groups and *Oracle Database Security Guide* for information on assigning temporary tablespaces to users
- [CREATE TABLESPACE](#) for more information on undo tablespaces and segment management
- "[Assigning a Tablespace Group: Example](#)"

**QUOTA Clause**

Use the `QUOTA` clause to specify the maximum amount of space the user can allocate in the tablespace.

A `CREATE USER` statement can have multiple `QUOTA` clauses for multiple tablespaces.

`UNLIMITED` lets the user allocate space in the tablespace without bound.

The maximum amount of space that you can specify is 2 terabytes (TB). If you need more space, then specify `UNLIMITED`.

### Restriction on the QUOTA Clause

You cannot specify this clause for a temporary tablespace.

#### See Also:

[size\\_clause](#) for information on that clause and *Oracle Database Security Guide* for more information on assigning tablespace quotas

### PROFILE Clause

Specify the profile you want to assign to the user. The profile limits the amount of database resources the user can use. If you omit this clause, then Oracle Database assigns the `DEFAULT` profile to the user.

You can use the `CREATE USER` statement to create a new user, and associate the user with a profile that has the `PASSWORD_ROLLOVER_TIME` configured.

You must first set the password rollover period using `CREATE PROFILE` or `ALTER PROFILE`.

In the example `u1` is the user, with password `p1`. `prof1` is the profile with `PASSWORD_ROLLOVER_TIME` set.

```
CREATE USER u1 IDENTIFIED BY p1 PROFILE prof1 ;
```

#### Note:

Oracle recommends that you use the Database Resource Manager to establish database resource limits rather than SQL profiles. The Database Resource Manager offers a more flexible means of managing and tracking resource use. For more information on the Database Resource Manager, refer to *Oracle Database Administrator's Guide*.

#### See Also:

- [GRANT](#) and [CREATE PROFILE](#)
- Configuring Authentication

### PASSWORD EXPIRE Clause

Specify `PASSWORD EXPIRE` if you want the user's password to expire. This setting forces the user or the DBA to change the password before the user can log in to the database.

## ACCOUNT Clause

Specify ACCOUNT LOCK to lock the user's account and disable access. Specify ACCOUNT UNLOCK to unlock the user's account and enable access to the account. The default is ACCOUNT UNLOCK.

## ENABLE EDITIONS

This clause is not reversible. Specify ENABLE EDITIONS to allow the user to create multiple versions of editionable objects in this schema using editions. Editionable objects in schemas that are not editions-enabled cannot be editioned.

Note the following before enabling editions with ALTER USER:

- Enabling editions is not a live operation.
- When a database is upgraded from Release 11.2 to Release 12.1, users who were enabled for editions in the pre-upgrade database are enabled for editions in the post-upgrade database and the default schema object types are editionable in their schemas. The default schema object types are displayed by the static data dictionary view DBA\_EDITIONED\_TYPES . Users who were not enabled for editions in the pre-upgrade database are not enabled for editions in the post-upgrade database and no schema object types are editionable in their schemas.
- To see which users already have editions enabled, see the EDITIONS\_ENABLED column of the static data dictionary view DBA\_USERS or USER\_USERS .

## Restriction on Enabling Editions

The FOR clause is ignored when used with ENABLE EDITIONS. This only applies to the CREATE USER statement, not the ALTER USER statement.

You cannot enable editions for any schemas supplied by Oracle.

### See Also:

- *Enabling Editions for a User*
- *Oracle Database Reference* for more information about the V\$EDITIONABLE\_TYPES dynamic performance view

## CONTAINER Clause

The CONTAINER clause applies when you are connected to a CDB. However, it is not necessary to specify the CONTAINER clause because its default values are the only allowed values.

- To create a common user, you must be connected to the root. You can optionally specify CONTAINER = ALL, which is the default when you are connected to the root.
- To create a local user, you must be connected to a PDB. You can optionally specify CONTAINER = CURRENT, which is the default when you are connected to a PDB.

While creating a common user, any default tablespace, temporary tablespace, or profile specified using the following clauses must exist in all the containers belonging to the CDB:

- DEFAULT TABLESPACE
- TEMPORARY TABLESPACE
- QUOTA
- PROFILE

If these objects do not exist in all the containers, the `CREATE USER` statement fails.

### READ ONLY | READ WRITE

Use this clause to set `READ ONLY` access to a local PDB user.

With `read-only` access, the local PDB user is not permitted to execute any write operations on the PDB they connect to. The session operates as if the database is open in `read-only` mode.

Specify `READ WRITE` to set `READ WRITE` access to a local user.

You must have the `CREATE USER` privilege to execute this statement.

You can view the state of a local user in the `*_USERS` view.

### Examples

All of the following examples use the `example` tablespace, which exists in the seed database and is accessible to the sample schemas.

#### Creating a Database User: Example

If you create a new user with `PASSWORD EXPIRE`, then the user's password must be changed before the user attempts to log in to the database. You can create the user `sidney` by issuing the following statement:

```
CREATE USER sidney
    IDENTIFIED BY out_standing1
    DEFAULT TABLESPACE example
    QUOTA 10M ON example
    TEMPORARY TABLESPACE temp
    QUOTA 5M ON system
    PROFILE app_user
    PASSWORD EXPIRE;
```

The user `sidney` has the following characteristics:

- The password `out_standing1`
- Default tablespace `example`, with a quota of 10 megabytes
- Temporary tablespace `temp`
- Access to the tablespace `SYSTEM`, with a quota of 5 megabytes
- Limits on database resources defined by the profile `app_user` (which was created in "[Creating a Profile: Example](#)")
- An expired password, which must be changed before `sidney` can log in to the database

#### Creating External Database Users: Examples

The following example creates an external user, who must be identified by an external source before accessing the database:

```
CREATE USER app_user1
  IDENTIFIED EXTERNALLY
  DEFAULT TABLESPACE example
  QUOTA 5M ON example
  PROFILE app_user;
```

The user `app_user1` has the following additional characteristics:

- Default tablespace `example`
- Default temporary tablespace `example`
- 5M of space on the tablespace `example` and unlimited quota on the temporary tablespace of the database
- Limits on database resources defined by the `app_user` profile

To create another user accessible only by an operating system account, prefix the user name with the value of the initialization parameter `OS_AUTHENT_PREFIX`. For example, if this value is `"ops$"`, then you can create the externally identified user `external_user` with the following statement:

```
CREATE USER ops$external_user
  IDENTIFIED EXTERNALLY
  DEFAULT TABLESPACE example
  QUOTA 5M ON example
  PROFILE app_user;
```

### Creating a Global Database User: Example

The following example creates a global user. When you create a global user, you can specify the X.509 name that identifies this user at the enterprise directory server:

```
CREATE USER global_user
  IDENTIFIED GLOBALLY AS 'CN=analyst, OU=division1, O=oracle, C=US'
  DEFAULT TABLESPACE example
  QUOTA 5M ON example;
```

### Creating a Common User in a CDB

The following example creates a common user called `c##comm_user` in a CDB. Before you run this `CREATE USER` statement, ensure that the tablespaces `example` and `temp_tbs` exist in all of the containers in the CDB.

```
CREATE USER c##comm_user
  IDENTIFIED BY comm_pwd
  DEFAULT TABLESPACE example
  QUOTA 20M ON example
  TEMPORARY TABLESPACE temp_tbs;
```

The user `comm_user` has the following additional characteristics:

- The password `comm_pwd`
- Default tablespace `example`, with a quota of 20 megabytes
- Temporary tablespace `temp_tbs`

# CREATE VIEW

## Purpose

Use the `CREATE VIEW` statement to define a **view**, which is a logical table based on one or more tables or views. A view contains no data itself. The tables upon which a view is based are called **base tables**.

You can also create an **object view** or a relational view that supports LOBs, object types, `REF` data types, nested table, or varray types on top of the existing view mechanism. An object view is a view of a user-defined type, where each row contains objects, each object with a unique object identifier.

You can also create `XMLType` views, which are similar to object views but display data from XMLSchema-based tables of `XMLType`.

### See Also:

- *Oracle Database Concepts*, *Oracle Database Development Guide*, and *Oracle Database Administrator's Guide* for information on various types of views and their uses
- *Oracle XML DB Developer's Guide* for information on `XMLType` views
- [ALTER VIEW](#) and [DROP VIEW](#) for information on modifying a view and removing a view from the database

## Prerequisites

To create a view in your own schema, you must have the `CREATE VIEW` system privilege. To create a view in another user's schema, you must have the `CREATE ANY VIEW` system privilege.

To create a subview, you must have the `UNDER ANY VIEW` system privilege or the `UNDER` object privilege on the superview.

The owner of the schema containing the view must have the privileges necessary to either select (`READ` or `SELECT` privilege), insert, update, or delete rows from all the tables or views on which the view is based. The owner must be granted these privileges directly, rather than through a role.

To use the basic constructor method of an object type when creating an object view, one of the following must be true:

- The object type must belong to the same schema as the view to be created.
- You must have the `EXECUTE ANY TYPE` system privileges.
- You must have the `EXECUTE` object privilege on that object type.

## See Also:

**SELECT** , **INSERT** , **UPDATE** , and **DELETE** for information on the privileges required by the owner of a view on the base tables or views of the view being created

## Syntax

**create view::=**

(*inline\_constraint*::= and *out\_of\_line\_constraint*::=, *object\_view\_clause*::=,  
*XMLType\_view\_clause*::=, *subquery*::=—part of SELECT, *subquery\_restriction\_clause*::=,  
*annotations\_clause*)

***object\_view\_clause ::=***

(*inline\_constraint ::=* and *out\_of\_line\_constraint ::=*)

***XMLType\_view\_clause ::=***

***XMLSchema\_spec ::=***

***annotations\_clause ::=***

For the full syntax and semantics of the *annotations\_clause* see [annotations\\_clause](#).

***subquery\_restriction\_clause ::=***

## Semantics

### OR REPLACE

Specify `OR REPLACE` to re-create the view if it already exists. You can use this clause to change the definition of an existing view without dropping, re-creating, and regranting object privileges previously granted on it.

`INSTEAD OF` triggers defined on a conventional view are dropped when the view is re-created. DML triggers defined on an editioning view are retained when an editioning view is re-created. However, such triggers can be rendered permanently invalid if the editioning view has changed so that it can no longer be compiled—for example if an editioning view column referenced in the trigger definition has been dropped.

If any materialized views are dependent on `view`, then those materialized views will be marked `UNUSABLE` and will require a full refresh to restore them to a usable state. Invalid materialized views cannot be used by query rewrite and cannot be refreshed until they are recompiled.

You cannot replace a conventional view with an editioning view or an editioning view with a conventional view. See *Oracle Database Development Guide* for more information on editioning views.

#### See Also:

- [ALTER MATERIALIZED VIEW](#) for information on refreshing invalid materialized views
- *Oracle Database Concepts* for information on materialized views in general
- [CREATE TRIGGER](#) for more information about the `INSTEAD OF` clause

## FORCE

Specify `FORCE` if you want to create the view regardless of whether the base tables of the view or the referenced object types exist or the owner of the schema containing the view has privileges on them. These conditions must be true before any `SELECT`, `INSERT`, `UPDATE`, or `DELETE` statements can be issued against the view.

If the view definition contains any constraints, `CREATE VIEW ... FORCE` fails if the base table does not exist or the referenced object type does not exist. `CREATE VIEW ... FORCE` also fails if the view definition names a constraint that does not exist.

## NO FORCE

Specify `NOFORCE` if you want to create the view only if the base tables exist and the owner of the schema containing the view has privileges on them. This is the default.

## EDITIONING

Use this clause to create an **editioning view**. An editioning view is a single-table view that selects all rows from the base table and displays a subset of the base table columns. You can use an editioning view to isolate an application from DDL changes to the base table during administrative operations such as upgrades. You can obtain information about the relationship of existing editioning view to their base tables by querying the `USER_`, `ALL_`, and `DBA_EDITIONING_VIEW` data dictionary views.

The owner of an editioning view must be editions-enabled. Refer to [ENABLE EDITIONS](#) for more information.

### Notes on Editioning Views

Editioning views differ from conventional views in several important ways:

- Editioning views are intended only to select and provide aliases for a subset of columns in a table. Therefore, the syntax for creating an editioning view is more limited than the syntax for creating a conventional view. Any violation of the restrictions that follow causes the creation of the view to fail, even if you specify `FORCE`.
- You can create DML triggers on editioning views. In this case, the database considers the editioning view to be the base object of the trigger. Such triggers fire when a DML operation targets the editioning view itself. They do not fire if the DML operation targets the base table.
- You cannot create `INSTEAD OF` triggers on editioning views.

### Restrictions on Editioning Views

Editioning views are subject to the following restrictions:

- Within any edition, you can create only one editioning view for any single table.
- You cannot specify the `object_view_clause`, `XMLType_view_clause`, or `BEQUEATH` clause.
- You cannot define a constraint `WITH CHECK OPTION` on an editioning view.
- In the select list of the defining subquery, you can specify only simple references to the columns of the base table, and you can specify each column of the base table only once in the select list. The asterisk wildcard symbol `*` and `t_alias.*` are supported to designate all columns of a base table.
- The `FROM` clause of the defining subquery of the view can reference only a single existing database table. Joins are not permitted. The base table must be in the same schema as the view being created. You cannot use a synonym to identify the table, but you can specify a table alias.
- The following clauses of the defining subquery are not valid for editioning views: `subquery_factoring_clause`, `DISTINCT` or `UNIQUE`, `where_clause`, `hierarchical_query_clause`, `group_by_clause`, `HAVING condition`, `model_clause`, or the set operators (`UNION`, `INTERSECT`, or `MINUS`)

 See Also:

- *Oracle Database Development Guide* for detailed information about editioning views
- [CREATE EDITION](#) for information about editions, including an example of an editioning view

**EDITIONABLE | NONEDITIONABLE**

Use these clauses to specify whether the view becomes an editioned or noneditioned object if editioning is enabled for the schema object type `VIEW` in `schema`. The default is `EDITIONABLE`. For information about editioned and noneditioned objects, see *Oracle Database Development Guide*.

**IF NOT EXISTS**

Specifying `IF NOT EXISTS` has the following effects:

- If the view does not exist, a new view is created at the end of the statement.
- If the view exists, this is the view you have at the end of the statement. A new one is not created because the older one is detected.

You can have `one of OR REPLACE or IF NOT EXISTS` in a statement at a time. Using both `OR REPLACE` with `IF NOT EXISTS` in the very same statement results in the following error:  
`ORA-11541: REPLACE and IF NOT EXISTS cannot coexist in the same DDL statement.`

Using `IF EXISTS` with `CREATE` results in `ORA-11543: Incorrect IF NOT EXISTS clause for CREATE statement.`

***schema***

Specify the schema to contain the view. If you omit `schema`, then Oracle Database creates the view in your own schema.

***view***

Specify the name of the view or the object view. The name must satisfy the requirements listed in "[Database Object Naming Rules](#)".

**Restriction on Views**

If a view has `INSTEAD OF` triggers, then any views created on it must have `INSTEAD OF` triggers, even if the views are inherently updatable.

 See Also:

- ["Creating a View: Example"](#)

## SHARING

This clause applies only when creating a view in an application root. This type of view is called an application common object and its data can be shared with the application PDBs that belong to the application root. To determine how the view data is shared, specify one of the following sharing attributes:

- METADATA - A metadata link shares the view's metadata, but its data is unique to each container. This type of view is referred to as a **metadata-linked application common object**.
- DATA - A data link shares the view, and its data is the same for all containers in the application container. Its data is stored only in the application root. This type of view is referred to as a **data-linked application common object**.
- EXTENDED DATA - An extended data link shares the view, and its data in the application root is the same for all containers in the application container. However, each application PDB in the application container can store data that is unique to the application PDB. For this type of view, data is stored in the application root and, optionally, in each application PDB. This type of view is referred to as an **extended data-linked application common object**.
- NONE - The view is not shared.

If you omit this clause, then the database uses the value of the `DEFAULT_SHARING` initialization parameter to determine the sharing attribute of the view. If the `DEFAULT_SHARING` initialization parameter does not have a value, then the default is METADATA.

When creating a conventional view, you can specify METADATA, DATA, EXTENDED DATA, or NONE.

When creating an object view or an XMLTYPE view, you can specify only METADATA or NONE.

You cannot change the sharing attribute of a view after it is created.

### See Also:

- *Oracle Database Reference* for more information on the `DEFAULT_SHARING` initialization parameter
- *Oracle Database Administrator's Guide* for complete information on creating application common objects

## alias

Specify names for the expressions selected by the defining query of the view. The number of aliases must match the number of expressions selected by the view. Aliases must follow the rules for naming Oracle Database schema objects. Aliases must be unique within the view.

If you omit the aliases, then the database derives them from the columns or column aliases in the query. For this reason, you must use aliases if the query contains

expressions rather than only column names. Also, you must specify aliases if the view definition includes constraints and/or column annotations.

### Restriction on View Aliases

You cannot specify an alias when creating an object view.

#### See Also:

["Syntax for Schema Objects and Parts in SQL Statements"](#)

### VISIBLE | INVISIBLE

Use this clause to specify whether a view column is VISIBLE or INVISIBLE. By default, view columns are VISIBLE regardless of their visibility in the base tables, unless you specify INVISIBLE. This applies to conventional views and editioning views. For complete information on these clauses, refer to "[VISIBLE | INVISIBLE](#)" in the documentation on CREATE TABLE.

#### *inline\_constraint* and *out\_of\_line\_constraint*

You can specify constraints on views and object views. You define the constraint at the view level using the *out\_of\_line\_constraint* clause. You define the constraint as part of column or attribute specification using the *inline\_constraint* clause after the appropriate alias.

Oracle Database does not enforce view constraints. For a full discussion of view constraints, including restrictions, refer to "[View Constraints](#)".

#### See Also:

["Creating a View with Constraints: Example"](#)

### *object\_view\_clause*

The *object\_view\_clause* lets you define a view on an object type.

#### See Also:

["Creating an Object View: Example"](#)

### OF *type\_name* Clause

Use this clause to explicitly create an **object view** of type *type\_name*. The columns of an object view correspond to the top-level attributes of type *type\_name*. Each row will contain an object instance and each instance will be associated with an object identifier as specified in the WITH OBJECT IDENTIFIER clause. If you omit *schema*, then the database creates the object view in your own schema.

Object tables, as well as XMLType tables, object views, and XMLType views, do not have any column names specified for them. Therefore, Oracle Database defines a system-generated

pseudocolumn `OBJECT_ID`. You can use this column name in queries and to create object views with the `WITH OBJECT IDENTIFIER` clause.

### WITH OBJECT IDENTIFIER Clause

Use the `WITH OBJECT IDENTIFIER` clause to specify a top-level (root) object view. This clause lets you specify the attributes of the object type that will be used as a key to identify each row in the object view. In most cases these attributes correspond to the primary key columns of the base table. You must ensure that the attribute list is unique and identifies exactly one row in the view. The `WITH OBJECT IDENTIFIER` and `WITH OBJECT ID` clauses can be used interchangeably and are provided for semantic clarity.

### Restrictions on Object Views

Object views are subject to the following restrictions:

- If you try to dereference or pin a primary key `REF` that resolves to more than one instance in the object view, then the database returns an error.
- You cannot specify this clause if you are creating a subview, because subviews inherit object identifiers from superviews.

If the object view is defined on an object table or an object view, then you can omit this clause or specify `DEFAULT`.

### DEFAULT

Specify `DEFAULT` if you want the database to use the intrinsic object identifier of the underlying object table or object view to uniquely identify each row.

#### **attribute**

For `attribute`, specify an attribute of the object type from which the database should create the object identifier for the object view.

### UNDER Clause

Use the `UNDER` clause to specify a subview based on an object superview.

### Restrictions on Subviews

Subviews are subject to the following restrictions:

- You must create a subview in the same schema as the superview.
- The object type `type_name` must be the immediate subtype of `superview`.
- You can create only one subview of a particular type under the same superview.

#### See Also:

- [CREATE TYPE](#) for information about creating objects
- [Oracle Database Reference](#) for information on data dictionary views

### ***XMLType\_view\_clause***

Use this clause to create an `XMLType` view, which displays data from an `XMLSchema`-based table of type `XMLType`. The `XMLSchema_spec` indicates the `XMLSchema` to be

used to map the XML data to its object-relational equivalents. The XMLSchema must already have been created before you can create an XMLType view.

The WITH OBJECT IDENTIFIER and WITH OBJECT ID clauses can be used interchangeably and are provided for semantic clarity.

Object tables, as well as XMLType tables, object views, and XMLType views, do not have any column names specified for them. Therefore, Oracle Database defines a system-generated pseudocolumn OBJECT\_ID. You can use this column name in queries and to create object views with the WITH OBJECT IDENTIFIER clause.

#### See Also:

- *Oracle XML DB Developer's Guide* for information on XMLType views and XMLSchemas
- "[Creating an XMLType View: Example](#)" and "[Creating a View on an XMLType Table: Example](#)"

#### ***annotations\_clause***

For the full semantics of the annotations clause see [annotations\\_clause](#).

#### **DEFAULT COLLATION**

Use this clause to specify the default collation for the view. The default collation is used as the derived collation for all the character literals included in the defining query of the view. The default collation is not used by the view columns; the collations for the view columns are derived from the view's defining subquery. The CREATE VIEW statement fails with an error if any of its character columns is based on an expression in the defining subquery that has no derived collation.

For *collation\_name*, specify a valid named collation or pseudo-collation.

If you omit this clause, then the default collation for the view is set to the effective schema default collation of the schema containing the view. Refer to the **DEFAULT\_COLLATION** clause of ALTER SESSION for more information on the effective schema default collation.

You can specify the DEFAULT COLLATION clause only if the COMPATIBLE initialization parameter is set to 12.2 or greater, and the MAX\_STRING\_SIZE initialization parameter is set to EXTENDED.

To change the default collation for a view, you must recreate the view.

#### **Restriction on the Default Collation for Views**

If the defining query of the view contains the WITH *plsql\_declarations* clause, then the default collation of the view must be USING\_NLS\_COMP.

#### **BEQUEATH**

Use the BEQUEATH clause to specify whether functions referenced in the view are executed using the view invoker's rights or the view definer's rights.

#### **CURRENT\_USER**

If you specify `BEQUEATH CURRENT_USER`, then functions referenced by the view are executed using the view invoker's rights as long as one of the following conditions is met:

- The view owner has the `INHERIT PRIVILEGES` object privilege on the invoking user.
- The view owner has the `INHERIT ANY PRIVILEGES` system privilege.

If a query of the view invokes an identity- or privilege-sensitive SQL function, or an invoker's rights PL/SQL or Java function, then the current schema, current user, and currently enabled roles within the operation's execution are inherited from the querying user's environment, rather than from the owner of the view.

This clause does not turn the view itself into an invoker's rights object. Name resolution within the view is still handled using the view owner's schema, and privilege checking for the view is done using the view owner's privileges.

#### DEFINER

If you specify `BEQUEATH DEFINER`, then functions referenced by the view are executed using the view definer's rights. If a query on the view invokes an identity- or privilege-sensitive SQL function, or an invoker's rights PL/SQL or Java function, then the current schema, current user, and currently enabled roles within the operation's execution are inherited from the owner of the view.

Name resolution within the view is handled using the view owner's schema, and privilege checking for the view is done using the view owner's privileges.

This is the default.

#### Restriction on the BEQUEATH Clause

You cannot specify this clause with the `EDITIONING` clause.

#### See Also:

*Oracle Database Security Guide* for more information on controlling invoker's rights and definer's rights in views

#### AS subquery

Specify a subquery that identifies columns and rows of the table(s) that the view is based on. The select list of the subquery can contain up to 1000 expressions.

If you create views that refer to remote tables and views, then the database links you specify must have been created using the `CONNECT TO` clause of the `CREATE DATABASE LINK` statement, and you must qualify them with a schema name in the view subquery.

If you create a view with the `flashback_query_clause` in the defining query, then the database does not interpret the `AS OF` expression at create time but rather each time a user subsequently queries the view.

 **See Also:**

"[Creating a Join View: Example](#)" and *Oracle Database Development Guide* for more information on Oracle Flashback Query

### Restrictions on the Defining Query of a View

The view query is subject to the following restrictions:

- The subquery cannot select the CURRVAL or NEXTVAL pseudocolumns.
- If the subquery selects the ROWID, ROWNUM, or LEVEL pseudocolumns, then those columns must have aliases in the view subquery.
- If the subquery uses an asterisk (\*) to select all columns of a table, and you later add new columns to the table, then the view will not contain those columns until you re-create the view by issuing a CREATE OR REPLACE VIEW statement.
- For object views, the number of elements in the subquery select list must be the same as the number of top-level attributes for the object type. The data type of each of the selecting elements must be the same as the corresponding top-level attribute.
- You cannot specify the SAMPLE clause.

The preceding restrictions apply to materialized views as well.

### Notes on Updatable Views

The following notes apply to updatable views:

An updatable view is one you can use to insert, update, or delete base table rows. You can create a view to be inherently updatable, or you can create an INSTEAD OF trigger on any view to make it updatable.

To learn whether and in what ways the columns of an inherently updatable view can be modified, query the `USER_UPDATABLE_COLUMNS` data dictionary view. The information displayed by this view is meaningful only for inherently updatable views. For a view to be inherently updatable, the following conditions must be met:

- Each column in the view must map to a column of a single table. For example, if a view column maps to the output of a TABLE clause (an unnested collection), then the view is not inherently updatable.
- The view must not contain any of the following constructs:
  - A set operator
  - A DISTINCT operator
  - An aggregate or analytic function
  - A GROUP BY, ORDER BY, MODEL, CONNECT BY, or START WITH clause
  - A collection expression in a SELECT list
  - A subquery in a SELECT list
  - A subquery designated WITH READ ONLY
  - Joins, with some exceptions, as documented in *Oracle Database Administrator's Guide*

- In addition, if an inherently updatable view contains pseudocolumns or expressions, then you cannot update base table rows with an `UPDATE` statement that refers to any of these pseudocolumns or expressions.
- If you want a join view to be updatable, then all of the following conditions must be true:
  - The DML statement must affect only one table underlying the join.
  - For an `INSERT` statement, the view must not be created `WITH CHECK OPTION`, and all columns into which values are inserted must come from a **key-preserved table**. A key-preserved table is one for which every primary key or unique key value in the base table is also unique in the join view.
  - For an `UPDATE` statement, the view must not be created `WITH CHECK OPTION`, and update must be deterministic (updates each row only once).
  - For a `DELETE` statement, if the join results in more than one key-preserved table, then Oracle Database deletes from the first table named in the `FROM` clause, whether or not the view was created `WITH CHECK OPTION`.

#### See Also:

- *Oracle Database Administrator's Guide* for more information on updatable views
- "[Creating an Updatable View: Example](#)", "[Creating a Join View: Example](#)" for an example of updatable join views and key-preserved tables, and *Oracle Database PL/SQL Language Reference* for an example of an `INSTEAD OF` trigger on a view that is not inherently updatable

#### subquery\_restriction\_clause

Use the `subquery_restriction_clause` to restrict the defining query of the view in one of the following ways:

##### **WITH READ ONLY**

Specify `WITH READ ONLY` to indicate that the table or view cannot be updated.

##### **WITH CHECK OPTION**

Specify `WITH CHECK OPTION` to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the `FROM` clause but not in subquery in the `WHERE` clause.

##### **CONSTRAINT constraint**

Specify the name of the `READ ONLY` or `CHECK OPTION` constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form `SYS_Cn`, where *n* is an integer that makes the constraint name unique within the database.

 **Note:**

For tables, WITH CHECK OPTION guarantees that inserts and updates result in tables that the defining table subquery can select. For views, WITH CHECK OPTION cannot make this guarantee if:

- There is a subquery within the defining query of this view or any view on which this view is based or
- INSERT, UPDATE, or DELETE operations are performed using INSTEAD OF triggers.

**Restriction on the *subquery\_restriction\_clause***

You cannot specify this clause if you specify an ORDER BY clause.

 **See Also:**

["Creating a Read-Only View: Example"](#)

**CONTAINER\_MAP**

Specify the CONTAINER\_MAP clause to enable the view to be queried using a container map.

**CONTAINERS\_DEFAULT**

Specify the CONTAINERS\_DEFAULT clause to enable the view for the CONTAINERS clause.

**Examples****Creating a View: Example**

The following statement creates a view of the sample table employees named emp\_view. The view shows the employees in department 20 and their annual salary:

```
CREATE VIEW emp_view AS
  SELECT last_name, salary*12 annual_salary
    FROM employees
   WHERE department_id = 20;
```

The view declaration need not define a name for the column based on the expression salary\*12, because the subquery uses a column alias (annual\_salary) for this expression.

**Creating an Editioning View: Example**

The following statement creates an editioning view of the orders table:

```
CREATE EDITIONING VIEW ed_orders_view (o_id, o_date, o_status)
  AS SELECT order_id, order_date, order_status FROM orders
  WITH READ ONLY;
```

You can use this view to isolate an application from DDL changes to the orders table during an administrative operation such as an upgrade. You can create a DML trigger on this view, so that the trigger fires when a DML operation targets the view itself, but does not fire if the DML operation targets the orders table.

### Creating a View with Constraints: Example

The following statement creates a restricted view of the sample table `hr.employees` and defines a unique constraint on the `email` view column and a primary key constraint for the view on the `emp_id` view column:

```
CREATE VIEW emp_sal (emp_id, last_name,
    email UNIQUE RELY DISABLE NOVALIDATE,
    CONSTRAINT id_pk PRIMARY KEY (emp_id) RELY DISABLE NOVALIDATE)
AS SELECT employee_id, last_name, email FROM employees;
```

### Creating an Updatable View: Example

The following statement creates an updatable view named `clerk` of all clerks in the `employees` table. Only the employees' IDs, last names, department numbers, and jobs are visible in this view, and these columns can be updated only in rows where the employee is a kind of clerk:

```
CREATE VIEW clerk AS
    SELECT employee_id, last_name, department_id, job_id
    FROM employees
    WHERE job_id = 'PU_CLERK'
        or job_id = 'SH_CLERK'
        or job_id = 'ST_CLERK';
```

This view lets you change the `job_id` of a purchasing clerk to purchasing manager (`PU_MAN`):

```
UPDATE clerk SET job_id = 'PU_MAN' WHERE employee_id = 118;
```

The next example creates the same view WITH CHECK OPTION. You cannot subsequently insert a new row into `clerk` if the new employee is not a clerk. You can update an employee's `job_id` from one type of clerk to another type of clerk, but the update in the preceding statement would fail, because the view cannot access employees with non-clerk `job_id`.

```
CREATE VIEW clerk AS
    SELECT employee_id, last_name, department_id, job_id
    FROM employees
    WHERE job_id = 'PU_CLERK'
        or job_id = 'SH_CLERK'
        or job_id = 'ST_CLERK'
    WITH CHECK OPTION;
```

### Creating a Join View: Example

A join view is one whose view subquery contains a join. If at least one column in the join has a unique index, then it may be possible to modify one base table in a join view. You can query `USER_UPDATABLE_COLUMNS` to see whether the columns in a join view are updatable. For example:

```
CREATE VIEW locations_view AS
    SELECT d.department_id, d.department_name, l.location_id, l.city
    FROM departments d, locations l
    WHERE d.location_id = l.location_id;

SELECT column_name, updatable
    FROM user_updatable_columns
    WHERE table_name = 'LOCATIONS_VIEW'
    ORDER BY column_name, updatable;
```

| COLUMN_NAME     | UPD |
|-----------------|-----|
| DEPARTMENT_ID   | YES |
| DEPARTMENT_NAME | YES |
| LOCATION_ID     | NO  |
| CITY            | NO  |

In the preceding example, the primary key index on the `location_id` column of the `locations` table is not unique in the `locations_view` view. Therefore, `locations` is not a key-preserved table and columns from that base table are not updatable.

```
INSERT INTO locations_view VALUES
    (999, 'Entertainment', 87, 'Roma');
INSERT INTO locations_view VALUES
*
ERROR at line 1:
ORA-01776: cannot modify more than one base table through a join view
```

You can insert, update, or delete a row from the `departments` base table, because all the columns in the view mapping to the `departments` table are marked as updatable and because the primary key of `departments` is retained in the view.

```
INSERT INTO locations_view (department_id, department_name)
VALUES (999, 'Entertainment');

1 row created.
```

#### Note:

For you to insert into the table using the view, the view must contain all `NOT NULL` columns of all tables in the join, unless you have specified `DEFAULT` values for the `NOT NULL` columns.

#### See Also:

*Oracle Database Administrator's Guide* for more information on updating join views

### Creating a Read-Only View: Example

The following statement creates a read-only view named `customer_ro` of the `oe.customers` table. Only the customers' last names, language, and credit limit are visible in this view:

```
CREATE VIEW customer_ro (name, language, credit)
AS SELECT cust_last_name, nls_language, credit_limit
FROM customers
WITH READ ONLY;
```

### Creating an Object View: Example

The following example shows the creation of the type `inventory_typ` in the `oc` schema, and the `oc_inventories` view that is based on that type:

```

CREATE TYPE inventory_typ
OID '82A4AF6A4CD4656DE034080020E0EE3D'
AS OBJECT
( product_id      NUMBER(6)
, warehouse       warehouse_typ
, quantity_on_hand NUMBER(8)
) ;
/
CREATE OR REPLACE VIEW oc_inventories OF inventory_typ
WITH OBJECT OID (product_id)
AS SELECT i.product_id,
          warehouse_typ(w.warehouse_id, w.warehouse_name, w.location_id),
          i.quantity_on_hand
     FROM inventories i, warehouses w
    WHERE i.warehouse_id=w.warehouse_id;

```

### **Creating a View on an XMLType Table: Example**

The following example builds a regular view on the XMLType table xwarehouses, which was created in "[Examples](#)":

```

CREATE VIEW warehouse_view AS
  SELECT VALUE(p) AS warehouse_xml
    FROM xwarehouses p;

```

You select from such a view as follows:

```

SELECT e.warehouse_xml.getclobval()
  FROM warehouse_view e
 WHERE EXISTSNODE(warehouse_xml, '//Docks') =1;

```

### **Creating an XMLType View: Example**

In some cases you may have an object-relational table upon which you would like to build an XMLType view. The following example creates an object-relational table resembling the XMLType column warehouse\_spec in the sample table oe.warehouses, and then creates an XMLType view of that table:

```

CREATE TABLE warehouse_table
(
  WarehouseID      NUMBER,
  Area             NUMBER,
  Docks            NUMBER,
  DockType         VARCHAR2(100),
  WaterAccess      VARCHAR2(10),
  RailAccess        VARCHAR2(10),
  Parking           VARCHAR2(20),
  VClearance        NUMBER
);

INSERT INTO warehouse_table
  VALUES(5, 103000,3,'Side Load','false','true','Lot',15);

CREATE VIEW warehouse_view OF XMLTYPE
  XMLSCHEMA "http://www.example.com/xwarehouses.xsd"
  ELEMENT "Warehouse"
  WITH OBJECT ID
  (extract(OBJECT_VALUE, '/Warehouse/Area/text()').getnumbererval())
AS SELECT XMLELEMENT("Warehouse",
                      XMLFOREST(WarehouseID as "Building",
                                 area as "Area",

```

```
docks as "Docks",
docktype as "DockType",
wateraccess as "WaterAccess",
railaccess as "RailAccess",
parking as "Parking",
VClearance as "VClearance"))
FROM warehouse_table;
```

You query this view as follows:

```
SELECT VALUE(e) FROM warehouse_view e;
```

## DELETE

### Purpose

Use the `DELETE` statement to remove rows from:

- An unpartitioned or partitioned table
- The unpartitioned or partitioned base table of a view
- The unpartitioned or partitioned container table of a writable materialized view
- The unpartitioned or partitioned master table of an updatable materialized view

### Prerequisites

For you to delete rows from a table, the table must be in your own schema or you must have the `DELETE` object privilege on the table.

For you to delete rows from an updatable materialized view, the materialized view must be in your own schema or you must have the `DELETE` object privilege on the materialized view.

For you to delete rows from the base table of a view, the owner of the schema containing the view must have the `DELETE` object privilege on the base table. Also, if the view is in a schema other than your own, then you must have the `DELETE` object privilege on the view.

The `DELETE ANY TABLE` system privilege also allows you to delete rows from any table or table partition or from the base table of any view.

To delete rows from an object on a remote database, you must also have the `READ` or `SELECT` object privilege on the object.

If the `SQL92_SECURITY` initialization parameter is set to `TRUE` and the `DELETE` operation references table columns, such as the columns in a `where_clause`, then you must also have the `SELECT` object privilege on the object from which you want to delete rows.

You cannot delete rows from a table if a function-based index on the table has become invalid. You must first validate the function-based index.

## Syntax

**delete ::=**

(*DML\_table\_expression\_clause ::=, where\_clause ::=, returning\_clause ::=, error\_logging\_clause ::=, from\_using\_clause ::=*)

**DML\_table\_expression\_clause ::=**

(*partition\_extension\_clause ::=, subquery ::=, subquery\_restriction\_clause ::=, table\_collection\_expression ::=*)

**partition\_extension\_clause ::=**

**subquery\_restriction\_clause ::=**

*table\_collection\_expression*::=

### ***from\_using\_clause ::=***

*where\_clause*::=

*returning\_clause*::=

*error\_logging\_clause*::=

## Semantics

### *hint*

Specify a comment that passes instructions to the optimizer on choosing an execution plan for the statement.

 **See Also:**

"[Hints](#)" for the syntax and description of hints

### *from\_clause*

Use the `FROM` clause to specify the database objects from which you are deleting rows.

The `ONLY` syntax is relevant only for views. Use the `ONLY` clause if the view in the `FROM` clause belongs to a view hierarchy and you do not want to delete rows from any of its subviews.

### *DML\_table\_expression\_clause*

Use this clause to specify the objects from which data is being deleted.

### *schema*

Specify the schema containing the table or view. If you omit `schema`, then Oracle Database assumes the table or view is in your own schema.

### *table | view | materialized view | subquery*

Specify the name of a table, view, materialized view, or the column or columns resulting from a subquery, from which the rows are to be deleted.

When you delete rows from an updatable view, Oracle Database deletes rows from the base table.

You cannot delete rows from a read-only materialized view. If you delete rows from a writable materialized view, then the database removes the rows from the underlying container table. However, the deletions are overwritten at the next refresh operation. If you delete rows from an updatable materialized view that is part of a materialized view group, then the database also removes the corresponding rows from the master table.

If `table` or the base table of `view` or the master table of `materialized_view` contains one or more domain index columns, then this statement executes the appropriate `indextype` delete routine.

 **See Also:**

[Oracle Database Data Cartridge Developer's Guide](#) for more information on these routines

Issuing a `DELETE` statement against a table fires any `DELETE` triggers defined on the table. All table or index space released by the deleted rows is retained by the table and index.

#### ***partition\_extension\_clause***

Specify the name or partition key value of the partition or subpartition targeted for deletes within the object.

You need not specify the partition name when deleting values from a partitioned object. However, in some cases, specifying the partition name is more efficient than a complicated `where_clause`.

#### **See Also:**

["References to Partitioned Tables and Indexes"](#) and ["Deleting Rows from a Partition: Example"](#)

#### ***dblink***

Specify the complete or partial name of a database link to a remote database where the object is located. You can delete rows from a remote object only if you are using Oracle Database distributed functionality.

#### **Note:**

Starting with Oracle Database 12c Release 2 (12.2), the `DELETE` statement accepts remote LOB locators as bind variables. Refer to the "Distributed LOBs" chapter in *Oracle Database SecureFiles and Large Objects Developer's Guide* for more information.

#### **See Also:**

["References to Objects in Remote Databases"](#) for information on referring to database links and ["Deleting Rows from a Remote Database: Example"](#)

If you omit `dblink`, then the database assumes that the object is located on the local database.

#### ***subquery\_restriction\_clause***

The `subquery_restriction_clause` lets you restrict the subquery in one of the following ways:

##### **WITH READ ONLY**

Specify `WITH READ ONLY` to indicate that the table or view cannot be updated.

##### **WITH CHECK OPTION**

Specify WITH CHECK OPTION to indicate that Oracle Database prohibits any changes to the table or view that would produce rows that are not included in the subquery. When used in the subquery of a DML statement, you can specify this clause in a subquery in the FROM clause but not in subquery in the WHERE clause.

#### **CONSTRAINT constraint**

Specify the name of the CHECK OPTION constraint. If you omit this identifier, then Oracle automatically assigns the constraint a name of the form SYS\_Cn, where n is an integer that makes the constraint name unique within the database.

#### **See Also:**

["Using the WITH CHECK OPTION Clause: Example"](#)

#### ***table\_collection\_expression***

The *table\_collection\_expression* lets you inform Oracle that the value of *collection\_expression* should be treated as a table for purposes of query and DML operations. The *collection\_expression* can be a subquery, a column, a function, or a collection constructor. Regardless of its form, it must return a collection value—that is, a value whose type is nested table or varray. This process of extracting the elements of a collection is called **collection unnesting**.

The optional plus (+) is relevant if you are joining the TABLE collection expression with the parent table. The + creates an outer join of the two, so that the query returns rows from the outer table even if the collection expression is null.

#### **Note:**

In earlier releases of Oracle, when *collection\_expression* was a subquery, *table\_collection\_expression* was expressed as THE *subquery*. That usage is now deprecated.

You can use a *table\_collection\_expression* in a correlated subquery to delete rows with values that also exist in another table.

#### **See Also:**

["Table Collections: Examples"](#)

#### ***collection\_expression***

Specify a subquery that selects a nested table column from the object from which you are deleting.

#### **Restrictions on the *dml\_table\_expression\_clause* Clause**

This clause is subject to the following restrictions:

- You cannot execute this statement if *table* or the base or master table of *view* or *materialized\_view* contains any domain indexes marked IN\_PROGRESS or FAILED.
- You cannot insert into a partition if any affected index partitions are marked UNUSABLE.
- You cannot specify the ORDER BY clause in the subquery of the *DML\_table\_expression\_clause*.
- You cannot delete from a view except through INSTEAD OF triggers if the defining query of the view contains one of the following constructs:
  - A set operator
  - A DISTINCT operator
  - An aggregate or analytic function
  - A GROUP BY, ORDER BY, MODEL, CONNECT BY, or START WITH clause
  - A collection expression in a SELECT list
  - A subquery in a SELECT list
  - A subquery designated WITH READ ONLY
  - Joins, with some exceptions, as documented in *Oracle Database Administrator's Guide*

If you specify an index, index partition, or index subpartition that has been marked UNUSABLE, then the DELETE statement will fail unless the SKIP\_UNUSABLE\_INDEXES initialization parameter has been set to true.

#### See Also:

[ALTER SESSION](#)

### *t\_alias*

Provide a **correlation name** for the table, view, materialized view, subquery, or collection value to be referenced elsewhere in the statement. This alias is required if the *DML\_table\_expression\_clause* references any object type attributes or object type methods. Table aliases are generally used in DELETE statements with correlated queries.

### *from\_using\_clause*

Use this clause to filter the rows DELETE removes. Specify the join conditions in the *where\_clause*. You can outer join source tables to the target with (+). The target table cannot be the outer table in the join.

You can join many tables, views, and inline views. Specify the join conditions in the *where\_clause* or use the *join\_clause* to join these to each other with ANSI join syntax.

You can specify the same table in the *dml\_table\_expression\_clause* and *from\_using\_clause*. When you do so they must have unique aliases.

### **Example: Delete with Direct-Join**

In this example, the join condition between table *t* and table *s* determines which rows of *t* are deleted:

```
DELETE FROM t
FROM s
WHERE t.t1 = s.s1;
```

If the join condition results in the same target row being selected more than once, the `DELETE` will succeed, and the deletion count will correctly reflect the number of rows deleted.

In a `DELETE` of a join view, one of the tables must be key-preserving. That table is used as the delete target. If there is more than one table that is key-preserving, the first key-preserved table encountered in the `FROM` clause is used as the delete target. If no such table exists, error `ORA-01752` is raised. There is no such restriction in direct join syntax, since it is clear what the delete target is.

Direct joins for `DELETE` have the same semantics and restrictions as `SELECT` in the `from_clause` and `where_clause`. Triggers on the target table fire as normal.

### Restrictions

- You cannot specify ANSI join syntax using the `dml_table_expression_clause`. However, you can specify ANSI join syntax between the tables specified in the `FROM` clause. Right and full outer joins are not allowed.
- You can use a lateral view in the `FROM` clause, but it cannot reference a column from the delete target. It may be outer-joined.
- You can only specify one table, view, or materialized view in `dml_table_expression_clause` when the `from_using_clause` is present.
- The `hint` clause can be used to specify instructions to the optimizer for joins involving the `from_using_clause`

### `where_clause`

Use the `where_clause` to delete only rows that satisfy the condition. The condition can reference the object from which you are deleting and can contain a subquery. You can delete rows from a remote object only if you are using Oracle Database distributed functionality. Refer to [Conditions](#) for the syntax of `condition`.

If this clause contains a `subquery` that refers to remote objects, then the `DELETE` operation can run in parallel as long as the reference does not loop back to an object on the local database. However, if the `subquery` in the `DML_table_expression_clause` refers to any remote objects, then the `DELETE` operation will run serially without notification. Refer to the [parallel\\_clause](#) in the [CREATE TABLE](#) documentation for additional information.

If you omit `dblink`, then the database assumes that the table or view is located on the local database.

If you omit the `where_clause`, then the database deletes all rows of the object.

### `returning_clause`

This clause lets you return values from deleted columns, and thereby eliminate the need to issue a `SELECT` statement following the `DELETE` statement.

The returning clause retrieves the rows affected by a DML statement. You can specify this clause for tables and materialized views and for views with a single base table.

When operating on a single row, a DML statement with a *returning clause* can retrieve column expressions using the affected row, rowid, and `REFs` to the affected row and store them in host variables or PL/SQL variables.

When operating on multiple rows, a DML statement with the *returning clause* stores values from expressions, rowids, and `REFs` involving the affected rows in bind arrays.

### ***expr***

Each item in the *expr* list must be a valid expression syntax.

### **INTO**

The `INTO` clause indicates that the values of the changed rows are to be stored in the variable(s) specified in *data\_item* list.

### ***data\_item***

Each *data\_item* is a host variable or PL/SQL variable that stores the retrieved *expr* value.

For each expression in the `RETURNING` list, you must specify a corresponding type-compatible PL/SQL variable or host variable in the `INTO` list.

### **Restrictions on the RETURNING Clause**

The following restrictions apply to the `RETURNING` clause:

- The *expr* is restricted as follows:
  - For `UPDATE` and `DELETE` statements each *expr* must be a simple expression or a single-set aggregate function expression. You cannot combine simple expressions and single-set aggregate function expressions in the same *returning clause*. For `INSERT` statements, each *expr* must be a simple expression. Aggregate functions are not supported in an `INSERT` statement `RETURNING` clause.
  - Single-set aggregate function expressions cannot include the `DISTINCT` keyword.
- If the *expr* list contains a primary key column or other `NOT NULL` column, then the update statement fails if the table has a `BEFORE UPDATE` trigger defined on it.
- You cannot specify the *returning clause* for a multitable insert.
- You cannot use this clause with parallel DML or with remote objects.
- You cannot retrieve `LONG` types with this clause.
- You cannot specify this clause for a view on which an `INSTEAD OF` trigger has been defined.

#### **See Also:**

- *Oracle Database PL/SQL Language Reference* for information on using the `BULK COLLECT` clause to return multiple values to collection variables
- "[Using the RETURNING Clause: Example](#)"

### ***error\_logging\_clause***

The *error\_logging\_clause* has the same behavior in DELETE statement as it does in an INSERT statement. Refer to the INSERT statement *error\_logging\_clause* for more information.

#### See Also:

["Inserting Into a Table with Error Logging: Example"](#)

## Examples

### **Deleting Rows: Examples**

The following statement deletes all rows from the sample table oe.product\_descriptions where the value of the language\_id column is AR:

```
DELETE FROM product_descriptions
WHERE language_id = 'AR';
```

The following statement deletes from the sample table hr.employees purchasing clerks whose commission rate is less than 10%:

```
DELETE FROM employees
WHERE job_id = 'SA_REP'
AND commission_pct < .2;
```

The following statement has the same effect as the preceding example, but uses a subquery:

```
DELETE FROM (SELECT * FROM employees)
WHERE job_id = 'SA_REP'
AND commission_pct < .2;
```

### **Deleting Rows from a Remote Database: Example**

The following statement deletes specified rows from the locations table owned by the user hr on a database accessible by the database link remote:

```
DELETE FROM hr.locations@remote
WHERE location_id > 3000;
```

### **Deleting Nested Table Rows: Example**

For an example that deletes nested table rows, refer to "[Table Collections: Examples](#)".

### **Deleting Rows from a Partition: Example**

The following example removes rows from partition sales\_q1\_1998 of the sh.sales table:

```
DELETE FROM sales PARTITION (sales_q1_1998)
WHERE amount_sold > 1000;
```

### **Using the RETURNING Clause: Example**

The following example returns column `salary` from the deleted rows and stores the result in bind variable `:bnd1`. The bind variable must already have been declared.

```
DELETE FROM employees
  WHERE job_id = 'SA_REP'
    AND hire_date + TO_YMINTERVAL('01-00') < SYSDATE
  RETURNING salary INTO :bnd1;
```

### **Deleting Data from a Table: Example**

The following statements create a table named `product_price_history` and insert data into it:

```
CREATE TABLE product_price_history (
  product_id          INTEGER NOT NULL,
  price                INTEGER NOT NULL,
  currency_code        VARCHAR2(3 CHAR) NOT NULL,
  effective_from_date DATE NOT NULL,
  effective_to_date   DATE,
  CONSTRAINT product_price_history_pk
    PRIMARY KEY (product_id, currency_code, effective_from_date)
) PARTITION BY RANGE (effective_from_date) (
  PARTITION p0 VALUES less than (DATE'2015-01-02'),
  PARTITION p1 VALUES less than (DATE'2015-01-03'),
  PARTITION p2 VALUES less than (DATE'2015-01-04')
);

INSERT INTO product_price_history
WITH prices AS (
  SELECT 1, 100, 'USD', DATE'2015-01-01', DATE'2015-01-02'
  FROM dual UNION ALL
  SELECT 1, 60, 'GBP', DATE'2015-01-01', DATE'2015-01-02'
  FROM dual UNION ALL
  SELECT 1, 110, 'EUR', DATE'2015-01-01', DATE'2015-01-02'
  FROM dual UNION ALL
  SELECT 1, 101, 'USD', DATE'2015-01-02', DATE'2015-01-03'
  FROM dual UNION ALL
  SELECT 1, 62, 'GBP', DATE'2015-01-02', DATE'2015-01-03'
  FROM dual UNION ALL
  SELECT 1, 109, 'EUR', DATE'2015-01-02', DATE'2015-01-03'
  FROM dual UNION ALL
  SELECT 1, 105, 'USD', DATE'2015-01-03', NULL
  FROM dual UNION ALL
  SELECT 1, 61, 'GBP', DATE'2015-01-03', NULL
  FROM dual UNION ALL
  SELECT 1, 107, 'EUR', DATE'2015-01-03', NULL
  FROM dual UNION ALL
  SELECT 2, 30, 'USD', DATE'2015-01-01', DATE'2015-01-03'
  FROM dual UNION ALL
  SELECT 2, 33, 'USD', DATE'2015-01-03', NULL
  FROM dual UNION ALL
  SELECT 3, 100, 'GBP', DATE'2015-01-03', NULL
  FROM dual
)
SELECT *
FROM prices;
```

The following statement deletes the rows from the table `product_price_history` where `product_id` is 3:

```
DELETE FROM product_price_history WHERE product_id = 3;
```

The following procedure deletes the rows from the product\_price\_history where product\_id is 2 and effective\_to\_date is NULL:

```

DECLARE
    currency product_price_history.currency_code%TYPE;
BEGIN
    DELETE product_price_history
    WHERE product_id = 2
    AND effective_to_date IS NULL
    returning currency_code INTO currency;

    dbms_output.Put_line(currency);
END;

```

USD

The following statement deletes the rows from the table product\_price\_history where currency\_code is 'EUR':

```
DELETE (SELECT * FROM product_price_history) WHERE currency_code = 'EUR';
```

The following statement uses a subquery to delete rows from product\_price\_history:

```

DELETE product_price_history pp
WHERE (product_id, currency_code, effective_from_date)
    IN (SELECT product_id, currency_code, Max(effective_from_date)
        FROM product_price_history
        GROUP BY product_id, currency_code);

```

The following statement uses partitions to delete rows from product\_price\_history:

```
DELETE product_price_history partition (p1);
```

The following statement displays the table information:

```

SELECT * FROM product_price_history;

PRODUCT_ID      PRICE CUR EFFECTIVE EFFECTIVE
-----  -----
1          100 USD 01-JAN-15 02-JAN-15
1          60 GBP 01-JAN-15 02-JAN-15

```

The following statement deletes all rows from product\_price\_history:

```
DELETE product_price_history;
```

## DISASSOCIATE STATISTICS

### Purpose

Use the DISASSOCIATE STATISTICS statement to disassociate default statistics or a statistics type from columns, standalone functions, packages, types, domain indexes, or indextypes.

 See Also:

[ASSOCIATE STATISTICS](#) for more information on statistics type associations

### Prerequisites

To issue this statement, you must have the appropriate privileges to alter the underlying table, function, package, type, domain index, or indextype.

### Syntax

*disassociate\_statistics ::=*

### Semantics

**FROM COLUMNS | FUNCTIONS | PACKAGES | TYPES | INDEXES | INDEXTYPES**

Specify one or more columns, standalone functions, packages, types, domain indexes, or indextypes from which you are disassociating statistics.

If you do not specify *schema*, then Oracle Database assumes the object is in your own schema.

If you have collected user-defined statistics on the object, then the statement fails unless you specify FORCE.

## FORCE

Specify **FORCE** to remove the association regardless of whether any statistics exist for the object using the statistics type. If statistics do exist, then the statistics are deleted before the association is deleted.

 **Note:**

When you drop an object with which a statistics type has been associated, Oracle Database automatically disassociates the statistics type with the **FORCE** option and drops all statistics that have been collected with the statistics type.

## Examples

### Disassociating Statistics: Example

This statement disassociates statistics from the `emp_mgmt` package. See *Oracle Database PL/SQL Language Reference* for the example that creates this package in the `hr` schema.

```
DISASSOCIATE STATISTICS FROM PACKAGES hr.emp_mgmt;
```

# DROP ANALYTIC VIEW

## Purpose

Use the `DROP ANALYTIC VIEW` statement to drop an analytic view. An `ANALYTIC VIEW` object is a component of analytic views.

## Prerequisites

To drop an analytic view in your own schema, you must have the `DROP ANALYTIC VIEW` system privilege. To drop an analytic view in another user's schema, you must have the `DROP ANY ANALYTIC VIEW` system privilege.

## Syntax

`drop_analytic_view ::=`

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

***schema***

Specify the schema in which the analytic view exists. If you do not specify a schema, then Oracle Database looks for the analytic view in your own schema.

***analytic\_view\_name***

Specify the name of the analytic view to drop.

**Example**

The following statement drops the specified analytic view object:

```
DROP ANALYTIC VIEW sales_av;
```

## DROP ATTRIBUTE DIMENSION

**Purpose**

Use the `DROP ATTRIBUTE DIMENSION` statement to drop an attribute dimension. An `ATTRIBUTE DIMENSION` object is a component of analytic views.

**Prerequisites**

To drop an attribute dimension in your own schema, you must have the `DROP ATTRIBUTE DIMENSION` system privilege. To drop an analytic view in another user's schema, you must have the `DROP ANY ATTRIBUTE DIMENSION` system privilege.

**Syntax**

`drop_attribute_dimension ::=`

**Semantics****IF EXISTS**

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

***schema***

Specify the schema in which the attribute dimension exists. If you do not specify a schema, then Oracle Database looks for the attribute dimension in your own schema.

***attr\_dimension\_name***

Specify the name of the attribute dimension to drop.

### Example

The following statement drops the specified attribute dimension object:

```
DROP ATTRIBUTE DIMENSION product_attr_dim;
```

## DROP AUDIT POLICY (Unified Auditing)

This section describes the `DROP AUDIT POLICY` statement for **unified auditing**. This type of auditing is new beginning with Oracle Database 12c and provides a full set of enhanced auditing features. Refer to *Oracle Database Security Guide* for more information on unified auditing.

### Purpose

Use the `DROP AUDIT POLICY` statement to remove a unified audit policy from the database.

#### See Also:

- [CREATE AUDIT POLICY \(Unified Auditing\)](#)
- [ALTER AUDIT POLICY \(Unified Auditing\)](#)
- [AUDIT \(Unified Auditing\)](#)
- [NOAUDIT \(Unified Auditing\)](#)

### Prerequisites

You must have the `AUDIT SYSTEM` system privilege or the `AUDIT_ADMIN` role.

To drop a common unified audit policy, the current container must be the root and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role. To drop a local unified audit policy, the current container must be the container in which the audit policy was created and you must have the commonly granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` common role, or you must have the locally granted `AUDIT SYSTEM` privilege or the `AUDIT_ADMIN` local role in the container.

### Syntax

*drop\_audit\_policy ::=*

### Semantics

#### *policy*

Specify the name of the unified audit policy you want to drop. The policy must have been created using the `CREATE AUDIT POLICY` statement.

You can find the names of all unified audit policies by querying the `AUDIT_UNIFIED_POLICIES` view and the names of all *enabled* unified audit policies by querying the `AUDIT_UNIFIED_ENABLED_POLICIES` view

### Restriction on Dropping Unified Audit Policies

You cannot drop an enabled unified audit policy. You must first disable the policy using the `NOAUDIT` statement.

#### See Also:

- [CREATE AUDIT POLICY \(Unified Auditing\)](#)
- *Oracle Database Reference* for more information on the `AUDIT_UNIFIED_POLICIES` and `AUDIT_UNIFIED_ENABLED_POLICIES` views

### Examples

#### Dropping a Unified Audit Policy: Example

The following statement drops unified audit policy `table_pol`:

```
DROP AUDIT POLICY table_pol;
```

## DROP CLUSTER

### Purpose

Use the `DROP CLUSTER` clause to remove a cluster from the database.

#### Note:

When you drop a cluster, any tables in the recycle bin that were once part of that cluster are purged from the recycle bin and can no longer be recovered with a `FLASHBACK TABLE` operation.

You cannot uncluster an individual table. Instead you must perform these steps:

1. Create a new table with the same structure and contents as the old one, but with no `CLUSTER` clause.
2. Drop the old table.
3. Use the `RENAME` statement to give the new table the name of the old one.
4. Grant privileges on the new unclustered table. Grants on the old clustered table do not apply.

**See Also:**

[CREATE TABLE](#), [DROP TABLE](#), [RENAME](#), [GRANT](#) for information on these steps

**Prerequisites**

The cluster must be in your own schema or you must have the DROP ANY CLUSTER system privilege.

**Syntax**

*drop\_cluster ::=*

**Semantics****IF EXISTS**

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

***schema***

Specify the schema containing the cluster. If you omit `schema`, then the database assumes the cluster is in your own schema.

***cluster***

Specify the name of the cluster to be dropped. Dropping a cluster also drops the cluster index and returns all cluster space, including data blocks for the index, to the appropriate tablespace(s).

**INCLUDING TABLES**

Specify `INCLUDING TABLES` to drop all tables that belong to the cluster.

**CASCADE CONSTRAINTS**

Specify `CASCADE CONSTRAINTS` to drop all referential integrity constraints from tables outside the cluster that refer to primary and unique keys in tables of the cluster. If you omit this clause and such referential integrity constraints exist, then the database returns an error and does not drop the cluster.

## Examples

### Dropping a Cluster: Examples

The following examples drop the clusters created in the "Examples" section of CREATE CLUSTER.

The following statements drops the language cluster:

```
DROP CLUSTER language;
```

The following statement drops the personnel cluster as well as tables dept\_10 and dept\_20 and any referential integrity constraints that refer to primary or unique keys in those tables:

```
DROP CLUSTER personnel
  INCLUDING TABLES
    CASCADE CONSTRAINTS;
```

# 16

## SQL Statements: DROP CONTEXT to DROP JAVA

This chapter contains the following SQL statements:

- [DROP CONTEXT](#)
- [DROP DATABASE](#)
- [DROP DATABASE LINK](#)
- [DROP DIMENSION](#)
- [DROP DIRECTORY](#)
- [DROP DISKGROUP](#)
- [DROP EDITION](#)
- [DROP FLASHBACK ARCHIVE](#)
- [DROP FUNCTION](#)
- [DROP HIERARCHY](#)
- [DROP INDEX](#)
- [DROP INDEXTYPE](#)
- [DROP INMEMORY JOIN GROUP](#)
- [DROP JAVA](#)

### DROP CONTEXT

#### Purpose

Use the `DROP CONTEXT` statement to remove a context namespace from the database.

Removing a context namespace does not invalidate any context under that namespace that has been set for a user session. However, the context will be invalid when the user next attempts to set that context.

#### See Also:

[CREATE CONTEXT](#) and *Oracle Database Security Guide* for more information on contexts

#### Prerequisites

You must have the `DROP ANY CONTEXT` system privilege.

## Syntax

*drop\_context ::=*

## Semantics

### *namespace*

Specify the name of the context namespace to drop. You cannot drop the built-in namespace `USERENV`.

#### See Also:

[SYS\\_CONTEXT](#) for information on the `USERENV` namespace

## Examples

### Dropping an Application Context: Example

The following statement drops the context created in [CREATE CONTEXT](#):

```
DROP CONTEXT hr_context;
```

# DROP DATABASE

## Purpose

#### Note:

You cannot roll back a `DROP DATABASE` statement.

Use the `DROP DATABASE` statement to drop the database. This statement is useful when you want to drop a test database or drop an old database after successful migration to a new host.

#### See Also:

[Oracle Database Backup and Recovery User's Guide](#) for more information on dropping the database

## Prerequisites

You must have the `SYSDBA` system privilege to issue this statement. The database must be mounted in exclusive and restricted mode, and it must be closed.

## Syntax

*drop\_database ::=*

## Semantics

When you issue this statement, Oracle Database drops the database and deletes all control files and data files listed in the control file. If the database used a server parameter file (spfile), then the spfile is also deleted.

Archived logs and backups are not removed, but you can use Recovery Manager (RMAN) to remove them. If the database is on raw disks, then this statement does not delete the actual raw disk special files.

# DROP DATABASE LINK

## Purpose

Use the `DROP DATABASE LINK` statement to remove a database link from the database.

**See Also:**

[CREATE DATABASE LINK](#) for information on creating database links

## Prerequisites

A private database link must be in your own schema. To drop a `PUBLIC` database link, you must have the `DROP PUBLIC DATABASE LINK` system privilege.

## Syntax

*drop\_database\_link ::=*

## Semantics

### PUBLIC

You must specify `PUBLIC` to drop a `PUBLIC` database link.

### ***dblink***

Specify the name of the database link to be dropped.

#### **Restriction on Dropping Database Links**

You cannot drop a database link in another user's schema, and you cannot qualify *dblink* with the name of a schema, because periods are permitted in names of database links. Therefore, Oracle Database interprets the entire name, such as `ralph.linktosales`, as the name of a database link in your schema rather than as a database link named `linktosales` in the schema `ralph`.

#### **IF EXISTS**

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

#### **Examples**

##### **Dropping a Database Link: Example**

The following statement drops the public database link named `remote`, which was created in "[Defining a Public Database Link: Example](#)":

```
DROP PUBLIC DATABASE LINK remote;
```

## **DROP DIMENSION**

#### **Purpose**

Use the `DROP DIMENSION` statement to remove the named dimension.

This statement does not invalidate materialized views that use relationships specified in dimensions. However, requests that have been rewritten by query rewrite may be invalidated, and subsequent operations on such views may execute more slowly.

#### **See Also:**

- [CREATE DIMENSION](#) and [ALTER DIMENSION](#) for information on creating and modifying a dimension
- *Oracle Database Concepts* for general information about dimensions

#### **Prerequisites**

The dimension must be in your own schema or you must have the `DROP ANY DIMENSION` system privilege to use this statement.

## Syntax

*drop\_dimension ::=*

## Semantics

### *schema*

Specify the name of the schema in which the dimension is located. If you omit *schema*, then Oracle Database assumes the dimension is in your own schema.

### *dimension*

Specify the name of the dimension you want to drop. The dimension must already exist.

## Examples

### Dropping a Dimension: Example

This example drops the `sh.customers_dim` dimension:

```
DROP DIMENSION customers_dim;
```

### See Also:

"[Creating a Dimension: Examples](#)" and "[Modifying a Dimension: Examples](#)" for examples of creating and modifying this dimension

# DROP DIRECTORY

## Purpose

Use the `DROP DIRECTORY` statement to remove a directory object from the database.

### See Also:

[CREATE DIRECTORY](#) for information on creating a directory

## Prerequisites

To drop a directory, you must have the `DROP ANY DIRECTORY` system privilege.

 **Note:**

Do not drop a directory when files in the associated file system are being accessed by PL/SQL or OCI programs.

## Syntax

*drop\_directory*::=

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### *directory\_name*

Specify the name of the directory database object to be dropped.

Oracle Database removes the directory object but does not delete the associated operating system directory on the server file system.

## Examples

### Dropping a Directory: Example

The following statement drops the directory object `bfile_dir`:

```
DROP DIRECTORY bfile_dir;
```

 **See Also:**

["Creating a Directory: Examples"](#)

# DROP DISKGROUP

## Note:

This SQL statement is valid only if you are using Oracle ASM and you have started an Oracle ASM instance. You must issue this statement from within the Oracle ASM instance, not from a normal database instance. For information on starting an Oracle ASM instance, refer to *Oracle Automatic Storage Management Administrator's Guide*.

## Purpose

The `DROP DISKGROUP` statement lets you drop an Oracle ASM disk group along with all the files in the disk group. Oracle ASM first ensures that no files in the disk group are open. It then drops the disk group and all its member disks and clears the disk header.

## See Also:

- [CREATE DISKGROUP](#) and [ALTER DISKGROUP](#) for information on creating and modifying disk groups
- *Oracle Automatic Storage Management Administrator's Guide* for information on Oracle ASM and using disks groups to simplify database administration

## Prerequisites

You must have the `SYSASM` system privilege and you must have an Oracle ASM instance started, from which you issue this statement. The disk group to be dropped must be mounted.

## Syntax

`drop_diskgroup ::=`

## Semantics

### `diskgroup_name`

Specify the name of the disk group you want to drop.

## INCLUDING CONTENTS

Specify **INCLUDING CONTENTS** to confirm that Oracle ASM should drop all the files in the disk group. You must specify this clause if the disk group contains any files.

### FORCE

This clause clears the headers on the disk belonging to a disk group that cannot be mounted by the Oracle ASM instance. The disk group cannot be mounted by any instance of the database.

The Oracle ASM instance first determines whether the disk group is being used by any other Oracle ASM instance using the same storage subsystem. If it is being used, and if the disk group is in the same cluster, or on the same node, then the statement fails. If the disk group is in a different cluster, then the system further checks to determine whether the disk group is mounted by any instance in the other cluster. If it is mounted elsewhere, then the statement fails. However, this latter check is not as definitive as the checks for disk groups in the same cluster. Therefore, use this clause with caution.

## EXCLUDING CONTENTS

Specify **EXCLUDING CONTENTS** to ensure that Oracle ASM drops the disk group only when the disk group is empty. This is the default. If the disk group is not empty, then an error will be returned.

### Examples

#### Dropping a Diskgroup: Example

The following statement drops the Oracle ASM disk group `dgroup_01`, which was created in "[Creating a Diskgroup: Example](#)", and all of the files in the disk group:

```
DROP DISKGROUP dgroup_01 INCLUDING CONTENTS;
```

## DROP DOMAIN

### Purpose

Use this statement to drop a domain, thereby disassociating the domain from all its dependent objects.

### Prerequisites

The domain must be in your own schema or you must have the `DROP ANY DOMAIN` system privilege.

### Syntax

`drop_domain ::=`

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop a domain that exists.

You cannot specify `IF NOT EXISTS` with `DROP DOMAIN`. This results in the following error:

ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

You can drop a domain by specifying its domain name and disassociate it from all its dependent columns. In the following example `email` is the name of a domain name:

```
DROP DOMAIN email;
```

If a domain is associated with columns, `DROP DOMAIN domain_name` fails with ORA-11502: The domain `<domain_name>` to be dropped has dependent objects. This includes any tables in the recyclebin.

You can additionally drop a domain by specifying two optional keywords: either `FORCE` or `FORCE PRESERVE` which have different meanings:

### FORCE

`DROP DOMAIN domain_name FORCE` disassociates the domain from all its dependent columns. This includes dropping all constraints on columns that were inherited from the domain. Defaults inherited from the domain are also dropped unless these defaults were set specifically on columns.

If you must drop a domain and have dependent tables in the recyclebin, you must use the `FORCE` option.

### FORCE PRESERVE

Use `DROP DOMAIN domain_name FORCE PRESERVE` if you want to preserve domain defaults and domain constraints on columns inherited from the domain. You must first specify `FORCE`, in order to specify the `PRESERVE` option. Use this option if you want to temporarily drop the domain and recreate it later with new data and the former dependent columns. In this case you want to ensure that the table data continues to be consistent with the domain definition with all the constraints and defaults on columns inherited from the domain preserved. If you drop a domain with `FORCE PRESERVE` and later recreate the domain and reassociate the column with it, you can end up with a second constraint. In this case, use `ALTER TABLE DROP CONSTRAINT` to drop the second constraint.

If there are no tables or materialized views with columns of the given domain, then `DROP DOMAIN` will invalidate any SQL dependent statements and remove the domain object from the catalog. In this case you can specify `FORCE` and `FORCE PRESERVE` without affecting the domain or the domain's dependent objects.

If there are tables or materialized views with columns of the given domain, `DROP DOMAIN` without the `FORCE` option will fail without affecting the domain or domain's dependent objects.

If there are tables or materialized views with columns of the given domain, `DROP DOMAIN FORCE` will do the following:

- Remove the default expression from any dependent column, if the column has a default expression that was only set as a domain default. If the default expression was added on the column and set as domain default, then default on the column is preserved.

- Remove the domain annotations from all dependent columns
- Preserve collation on any domain dependent columns
- Invalidate all SQL dependent statements in the cursor cache.
- Materialized views (MVs) that reference domain functions like `DOMAIN_DISPLAY`, `DOMAIN_ORDER`, `DOMAIN_NAME` will be invalidated so they can be fully refreshed. MVs that reference columns of a given domain will not be invalidated .
- Remove the domain successfully.

If there are flexible domains referencing the domain, then `DROP DOMAIN` without the `FORCE` option will raise an error, while `DROP DOMAIN FORCE` will drop all flexible dependent domains in `FORCE` mode also.

### Examples

The following example drops the domain `day_of_week`. If there are any columns associated with the domain the statement will raise `ORA-11502` and the domain will still be present:

```
DROP DOMAIN day_of_week;
```

The following statement drops the domain `day_of_week`. If there are any columns associated with it, the columns will inherit any defaults and constraints from the domain:

```
DROP DOMAIN day_of_week FORCE PRESERVE;
```

## DROP EDITION

### Purpose

Use the `DROP EDITION` statement to drop an edition, along with all actual editionable objects it contains. An actual editionable object is an editionable object that has been created or modified in an edition.

#### See Also:

[CREATE EDITION](#) for a listing of editionable object types

### Prerequisites

You must have the `DROP ANY EDITION` system privilege, granted either directly or through a role.

### Syntax

***drop\_edition::=***

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing edition.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

Objects that are not editionable, or that are editionable but have not been actualized in the current edition, are not dropped.

You must specify `CASCADE` if the specified edition contains any actual editionable objects.

### Restrictions

This statement is subject to the following conditions and restrictions:

- The specified edition cannot have both a parent edition and a child edition.
- `DROP EDITION` will fail if you attempt to drop the default edition.
- `DROP EDITION` will fail if you attempt to drop the root edition and the recycle bin contains at least one object that used to be in that edition before it was dropped. Under these circumstances, even `DROP EDITION CASCADE` will fail. In this case, you can purge all objects from the recycle bin with the `PURGE DBA_RECYCLEBIN` statement and then drop the edition. Refer to [PURGE](#) for more information.

`DROP EDITION` will also fail if you attempt to drop the leaf edition and the recycle bin contains at least one object that used to be in that edition before it was dropped. However, under these circumstances, `DROP EDITION CASCADE` will succeed.

The only type of editioned object that might be in the recycle bin is a trigger.

### See Also:

- [Oracle Database Development Guide](#)
- [Oracle Database PL/SQL Packages and Types Reference](#)

## Examples

For examples that use this statement, refer to [CREATE EDITION](#).

# DROP FLASHBACK ARCHIVE

### Purpose

Use the `DROP FLASHBACK ARCHIVE` clause to remove a flashback archive from the system. This statement removes the flashback archive and all the historical data in it, but does not drop the tablespaces that were used by the flashback archive.

## Prerequisites

You must have the FLASHBACK ARCHIVE ADMINISTER system privilege to drop a flashback archive.

## Syntax

*drop\_flashback\_archive*::=

## Semantics

### *flashback\_archive*

Specify the name of the flashback archive you want to drop.

#### See Also:

[CREATE FLASHBACK ARCHIVE](#) for information on creating flashback archives and for some simple examples of using flashback archives

# DROP FUNCTION

## Purpose

Functions are defined using PL/SQL. Refer to *Oracle Database PL/SQL Language Reference* for complete information on creating, altering, and dropping functions.

Use the `DROP FUNCTION` statement to remove a standalone stored function from the database.

#### Note:

Do not use this statement to remove a function that is part of a package. Instead, either drop the entire package using the `DROP PACKAGE` statement or redefine the package without the function using the `CREATE PACKAGE` statement with the `OR REPLACE` clause.

## Prerequisites

The function must be in your own schema or you must have the `DROP ANY PROCEDURE` system privilege.

## Syntax

*drop\_function ::=*

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### schema

Specify the schema containing the function. If you omit `schema`, then Oracle Database assumes the function is in your own schema.

### function\_name

Specify the name of the function to be dropped.

Oracle Database invalidates any local objects that depend on, or call, the dropped function. If you subsequently reference one of these objects, then the database tries to recompile the object and returns an error if you have not re-created the dropped function.

If any statistics types are associated with the function, then the database disassociates the statistics types with the `FORCE` option and drops any user-defined statistics collected with the statistics type.

### See Also:

- *Oracle Database Concepts* for more information on how Oracle Database maintains dependencies among schema objects, including remote objects
- [ASSOCIATE STATISTICS](#) and [DISASSOCIATE STATISTICS](#) for more information on statistics type associations

## Examples

### Dropping a Function: Example

The following statement drops the function `SecondMax` in the sample schema `oe` and invalidates all objects that depend upon `SecondMax`:

```
DROP FUNCTION oe.SecondMax;
```

 See Also:

*Oracle Database PL/SQL Language Reference* for the example that creates the `SecondMax` function

# DROP HIERARCHY

## Purpose

Use the `DROP HIERARCHY` statement to drop a hierarchy. A `HIERARCHY` object is a component of analytic views.

## Prerequisites

To drop a hierarchy in your own schema, you must have the `DROP HIERARCHY` system privilege. To drop a hierarchy in another user's schema, you must have the `DROP ANY HIERARCHY` system privilege.

## Syntax

*drop\_hierarchy*::=

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### *schema*

Specify the schema in which the hierarchy exists. If you do not specify a schema, then Oracle Database looks for the hierarchy in your own schema.

### *hierarchy\_name*

Specify the name of the hierarchy to drop.

## Example

The following statement drops the specified hierarchy object:

```
DROP HIERARCHY product_hier;
```

# DROP INDEX

## Purpose

Use the `DROP INDEX` statement to remove an index or domain index from the database.

When you drop a global partitioned index, a range-partitioned index, or a hash-partitioned index, all the index partitions are also dropped. If you drop a composite-partitioned index, then all the index partitions and subpartitions are also dropped.

In addition, when you drop a domain index:

- Oracle Database invokes the appropriate routine.
- If any statistics are associated with the domain index, then Oracle Database disassociates the statistics types with the `FORCE` clause and removes the user-defined statistics collected with the statistics type.

### See Also:

- *Oracle Database Data Cartridge Developer's Guide* for information on the routines
- [CREATE INDEX](#) and [ALTER INDEX](#) for information on creating and modifying an index
- The `domain_index_clause` of [CREATE INDEX](#) for more information on domain indexes
- [ASSOCIATE STATISTICS](#) and [DISASSOCIATE STATISTICS](#) for more information on statistics type associations

## Prerequisites

The index must be in your own schema or you must have the `DROP ANY INDEX` system privilege.

## Syntax

`drop_index ::=`

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### *schema*

Specify the schema containing the index. If you omit `schema`, then Oracle Database assumes the index is in your own schema.

### *index*

Specify the name of the index to be dropped. When the index is dropped, all data blocks allocated to the index are returned to the tablespace that contained the index.

### ONLINE

Specify `ONLINE` to indicate that DML operations on the table or partition will be allowed while dropping the index.

### FORCE

`FORCE` applies only to domain indexes. This clause drops the domain index even if the `indxtype` routine invocation returns an error or the index is marked `IN PROGRESS`. Without `FORCE`, you cannot drop a domain index if its `indxtype` routine invocation returns an error or the index is marked `IN PROGRESS`.

#### Note:

When dropping a domain index with `FORCE` option, the index will be dropped regardless of any errors happening in the `indxtype` routine. The errors raised by the `indxtype` routine are not reported.

Only use the `FORCE` option when the index or index partitions are marked `IN PROGRESS` or when `DROP INDEX` has already failed.

### { DEFERRED | IMMEDIATE } INVALIDATION

This clause lets you control when the database invalidates dependent cursors while dropping the index. It has the same semantics here as for the `ALTER INDEX` statement, with the following addition: When you drop an index with `DEFERRED INVALIDATION`, Oracle database will immediately invalidate any DML statement or query that references the dropped index in its plan.

See `{ DEFERRED | IMMEDIATE } INVALIDATION` in the documentation on `ALTER INDEX` for the full semantics of this clause.

### Restrictions on Dropping Indexes

The following restrictions apply to dropping indexes:

- You cannot drop a domain index if the index or any of its index partitions is marked IN\_PROGRESS.
- You cannot specify the ONLINE clause when dropping a domain index, a cluster index, or an index on a queue table.

### Examples

#### Dropping an Index: Example

This statement drops an index named `ord_customer_ix_demo`, which was created in "Compressing an Index: Example":

```
DROP INDEX ord_customer_ix_demo;
```

## DROP INDEXTYPE

### Purpose

Use the `DROP INDEXTYPE` statement to drop an indextype as well as any association with a statistics type.

#### See Also:

[CREATE INDEXTYPE](#) for more information on indextypes

### Prerequisites

The indextype must be in your own schema or you must have the `DROP ANY INDEXTYPE` system privilege.

### Syntax

`drop_indextype ::=`

### Semantics

#### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

#### schema

Specify the schema containing the indextype. If you omit `schema`, then Oracle Database assumes the indextype is in your own schema.

**indextype**

Specify the name of the indextype to be dropped.

If any statistics types have been associated with indextype, then the database disassociates the statistics type from the indextype and drops any statistics that have been collected using the statistics type.

 **See Also:**

[ASSOCIATE STATISTICS](#) and [DISASSOCIATE STATISTICS](#) for more information on statistics associations

**FORCE**

Specify **FORCE** to drop the indextype even if the indextype is currently being referenced by one or more domain indexes. Oracle Database marks those domain indexes **INVALID**. Without **FORCE**, you cannot drop an indextype if any domain indexes reference the indextype.

**Examples****Dropping an Indextype: Example**

The following statement drops the indextype `position_indextype`, created in "Using Extensible Indexing", and marks `INVALID` any domain indexes defined on this indextype:

```
DROP INDEXTYPE position_indextype FORCE;
```

## DROP INMEMORY JOIN GROUP

**Purpose**

Use the `DROP INMEMORY JOIN GROUP` statement to remove a join group from the database.

 **See Also:**

- [CREATE INMEMORY JOIN GROUP](#) and [ALTER INMEMORY JOIN GROUP](#)
- *Oracle Database In-Memory Guide* for more information on join groups

**Prerequisites**

If the join group is in another user's schema, then you must have the `DROP ANY TABLE` system privilege.

## Syntax

*drop\_inmemory\_join\_group ::=*

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### schema

Specify the schema containing the join group. If you omit `schema`, then the database assumes the join group is in your own schema.

### join\_group

Specify the name of the join group to be dropped.

You can view existing join groups by querying the `DBA_JOINGROUPS` or `USER_JOINGROUPS` data dictionary view. Refer to *Oracle Database Reference* for more information on these views.

## Examples

The following statement drops the join group `prod_id1`:

```
DROP INMEMORY JOIN GROUP prod_id1;
```

# DROP JAVA

## Purpose

Use the `DROP JAVA` statement to drop a Java source, class, or resource schema object.

### See Also:

- [CREATE JAVA](#) for information on creating Java objects
- *Oracle Database Java Developer's Guide* for more information on resolving Java sources, classes, and resources

## Prerequisites

The Java source, class, or resource must be in your own schema or you must have the `DROP ANY PROCEDURE` system privilege. You also must have the `EXECUTE` object privilege on Java classes to use this command.

## Syntax

`drop_java::=`

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### JAVA SOURCE

Specify `SOURCE` to drop a Java source schema object and all Java class schema objects derived from it.

### JAVA CLASS

Specify `CLASS` to drop a Java class schema object.

### JAVA RESOURCE

Specify `RESOURCE` to drop a Java resource schema object.

### `object_name`

Specify the name of an existing Java class, source, or resource schema object. Enclose the `object_name` in double quotation marks to preserve lower- or mixed-case names.

## Examples

### Dropping a Java Class Object: Example

The following statement drops the Java class `Agent`, created in "Creating a Java Class Object: Example":

```
DROP JAVA CLASS "Agent";
```

# SQL Statements: DROP LIBRARY to DROP SYNONYM

This chapter contains the following SQL statements:

- [DROP LIBRARY](#)
- [DROP LOCKDOWN PROFILE](#)
- [DROP MATERIALIZED VIEW](#)
- [DROP MATERIALIZED VIEW LOG](#)
- [DROP MATERIALIZED ZONEMAP](#)
- [DROP OPERATOR](#)
- [DROP OUTLINE](#)
- [DROP PACKAGE](#)
- [DROP PLUGGABLE DATABASE](#)
- [DROP PROCEDURE](#)
- [DROP PROFILE](#)
- [DROP RESTORE POINT](#)
- [DROP ROLE](#)
- [DROP ROLLBACK SEGMENT](#)
- [DROP SEQUENCE](#)
- [DROP SYNONYM](#)

## DROP LIBRARY

### Purpose

Use the `DROP LIBRARY` statement to remove an external procedure library from the database.

 **See Also:**

[CREATE LIBRARY](#) for information on creating a library

### Prerequisites

You must have the `DROP ANY LIBRARY` system privilege.

## Syntax

*drop\_library ::=*

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### *library\_name*

Specify the name of the external procedure library being dropped.

## Examples

### Dropping a Library: Example

The following statement drops the `ext_lib` library:

```
DROP LIBRARY ext_lib;
```

# DROP LOCKDOWN PROFILE

## Purpose

Use the `DROP LOCKDOWN PROFILE` statement to remove a PDB lockdown profile from the database. A PDB that was assigned the dropped profile will continue to be assigned the profile, but will not be subject to the restrictions imposed by the dropped profile.

If the `PDB_LOCKDOWN` initialization parameter for a CDB, an application root, or a PDB has the value of the dropped lockdown profile, then the restrictions imposed by the dropped profile will be disabled when you drop it. However, the value of the `PDB_LOCKDOWN` initialization parameter will remain until you explicitly unset it.

### See Also:

- [CREATE LOCKDOWN PROFILE](#) and [ALTER LOCKDOWN PROFILE](#)
- *Oracle Database Security Guide* for more information on PDB lockdown profiles

## Prerequisites

- You must issue this statement from the CDB Root or the Application Root.

- You must have the `DROP LOCKDOWN PROFILE` system privilege in the container where you mean to issue the statement.

### Syntax

`drop_lockdown_profile ::=`

### Semantics

#### `profile_name`

Specify the name of the PDB lockdown profile to be dropped.

You can find the names of existing PDB lockdown profiles by querying the `DBA_LOCKDOWN_PROFILES` data dictionary view.

#### See Also:

*Oracle Database Reference* for more information on the `DBA_LOCKDOWN_PROFILES` data dictionary view and the `PDB_LOCKDOWN` initialization parameter

### Example

The following statement drops PDB lockdown profile `hr_prof`:

```
DROP LOCKDOWN PROFILE hr_prof;
```

## DROP MATERIALIZED VIEW

### Purpose

Use the `DROP MATERIALIZED VIEW` statement to remove an existing materialized view from the database.

When you drop a materialized view, Oracle Database does not place it in the recycle bin. Therefore, you cannot subsequently either purge or undrop the materialized view.

#### Note:

The keyword `SNAPSHOT` is supported in place of `MATERIALIZED VIEW` for backward compatibility.

**See Also:**

- [CREATE MATERIALIZED VIEW](#) for more information on the various types of materialized views
- [ALTER MATERIALIZED VIEW](#) for information on modifying a materialized view
- *Oracle Database Administrator's Guide* for information on materialized views in a replication environment
- *Oracle Database Data Warehousing Guide* for information on materialized views in a data warehousing environment

**Prerequisites**

The materialized view must be in your own schema or you must have the `DROP ANY MATERIALIZED VIEW` system privilege. You must also have the privileges to drop the internal table, views, and index that the database uses to maintain the materialized view data.

**See Also:**

[DROP TABLE](#) , [DROP VIEW](#) , and [DROP INDEX](#) for information on privileges required to drop objects that the database uses to maintain the materialized view

**Syntax**

***drop\_materialized\_view*::=**

**Semantics****IF EXISTS**

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

***schema***

Specify the schema containing the materialized view. If you omit `schema`, then Oracle Database assumes the materialized view is in your own schema.

***materialized\_view***

Specify the name of the existing materialized view to be dropped.

- If you drop a simple materialized view that is the least recently refreshed materialized view of a master table, then the database automatically purges from the master table materialized view log only the rows needed to refresh the dropped materialized view.
- If you drop a materialized view that was created on a prebuilt table, then the database drops the materialized view, and the prebuilt table reverts to its identity as a table.
- When you drop a master table, the database does not automatically drop materialized views based on the table. However, the database returns an error when it tries to refresh a materialized view based on a master table that has been dropped.
- If you drop a materialized view, then any compiled requests that were rewritten to use the materialized view will be invalidated and recompiled automatically. If the materialized view was prebuilt on a table, then the table is not dropped, but it can no longer be maintained by the materialized view refresh mechanism.

### PRESERVE TABLE Clause

This clause lets you retain the materialized view container table and its contents after the materialized view object is dropped. The resulting table has the same name as the dropped materialized view.

Oracle Database removes all metadata associated with the materialized view. However, indexes created on the container table automatically during creation of the materialized view are preserved, with one exception: the index created during the creation of a rowid materialized view is dropped. Also, if the materialized view has any nested table columns, then the storage tables for those columns are preserved, along with their metadata.

### Restriction on the PRESERVE TABLE Clause

This clause is not valid for materialized views that have been imported from releases earlier than Oracle9*i*, when these objects were called "snapshots".

### Examples

#### Dropping a Materialized View: Examples

The following statement drops the materialized view `emp_data` in the sample schema `hr`:

```
DROP MATERIALIZED VIEW emp_data;
```

The following statement drops the `sales_by_month_by_state` materialized view and the underlying table of the materialized view, unless the underlying table was registered in the CREATE MATERIALIZED VIEW statement with the ON PREBUILT TABLE clause:

```
DROP MATERIALIZED VIEW sales_by_month_by_state;
```

## DROP MATERIALIZED VIEW LOG

### Purpose

Use the `DROP MATERIALIZED VIEW LOG` statement to remove a materialized view log from the database.

**Note:**

The keyword `SNAPSHOT` is supported in place of `MATERIALIZED VIEW` for backward compatibility.

**See Also:**

- [CREATE MATERIALIZED VIEW](#) and [ALTER MATERIALIZED VIEW](#) for more information on materialized views
- [CREATE MATERIALIZED VIEW LOG](#) for information on materialized view logs
- *Oracle Database Administrator's Guide* for information on materialized views in a replication environment
- *Oracle Database Data Warehousing Guide* for information on materialized views in a data warehousing environment

**Prerequisites**

To drop a materialized view log, you must have the privileges needed to drop a table.

**See Also:**

[DROP TABLE](#)

**Syntax**

*drop\_materialized\_view\_log ::=*

**Semantics****IF EXISTS**

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

**schema**

Specify the schema containing the materialized view log and its master table. If you omit `schema`, then Oracle Database assumes the materialized view log and master table are in your own schema.

**table**

Specify the name of the master table associated with the materialized view log to be dropped.

After you drop a materialized view log that was created FOR FAST REFRESH, some materialized views based on the materialized view log master table can no longer be fast refreshed. These materialized views include rowid materialized views, primary key materialized views, and subquery materialized views.

 **See Also:**

*Oracle Database Data Warehousing Guide* for a description of these types of materialized views

After you drop a materialized view log that was created FOR SYNCHRONOUS REFRESH (a staging log), the materialized views based on the staging log master table can no longer be synchronous refreshed.

**Examples****Dropping a Materialized View Log: Example**

The following statement drops the materialized view log on the `oe.customers` master table:

```
DROP MATERIALIZED VIEW LOG ON customers;
```

## DROP MATERIALIZED ZONEMAP

**Purpose**

Use the `DROP MATERIALIZED ZONEMAP` statement to remove an existing zone map from the database.

**Prerequisites**

The zone map must be in your own schema or you must have the `DROP ANY MATERIALIZED VIEW` system privilege. You must also have the privileges to drop the internal table and indexes that the database uses to maintain the zone map data.

 **See Also:**

[DROP TABLE](#) and [DROP INDEX](#) for information on privileges required to drop objects that the database uses to maintain the zone map

**Syntax**

***drop\_materialized\_zonemap::=***

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### *schema*

Specify the schema containing the zone map. If you omit `schema`, then Oracle Database assumes the zone map is in your own schema.

### `zonemap_name`

Specify the name of the existing zone map to be dropped.

### Example

#### Dropping a Zone Map: Examples

The following statement drops the zone map `sales_zmap`:

```
DROP MATERIALIZED ZONEMAP sales_zmap;
```

## DROP MLE ENV

### Purpose

Drop an existing environment with `DROP MLE ENV`.

### Prerequisites

You must have the `DROP ANY MLE` privilege to drop an environment in schemas other than your own. No privilege is needed to drop an environment in your own schema.

### Syntax

## Semantics

Specify `IF EXISTS` to drop an existing MLE environment.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

 See Also:

- [CREATE MLE ENV](#)
- [ALTER MLE ENV](#)
- [CREATE MLE MODULE](#)

## DROP MLE MODULE

### Purpose

You can drop a previously deployed MLE module using `DROP MLE MODULE`.

### Syntax

### Semantics

Specify `IF EXISTS` to drop an existing MLE module.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

`schema` Specify the schema containing the MLE module. If you do not specify the schema, then Oracle Database assumes that the module is in your own schema.

`module_name` refers to the module name.

 See Also:

- [CREATE MLE MODULE](#)
- [ALTER MLE MODULE](#)

## DROP OPERATOR

### Purpose

Use the `DROP OPERATOR` statement to drop a user-defined operator.

**See Also:**

- [CREATE OPERATOR](#) and [ALTER OPERATOR](#) for information on creating and modifying operators
- "User-Defined Operators" and *Oracle Database Data Cartridge Developer's Guide* for more information on operators in general
- [ALTER INDEXTYPE](#) for information on dropping an operator of a user-defined indextype

**Prerequisites**

The operator must be in your schema or you must have the `DROP ANY OPERATOR` system privilege.

**Syntax**

*drop\_operator ::=*

**Semantics****IF EXISTS**

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

**schema**

Specify the schema containing the operator. If you omit `schema`, then Oracle Database assumes the operator is in your own schema.

**operator**

Specify the name of the operator to be dropped.

**FORCE**

Specify `FORCE` to drop the operator even if it is currently being referenced by one or more schema objects, such as indextypes, packages, functions, procedures, and so on. The database marks any such dependent objects `INVALID`. Without `FORCE`, you cannot drop an operator if any schema objects reference it.

**Examples****Dropping a User-Defined Operator: Example**

The following statement drops the operator `eq_op`:

```
DROP OPERATOR eq_op;
```

Because the `FORCE` clause is not specified, this operation will fail if any of the bindings of this operator are referenced by an indextype.

## DROP OUTLINE

### Purpose

#### Note:

- Stored outlines are deprecated. They are still supported for backward compatibility. However, Oracle recommends that you use SQL plan management instead. SQL plan management creates SQL plan baselines, which offer superior SQL performance stability compared with stored outlines.
- You can migrate existing stored outlines to SQL plan baselines by using the `MIGRATE_STORED_OUTLINE` function of the `DBMS_SPM` package or Enterprise Manager Cloud Control. When the migration is complete, the stored outlines are marked as migrated and can be removed. You can drop all migrated stored outlines on your system by using the `DROP_MIGRATED_STORED_OUTLINE` function of the `DBMS_SPM` package.
- **See Also:** *Oracle Database SQL Tuning Guide* for more information about SQL plan management and *Oracle Database PL/SQL Packages and Types Reference* for information about the `DBMS_SPM` package

Use the `DROP OUTLINE` statement to drop a stored outline.

#### See Also:

[CREATE OUTLINE](#) for information on creating an outline

### Prerequisites

To drop an outline, you must have the `DROP ANY OUTLINE` system privilege.

### Syntax

`drop_outline ::=`

### Semantics

#### `outline`

Specify the name of the outline to be dropped.

After the outline is dropped, if the SQL statement for which the stored outline was created is compiled, then the optimizer generates a new execution plan without the influence of the outline.

### Examples

#### Dropping an Outline: Example

The following statement drops the stored outline called salaries.

```
DROP OUTLINE salaries;
```

## DROP PACKAGE

### Purpose

Packages are defined using PL/SQL. Refer to *Oracle Database PL/SQL Language Reference* for complete information on creating, altering, and dropping packages.

Use the `DROP PACKAGE` statement to remove a stored package from the database. This statement drops the body and specification of a package.

#### Note:

Do not use this statement to remove a single object from a package. Instead, re-create the package without the object using the `CREATE PACKAGE` and `CREATE PACKAGE BODY` statements with the `OR REPLACE` clause.

### Prerequisites

The package must be in your own schema or you must have the `DROP ANY PROCEDURE` system privilege.

### Syntax

`drop_package ::=`

### Semantics

#### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

## BODY

Specify `BODY` to drop only the body of the package. If you omit this clause, then Oracle Database drops both the body and specification of the package.

When you drop only the body of a package but not its specification, the database does not invalidate dependent objects. However, you cannot call one of the procedures or stored functions declared in the package specification until you re-create the package body.

## *schema*

Specify the schema containing the package. If you omit `schema`, then the database assumes the package is in your own schema.

## *package*

Specify the name of the package to be dropped.

Oracle Database invalidates any local objects that depend on the package specification. If you subsequently reference one of these objects, then the database tries to recompile the object and returns an error if you have not re-created the dropped package.

If any statistics types are associated with the package, then the database disassociates the statistics types with the `FORCE` clause and drops any user-defined statistics collected with the statistics types.

### See Also:

[ASSOCIATE STATISTICS](#) and [DISASSOCIATE STATISTICS](#)

## Examples

### Dropping a Package: Example

The following statement drops the specification and body of the `emp_mgmt` package, invalidating all objects that depend on the specification. See *Oracle Database PL/SQL Language Reference* for the example that creates this package.

```
DROP PACKAGE emp_mgmt;
```

# DROP PLUGGABLE DATABASE

## Purpose

Use the `DROP PLUGGABLE DATABASE` statement to drop a pluggable database (PDB). The PDB can be a traditional PDB, an application container, an application seed, or an application PDB.

When you drop a PDB, the control file of the multitenant container database (CDB) is modified to remove all references to the dropped PDB and its data files. Archived logs and backups associated with the dropped PDB are not deleted. You can delete them using Oracle Recovery Manager (RMAN), or you can retain them in case you subsequently want to perform point-in-time recovery of the PDB.

**Caution:**

You cannot roll back a `DROP PLUGGABLE DATABASE` statement.

**Prerequisites**

You must be connected to a CDB.

To drop a traditional PDB or an application container, the current container must be the root, you must be authenticated AS SYSDBA or AS SYSOPER, and the SYSDBA or SYSOPER privilege must be either granted to you commonly, or granted to you locally in the root and locally in traditional PDB or application container you want to drop. The application container must be empty, that is, it must not contain an application seed or any application PDBs.

To drop an application seed, the current container must be the root or the application root, you must be authenticated AS SYSDBA or AS SYSOPER, and the SYSDBA or SYSOPER privilege must be either granted to you commonly, or granted to you locally in the root or application root.

To drop an application PDB, the current container must be the root or the application root, you must be authenticated AS SYSDBA or AS SYSOPER, and the SYSDBA or SYSOPER privilege must be either granted to you commonly, or granted to you locally in the root or application root, and locally in the application PDB you want to drop.

To specify `KEEP DATAFILES` (the default), the PDB you want to drop must be unplugged.

To specify `INCLUDING DATAFILES`, the PDB you want to drop must be in mounted mode or it must be unplugged.

**Syntax**

`drop_pluggable_database ::=`

**Semantics*****pdb\_name***

Specify the name of the PDB you want to drop. You cannot drop the seed (`PDB$SEED`). However, you can drop an application seed.

**KEEP DATAFILES**

Specify `KEEP DATAFILES` to retain the data files associated with the PDB after the PDB is dropped. The temp file for the PDB is deleted because it is no longer needed. This is the default.

Keeping data files may be useful in scenarios where a PDB that is unplugged from one CDB is plugged into another CDB, with both CDBs sharing storage devices.

## INCLUDING DATAFILES

Specify `INCLUDING DATAFILES` to delete the data files associated with the PDB being dropped. The temp file for the PDB is also deleted.

### Restriction on Dropping SNAPSHOT COPY PDBs

If a PDB was created with the `SNAPSHOT COPY` clause, then you must specify `INCLUDING DATAFILES` when you drop the PDB.

### Examples

#### Dropping a PDB: Example

The following statement drops the PDB `pdb1` and its associated data files:

```
DROP PLUGGABLE DATABASE pdb1
    INCLUDING DATAFILES;
```

# DROP PMEM FILESTORE

### Purpose

You can drop a PMEM file store with this command.

### Syntax

`drop_pmem_filestore ::=`

### Semantics

#### INCLUDING CONTENTS

Specify `INCLUDING CONTENTS` to confirm that Oracle should remove all the files in the PMEM file store.

#### EXCLUDING CONTENTS

Specify `EXCLUDING CONTENTS` to ensure that Oracle drops the PMEM file store only when the file store is empty.

#### FORCE

Specify `FORCE` along with `INCLUDING CONTENTS` if you suspect that the file store is corrupt.

Note that this option does not check if the file store has content in it prior to deleting it.

If you specify neither `INCLUDING CONTENTS` nor `EXCLUDING CONTENTS`, you must ensure that the file store is empty. `EXCLUDING CONTENTS` is the default behavior.

**Example**

```
DROP PMEM FILESTORE cloud_db_1 EXCLUDING CONTENTS
```

# DROP PROCEDURE

**Purpose**

Procedures are defined using PL/SQL. Refer to *Oracle Database PL/SQL Language Reference* for complete information on creating, altering, and dropping procedures.

Use the `DROP PROCEDURE` statement to remove a standalone stored procedure from the database. Do not use this statement to remove a procedure that is part of a package. Instead, either drop the entire package using the `DROP PACKAGE` statement, or redefine the package without the procedure using the `CREATE PACKAGE` statement with the `OR REPLACE` clause.

**Prerequisites**

The procedure must be in your own schema or you must have the `DROP ANY PROCEDURE` system privilege.

**Syntax**

*drop\_procedure*::=

**Semantics****IF EXISTS**

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

**schema**

Specify the schema containing the procedure. If you omit *schema*, then Oracle Database assumes the procedure is in your own schema.

**procedure**

Specify the name of the procedure to be dropped.

When you drop a procedure, Oracle Database invalidates any local objects that depend upon the dropped procedure. If you subsequently reference one of these objects, then the database tries to recompile the object and returns an error message if you have not re-created the dropped procedure.

**Examples****Dropping a Procedure: Example**

The following statement drops the procedure `remove_emp` owned by the user `hr` and invalidates all objects that depend upon `remove_emp`:

```
DROP PROCEDURE hr.remove_emp;
```

## DROP PROFILE

### Purpose

Use the `DROP PROFILE` statement to remove a profile from the database. You can drop any profile except the `DEFAULT` profile.

#### See Also:

[CREATE PROFILE](#) and [ALTER PROFILE](#) on creating and modifying a profile

### Prerequisites

You must have the `DROP PROFILE` system privilege.

### Syntax

*drop\_profile ::=*

### Semantics

#### *profile*

Specify the name of the profile to be dropped.

#### CASCADE

Specify `CASCADE` to deassign the profile from any users to whom it is assigned. Oracle Database automatically assigns the `DEFAULT` profile to such users. You must specify this clause to drop a profile that is currently assigned to users.

### Examples

#### Dropping a Profile: Example

The following statement drops the profile `app_user`, which was created in "Creating a Profile: Example". Oracle Database drops the profile `app_user` and assigns the `DEFAULT` profile to any users currently assigned the `app_user` profile:

```
DROP PROFILE app_user CASCADE;
```

# DROP PROPERTY GRAPH

## Purpose

You can drop property graphs with `DROP PROPERTY GRAPH`.

## Prerequisites

Like tables and views, you can drop a property graph in your own schema. To drop a property graph in any schema except `SYS` and `AUDSYS`, you must have the `DROP ANY PROPERTY GRAPH` privilege.

## Syntax

`drop_property_graph ::=`

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing property graph.

If you specify `IF NOT EXISTS` with `DROP`, the command fails with the error message:  
Incorrect IF EXISTS clause for ALTER/DROP statement.

# DROP RESTORE POINT

## Purpose

Use the `DROP RESTORE POINT` statement to remove a normal restore point or a guaranteed restore point from the database.

- You need not drop normal restore points. The database automatically drops the oldest restore points when necessary, as described in the semantics for `restore_point`. However, you can drop a normal restore point if you want to reuse the name.
- Guaranteed restore points are not dropped automatically. Therefore, if you want to remove a guaranteed restore point from the database, then you must do so explicitly using this statement.

### See Also:

[CREATE RESTORE POINT](#) , [FLASHBACK DATABASE](#), and [FLASHBACK TABLE](#) for information on creating and using restore points

## Prerequisites

To drop a normal restore point, you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSBACKUP, or SYSDG system privilege.

To drop a guaranteed restore point, you must fulfill one of the following conditions:

- You must connect AS SYSDBA, or AS SYSBACKUP, or AS SYSDG.
- You must have been granted the SYSDBA privilege, and be using a multitenant database.
- You must be running as user SYS, and be using a multitenant database.

You can drop a restore point when connected to a multitenant container database (CDB) as follows:

- To drop a normal CDB restore point, the current container must be the root and you must have the SELECT ANY DICTIONARY or FLASHBACK ANY TABLE system privilege, either granted commonly or granted locally in the root, or the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly.
- To drop a guaranteed CDB restore point, the current container must be the root and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege granted commonly.
- To drop a normal PDB restore point, the current container must be the root and you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly, or the current container must be the PDB in which you want to create the restore point and you must have the SELECT ANY DICTIONARY, FLASHBACK ANY TABLE, SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.
- To drop a guaranteed PDB restore point, the current container must be the root and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly, or the current container must be the PDB in which you want to create the restore point and you must have the SYSDBA, SYSBACKUP, or SYSDG system privilege, granted commonly or granted locally in that PDB.

## Syntax

*drop\_restore\_point::=*

## Semantics

### *restore\_point*

Specify the name of the restore point you want to drop.

### FOR PLUGGABLE DATABASE

This clause enables you to drop a PDB restore point when you are connected to the root. For *pdb\_name*, specify the name of the PDB that contains the restore point you want to drop.

If you are connected to the PDB from which you want to drop the restore point, then it is not necessary to specify this clause. However, if you specify this clause, then you must specify the name of the PDB to which you are connected.

### Examples

#### Dropping a Restore Point: Example

The following example drops the `good_data` restore point, which was created in "Creating and Using a Restore Point: Example":

```
DROP RESTORE POINT good_data;
```

## DROP ROLE

### Purpose

Use the `DROP ROLE` statement to remove a role from the database. When you drop a role, Oracle Database revokes it from all users and roles to whom it has been granted and removes it from the database. User sessions in which the role is already enabled are not affected. However, no new user session can enable the role after it is dropped.

#### See Also:

- [CREATE ROLE](#) and [ALTER ROLE](#) for information on creating roles and changing the authorization needed to enable a role
- [SET ROLE](#) for information on disabling roles for the current session

### Prerequisites

You must have been granted the role with the `ADMIN OPTION` or you must have the `DROP ANY ROLE` system privilege.

### Syntax

*drop\_role ::=*

### Semantics

#### *role*

Specify the name of the role to be dropped.

### Examples

#### Dropping a Role: Example

To drop the role `dw_manager`, which was created in "Creating a Role: Example", issue the following statement:

```
DROP ROLE dw_manager;
```

# DROP ROLLBACK SEGMENT

## Purpose

Use the `DROP ROLLBACK SEGMENT` to remove a rollback segment from the database. When you drop a rollback segment, all space allocated to the rollback segment returns to the tablespace.

### Note:

If your database is running in automatic undo mode, then this is the only valid operation on rollback segments. In that mode, you cannot create or alter a rollback segment.

## Prerequisites

You must have the `DROP ROLLBACK SEGMENT` system privilege, and the rollback segment must be offline.

## Syntax

*drop\_rollback\_segment*::=

## Semantics

### *rollback\_segment*

Specify the name the rollback segment to be dropped.

## Restrictions on Dropping Rollback Segments

This statement is subject to the following restrictions:

- You can drop a rollback segment only if it is offline. To determine whether a rollback segment is offline, query the data dictionary view `DBA_ROLLBACK_SEGS`. Offline rollback segments have the value `AVAILABLE` in the `STATUS` column. You can take a rollback segment offline with the `OFFLINE` clause of the `ALTER ROLLBACK SEGMENT` statement.
- You cannot drop the `SYSTEM` rollback segment.

## Examples

### Dropping a Rollback Segment: Example

The following syntax drops the rollback segment created in "[Creating a Rollback Segment: Example](#)":

```
DROP ROLLBACK SEGMENT rbs_one;
```

# DROP SEQUENCE

## Purpose

Use the `DROP SEQUENCE` statement to remove a sequence from the database.

You can also use this statement to restart a sequence by dropping and then re-creating it. For example, if you have a sequence with a current value of 150 and you would like to restart the sequence with a value of 27, then you can drop the sequence and then re-create it with the same name and a `START WITH` value of 27.

### See Also:

[CREATE SEQUENCE](#) and [ALTER SEQUENCE](#) for more information on creating and modifying a sequence

## Prerequisites

The sequence must be in your own schema or you must have the `DROP ANY SEQUENCE` system privilege.

## Syntax

`drop_sequence ::=`

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### *schema*

Specify the schema containing the sequence. If you omit `schema`, then Oracle Database assumes the sequence is in your own schema.

### `sequence_name`

Specify the name of the sequence to be dropped.

## Examples

### Dropping a Sequence: Example

The following statement drops the sequence `customers_seq` owned by the user `oe`, which was created in "[Creating a Sequence: Example](#)". To issue this statement, you must either be connected as user `oe` or have the `DROP ANY SEQUENCE` system privilege:

```
DROP SEQUENCE oe.customers_seq;
```

## DROP SYNONYM

### Purpose

Use the `DROP SYNONYM` statement to remove a synonym from the database or to change the definition of a synonym by dropping and re-creating it.

#### See Also:

[CREATE SYNONYM](#) for more information on synonyms

### Prerequisites

To drop a private synonym, either the synonym must be in your own schema or you must have the `DROP ANY SYNONYM` system privilege.

To drop a `PUBLIC` synonym, you must have the `DROP PUBLIC SYNONYM` system privilege.

### Syntax

*drop\_synonym ::=*

*drop\_synonym ::=*

### Semantics

#### PUBLIC

You must specify `PUBLIC` to drop a public synonym. You cannot specify `schema` if you have specified `PUBLIC`.

#### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

#### *schema*

Specify the schema containing the synonym. If you omit `schema`, then Oracle Database assumes the synonym is in your own schema.

### ***synonym***

Specify the name of the synonym to be dropped.

If you drop a synonym for the master table of a materialized view, and if the defining query of the materialized view specified the synonym rather than the actual table name, then Oracle Database marks the materialized view unusable.

If an object type synonym has any dependent tables or user-defined types, then you cannot drop the synonym unless you also specify **FORCE**.

### **FORCE**

Specify **FORCE** to drop the synonym even if it has dependent tables or user-defined types.

#### **Note:**

Oracle does not recommend that you specify **FORCE** to drop object type synonyms with dependencies. This operation can result in invalidation of other user-defined types or marking **UNUSED** the table columns that depend on the synonym. For information about type dependencies, see *Oracle Database Object-Relational Developer's Guide*.

## **Examples**

### **Dropping a Synonym: Example**

To drop the public synonym named `customers`, which was created in "[Oracle Database Resolution of Synonyms: Example](#)", issue the following statement:

```
DROP PUBLIC SYNONYM customers;
```

# SQL Statements: DROP TABLE to LOCK TABLE

This chapter contains the following SQL statements:

- [DROP TABLE](#)
- [DROP TABLESPACE](#)
- [DROP TABLESPACE SET](#)
- [DROP TRIGGER](#)
- [DROP TYPE](#)
- [DROP TYPE BODY](#)
- [DROP USER](#)
- [DROP VIEW](#)
- [EXPLAIN PLAN](#)
- [FLASHBACK DATABASE](#)
- [FLASHBACK TABLE](#)
- [GRANT](#)
- [INSERT](#)
- [LOCK TABLE](#)

## DROP TABLE

### Purpose

Use the `DROP TABLE` statement to move a table or object table to the recycle bin or to remove the table and all its data from the database entirely.

#### Note:

Unless you specify the `PURGE` clause, the `DROP TABLE` statement does not result in space being released back to the tablespace for use by other objects, and the space continues to count toward the user's space quota.

For an external table, this statement removes only the table metadata in the database. It has no affect on the actual data, which resides outside of the database.

When you drop a table that is part of a cluster, the table is moved to the recycle bin. However, if you subsequently drop the cluster, then the table is purged from the recycle bin and can no longer be recovered with a `FLASHBACK TABLE` operation.

Dropping a table invalidates dependent objects and removes object privileges on the table. If you want to re-create the table, then you must regrant object privileges on the table, re-create the indexes, integrity constraints, and triggers for the table, and respecify its storage parameters. Truncating has none of these effects. Therefore, removing rows with the `TRUNCATE` statement can be more efficient than dropping and re-creating a table.

### See Also:

- [CREATE TABLE](#) and [ALTER TABLE](#) for information on creating and modifying tables
- [TRUNCATE TABLE](#) and [DELETE](#) for information on removing data from a table
- [FLASHBACK TABLE](#) for information on retrieving a dropped table from the recycle bin

### Prerequisites

The table must be in your own schema or you must have the `DROP ANY TABLE` system privilege.

You can perform DDL operations (such as `ALTER TABLE`, `DROP TABLE`, `CREATE INDEX`) on a temporary table only when no session is bound to it. A session becomes bound to a temporary table by performing an `INSERT` operation on the table. A session becomes unbound to the temporary table by issuing a `TRUNCATE` statement or at session termination, or, for a transaction-specific temporary table, by issuing a `COMMIT` or `ROLLBACK` statement.

### Dropping Private Temporary Tables

You can drop a private temporary table using the existing `DROP TABLE` command. Dropping a private temporary table will not commit an existing transaction. This applies to both transaction-specific and session-specific private temporary tables. Note that a dropped private temporary table will not go into the `RECYCLEBIN`.

### Dropping Blockchain and Immutable Tables

Use the `DROP TABLE` statement to drop a blockchain or immutable table. It is recommended that you include the `PURGE` option while dropping these tables. Dropping a blockchain or immutable table removes its definition from the data dictionary, deletes all its rows, and deletes any indexes and triggers defined on the table.

The blockchain or immutable table must be contained in your schema, or you must have the `DROP ANY TABLE` system privilege.

A blockchain or immutable table can be dropped only after it has not been modified for a period of time that is defined by its retention period.

An empty blockchain or immutable table can be dropped regardless of its retention period.

## Syntax

*drop\_table ::=*

## Semantics

### IF EXISTS

Specifying `IF EXISTS` drops the table if it exists.

Using `IF NOT EXISTS` with `DROP TABLE` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### *schema*

Specify the schema containing the table. If you omit *schema*, then Oracle Database assumes the table is in your own schema.

### *table*

Specify the name of the table to be dropped. Oracle Database automatically performs the following operations:

- All rows from the table are dropped.
- All table indexes and domain indexes are dropped, as well as any triggers defined on the table, regardless of who created them or whose schema contains them. If *table* is partitioned, then any corresponding local index partitions are also dropped.
- All the storage tables of nested tables and LOBs of *table* are dropped.
- When you drop a range-, hash-, or list-partitioned table, then the database drops all the table partitions. If you drop a composite-partitioned table, then all the partitions and subpartitions are also dropped.
- When you drop a partitioned table with the `PURGE` keyword, the statement executes as a series of subtransactions, each of which drops a subset of partitions or subpartitions and their metadata. This division of the drop operation into subtransactions optimizes the processing of internal system resource consumption (for example, the library cache), especially for the dropping of very large partitioned tables. As soon as the first subtransaction commits, the table is marked `UNUSABLE`. If any of the subtransactions fails, then the only operation allowed on the table is another `DROP TABLE ... PURGE` statement. Such a statement will resume work from where the previous `DROP TABLE` statement failed, assuming that you have corrected any errors that the previous operation encountered.

You can list the tables marked `UNUSABLE` by such a drop operation by querying the `status` column of the `*_TABLES`, `*_PART_TABLES`, `*_ALL_TABLES`, or `*_OBJECT_TABLES` data dictionary views, as appropriate.

 **See Also:**

*Oracle Database VLDB and Partitioning Guide* for more information on dropping partitioned tables.

- For an index-organized table, any mapping tables defined on the index-organized table are dropped.
- For a domain index, the appropriate drop routines are invoked. Refer to *Oracle Database Data Cartridge Developer's Guide* for more information on these routines.
- If any statistics types are associated with the table, then the database disassociates the statistics types with the `FORCE` clause and removes any user-defined statistics collected with the statistics type.

 **See Also:**

[ASSOCIATE STATISTICS](#) and [DISASSOCIATE STATISTICS](#) for more information on statistics type associations

- If the table is not part of a cluster, then the database returns all data blocks allocated to the table and its indexes to the tablespaces containing the table and its indexes.

To drop a cluster and all its tables, use the `DROP CLUSTER` statement with the `INCLUDING TABLES` clause to avoid dropping each table individually. See [DROP CLUSTER](#).

- If the table is a base table for a view, a container or master table of a materialized view, or if it is referenced in a stored procedure, function, or package, then the database invalidates these dependent objects but does not drop them. You cannot use these objects unless you re-create the table or drop and re-create the objects so that they no longer depend on the table.

If you choose to re-create the table, then it must contain all the columns selected by the subqueries originally used to define the materialized views and all the columns referenced in the stored procedures, functions, or packages. Any users previously granted object privileges on the views, stored procedures, functions, or packages need not be regranted these privileges.

If the table is a master table for a materialized view, then the materialized view can still be queried, but it cannot be refreshed unless the table is re-created so that it contains all the columns selected by the defining query of the materialized view.

If the table has a materialized view log, then the database drops this log and any other direct-path `INSERT` refresh information associated with the table.

### Restrictions on Dropping Tables

- You cannot directly drop the storage table of a nested table. Instead, you must drop the nested table column using the `ALTER TABLE ... DROP COLUMN` clause.
- You cannot drop the parent table of a reference-partitioned table. You must first drop all reference-partitioned child tables.

- You cannot drop a table that uses a flashback data archive for historical tracking. You must first disable the table's use of the flashback archive.

### CASCADE CONSTRAINTS

Specify `CASCADE CONSTRAINTS` to drop all referential integrity constraints that refer to primary and unique keys in the dropped table. If you omit this clause, and such referential integrity constraints exist, then the database returns an error and does not drop the table.

### PURGE

Specify `PURGE` if you want to drop the table and release the space associated with it in a single step. If you specify `PURGE`, then the database does not place the table and its dependent objects into the recycle bin.

 **Note:**

You cannot roll back a `DROP TABLE` statement with the `PURGE` clause, nor can you recover the table if you have dropped it with the `PURGE` clause.

Using this clause is equivalent to first dropping the table and then purging it from the recycle bin. This clause lets you save one step in the process. It also provides enhanced security if you want to prevent sensitive material from appearing in the recycle bin.

 **See Also:**

*Oracle Database Administrator's Guide* for information on the recycle bin and naming conventions for objects in the recycle bin

### Examples

#### Dropping a Table: Example

The following statement drops the `oe.list_customers` table created in "[List Partitioning Example](#)".

```
DROP TABLE list_customers PURGE;
```

## DROP TABLESPACE

### Purpose

Use the `DROP TABLESPACE` statement to remove a tablespace from the database.

When you drop a tablespace, Oracle Database does not place it in the recycle bin. Therefore, you cannot subsequently either purge or undrop the tablespace.

**See Also:**

[CREATE TABLESPACE](#) and [ALTER TABLESPACE](#) for information on creating and modifying a tablespace

**Prerequisites**

You must have the `DROP TABLESPACE` system privilege. You cannot drop a tablespace if it contains any rollback segments holding active transactions.

**Syntax**

`drop_tablespace ::=`

**IF NOT EXISTS**

Specify `IF EXISTS` to drop an existing tablespace.

Specifying `IF NOT EXISTS` with `ALTER` results in error: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

**Semantics****tablespace**

Specify the name of the tablespace to be dropped, including those of shadow tablespaces, that store lost write protection updates.

You can drop a tablespace regardless of whether it is online or offline. Oracle recommends that you take the tablespace offline before dropping it to ensure that no SQL statements in currently running transactions access any of the objects in the tablespace.

You cannot drop the `SYSTEM` tablespace. You can drop the `SYSAUX` tablespace only if you have the `SYSDBA` system privilege and you have started the database in `UPGRADE` mode.

You may want to alert any users who have been assigned the tablespace as either a default or temporary tablespace. After the tablespace has been dropped, these users cannot allocate space for objects or sort areas in the tablespace. You can reassign users new default and temporary tablespaces with the `ALTER USER` statement.

Any objects that were previously dropped from the tablespace and moved to the recycle bin are purged from the recycle bin. Oracle Database removes from the data dictionary all metadata about the tablespace and all data files and temp files in the tablespace. The database also automatically drops from the operating system any Oracle-managed data files and temp files in the tablespace. Other data files and temp files are not removed from the operating system unless you specify `INCLUDING CONTENTS AND DATAFILES`.

You cannot use this statement to drop a tablespace group. However, if `tablespace` is the only tablespace in a tablespace group, then Oracle Database removes the tablespace group from the data dictionary as well.

### Restrictions on Dropping Tablespaces

Dropping tablespaces is subject to the following restrictions:

- You cannot drop a tablespace that contains a domain index or any objects created by a domain index.
- You cannot drop an undo tablespace if it is being used by any instance or if it contains any undo data needed to roll back uncommitted transactions.
- You cannot drop a tablespace that has been designated as the default tablespace for the database. You must first reassign another tablespace as the default tablespace and then drop the old default tablespace.
- You cannot drop a temporary tablespace if it is part of the database default temporary tablespace group. You must first remove the tablespace from the database default temporary tablespace group and then drop it.
- You cannot drop a temporary tablespace if it contains segments that are in use by existing sessions. In this case, no error is raised. The database waits until there are no segments in use by existing sessions and then drops the tablespace.
- You cannot drop a tablespace, even with the `INCLUDING CONTENTS` and `CASCADE CONSTRAINTS` clauses, if doing so would disable a primary key or unique constraint in another tablespace. For example, if the tablespace being dropped contains a primary key index, but the primary key column itself is in a different tablespace, then you cannot drop the tablespace until you have manually disabled the primary key constraint in the other tablespace.

#### See Also:

*Oracle Database Data Cartridge Developer's Guide* and *Oracle Database Concepts* for more information on domain indexes

### { DROP | KEEP } QUOTA

Specify `DROP QUOTA` to drop all user quotas for the tablespace. Specify `KEEP QUOTA` to retain all user quotas for the tablespace. The default is `KEEP QUOTA`.

You can view all user quotas for a tablespace by querying the `DBA_TS_QUOTAS` data dictionary view.

### INCLUDING CONTENTS

Specify `INCLUDING CONTENTS` to drop all the contents of the tablespace, including those of shadow tablespaces that store lost write protection updates. You must specify this clause to

drop a tablespace that contains any database objects. If you omit this clause, and the tablespace is not empty, then the database returns an error and does not drop the tablespace.

DROP TABLESPACE fails, even if you specify `INCLUDING CONTENTS`, if the tablespace contains some, but not all, of the partitions or subpartitions of a single table. If all the partitions or subpartitions of a partitioned table reside in `tablespace`, then `DROP TABLESPACE ... INCLUDING CONTENTS` drops `tablespace`, as well as any associated index segments, LOB data and index segments, and nested table data and index segments of `table` in other tablespace(s).

For a partitioned index-organized table, if all the primary key index segments are in this tablespace, then this clause will also drop any overflow segments that exist in other tablespaces, as well as any associated mapping table in other tablespaces. If some of the primary key index segments are *not* in this tablespace, then the statement will fail. In that case, before you can drop the tablespace, you must use `ALTER TABLE ... MOVE PARTITION` to move those primary key index segments into this tablespace, drop the partitions whose overflow data segments are not in this tablespace, and drop the partitioned index-organized table.

If the tablespace contains a master table of a materialized view, then the database invalidates the materialized view.

If the tablespace contains a materialized view log, then the database drops the log and any other direct-path `INSERT` refresh information associated with the table.

### AND DATAFILES

When you specify `INCLUDING CONTENTS`, the `AND DATAFILES` clause lets you instruct the database to delete the associated operating system files as well. Oracle Database writes a message to the alert log for each operating system file deleted. This clause is not needed for Oracle Managed Files, because they are removed from the system even if you do not specify `AND DATAFILES`.

### KEEP DATAFILES

When you specify `INCLUDING CONTENTS`, the `KEEP DATAFILES` clause lets you instruct the database to leave untouched the associated operating system files, including Oracle Managed Files. You must specify this clause if you are using Oracle Managed Files and you do not want the associated operating system files removed by the `INCLUDING CONTENTS` clause.

### CASCADE CONSTRAINTS

Specify `CASCADE CONSTRAINTS` to drop all referential integrity constraints from tables outside `tablespace` that refer to primary and unique keys of tables inside `tablespace`. If you omit this clause and such referential integrity constraints exist, then Oracle Database returns an error and does not drop the tablespace.

### Examples

#### Dropping a Tablespace: Example

The following statement drops the `tbs_01` tablespace and drops all referential integrity constraints that refer to primary and unique keys inside `tbs_01`:

```
DROP TABLESPACE tbs_01
  INCLUDING CONTENTS
  CASCADE CONSTRAINTS;
```

### Dropping a Shadow Tablespace: Example

The following statement tries to move the tracked data in the shadow tablespace to another shadow tablespace. This only works if there are shadow tablespaces in the PDB with enough free space.

```
DROP TABLESPACE <shadow_tablespace_name>
```

The following statement drops the shadow tablespace and all its contents. All the tracking data is lost.

### Dropping Shadow Tablespace Including Contents: Example

```
DROP TABLESPACE <shadow_tablespace_name>
    INCLUDING CONTENTS
```

### Deleting Operating System Files: Example

The following example drops the `tbs_02` tablespace and deletes all associated operating system data files:

```
DROP TABLESPACE tbs_02
    INCLUDING CONTENTS AND DATAFILES;
```

## DROP TABLESPACE SET

### Note:

This SQL statement is valid only if you are using Oracle Sharding. For more information on Oracle Sharding, refer to *Oracle Database Administrator's Guide*.

### Purpose

Use the `DROP TABLESPACE SET` statement to drop a tablespace set from a shardgroup.

When you drop a tablespace set, Oracle Database does not place it in the recycle bin. Therefore, you cannot subsequently either purge or undrop the tablespace set.

### See Also:

[CREATE TABLESPACE SET](#) and [ALTER TABLESPACE SET](#)

### Prerequisites

You must be connected to a shard catalog database as an SDB user.

You must have the `DROP TABLESPACE` system privilege. You cannot drop a tablespace set if its tablespaces contain any rollback segments holding active transactions.

## Syntax

*drop\_tablespace\_set::=*

## Semantics

### *tablespace\_set*

Specify the name of the tablespace set to be dropped.

### INCLUDING CONTENTS

This clause lets you specify how the database manages objects and datafiles associated with the tablespaces in the tablespace set during the drop operation. The INCLUDING CONTENTS clause has the same semantics here as for the `DROP TABLESPACE` statement. See [INCLUDING CONTENTS](#) for the full semantics of this clause.

## Examples

### Dropping a Tablespace Set: Example

The following statement drops the tablespace set `ts1`:

```
DROP TABLESPACE SET ts1;
```

# DROP TRIGGER

## Purpose

Triggers are defined using PL/SQL. Refer to *Oracle Database PL/SQL Language Reference* for complete information on creating, altering, and dropping triggers.

Use the `DROP TRIGGER` statement to remove a database trigger from the database.

### See Also:

[CREATE TRIGGER](#) and [ALTER TRIGGER](#)

## Prerequisites

The trigger must be in your own schema or you must have the `DROP ANY TRIGGER` system privilege. To drop a trigger on `DATABASE` in another user's schema, you must also have the `ADMINISTER DATABASE TRIGGER` system privilege.

## Syntax

*drop\_trigger ::=*

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### schema

Specify the schema containing the trigger. If you omit `schema`, then Oracle Database assumes the trigger is in your own schema.

### trigger

Specify the name of the trigger to be dropped. Oracle Database removes it from the database and does not fire it again.

## Examples

### Dropping a Trigger: Example

The following statement drops the `salary_check` trigger in the schema `hr`:

```
DROP TRIGGER hr.salary_check;
```

# DROP TYPE

## Purpose

Object types are defined using PL/SQL. Refer to *Oracle Database PL/SQL Language Reference* for complete information on creating, altering, and dropping object types.

Use the `DROP TYPE` statement to drop the specification and body of an object type, a varray, or a nested table type.

## Prerequisites

The object type, varray, or nested table type must be in your own schema or you must have the `DROP ANY TYPE` system privilege.

## Syntax

*drop\_type ::=*

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### Semantics

#### *schema*

Specify the schema containing the type. If you omit *schema*, then Oracle Database assumes the type is in your own schema.

#### *type\_name*

Specify the name of the object, varray, or nested table type to be dropped. You can drop only types with no type or table dependencies. This includes tables in the recycle bin.

When you drop a type, any dependent objects such as subtypes are not placed in the recycle bin and any former dependent objects in the recycle bin are purged.

If *type\_name* is a supertype, then this statement will fail unless you also specify `FORCE`. If you specify `FORCE`, then the database invalidates all subtypes depending on this supertype.

If *type\_name* is a statistics type, then this statement will fail unless you also specify `FORCE`. If you specify `FORCE`, then the database first disassociates all objects that are associated with *type\_name* and then drops *type\_name*.

#### See Also:

[ASSOCIATE STATISTICS](#) and [DISASSOCIATE STATISTICS](#) for more information on statistics types

If *type\_name* is an object type that has been associated with a statistics type, then the database first attempts to disassociate *type\_name* from the statistics type and then drops *type\_name*. However, if statistics have been collected using the statistics type, then the database will be unable to disassociate *type\_name* from the statistics type, and this statement will fail.

If `type_name` is an implementation type for an indextype, then the indextype will be marked INVALID.

If `type_name` has a public synonym defined on it, then the database will also drop the synonym.

Unless you specify FORCE, you can drop only object types, nested tables, or varray types that are standalone schema objects with no dependencies. This is the default behavior.

 **See Also:**

[CREATE INDEXTYPE](#)

### FORCE

Specify FORCE to drop the type even if it has dependent database objects. Oracle Database marks UNUSED all columns dependent on the type to be dropped, and those columns become inaccessible.

 **Note:**

Oracle does not recommend that you specify FORCE to drop object types with dependencies. These include dependent tables in the recycle bin. This operation is not recoverable and could cause the data in the dependent tables or columns to become inaccessible.

Refer to *Managing Tables*.

### VALIDATE

If you specify VALIDATE when dropping a type, then Oracle Database checks for stored instances of this type within substitutable columns of any of its supertypes. If no such instances are found, then the database completes the drop operation.

This clause is meaningful only for subtypes. Oracle recommends the use of this option to safely drop subtypes that do not have any explicit type or table dependencies.

### Examples

#### Dropping an Object Type: Example

The following statement removes object type `person_t`. See *Oracle Database PL/SQL Language Reference* for the example that creates this object type. Any columns that are dependent on `person_t` are marked UNUSED and become inaccessible.

```
DROP TYPE person_t FORCE;
```

# DROP TYPE BODY

## Purpose

Object types are defined using PL/SQL. Refer to *Oracle Database PL/SQL Language Reference* for complete information on creating, altering, and dropping object types.

Use the `DROP TYPE BODY` statement to drop the body of an object type, varray, or nested table type. When you drop a type body, the object type specification still exists, and you can re-create the type body. Prior to re-creating the body, you can still use the object type, although you cannot call the member functions.

## Prerequisites

The object type body must be in your own schema or you must have the `DROP ANY TYPE` system privilege.

## Syntax

`drop_type_body ::=`

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### schema

Specify the schema containing the object type. If you omit `schema`, then Oracle Database assumes the object type is in your own schema.

### type\_name

Specify the name of the object type body to be dropped.

### Restriction on Dropping Type Bodies

You can drop a type body only if it has no type or table dependencies.

## Examples

### Dropping an Object Type Body: Example

The following statement removes object type body `data_typ1`. See *Oracle Database PL/SQL Language Reference* for the example that creates this object type.

```
DROP TYPE BODY data_typ1;
```

# DROP USER

## Purpose

Use the `DROP USER` statement to remove a database user and optionally remove the user's objects.

In an Oracle Automatic Storage Management (Oracle ASM) cluster, a user authenticated `AS SYSASM` can use this clause to remove a user from the password file that is local to the Oracle ASM instance of the current node.

When you drop a user, Oracle Database also purges all of that user's schema objects from the recycle bin.

### Note:

Do not attempt to drop the users `SYS` or `SYSTEM`. Doing so will corrupt your database.

### See Also:

[CREATE USER](#) and [ALTER USER](#) for information on creating and modifying a user

## Prerequisites

You must have the `DROP USER` system privilege. In an Oracle ASM cluster, you must be authenticated `AS SYSASM`.

## Syntax

`drop_user ::=`

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### **user**

Specify the user to be dropped. Oracle Database does not drop users whose schemas contain objects unless you specify `CASCADE` or unless you first explicitly drop the user's objects.

### **Restriction on Dropping Users**

You cannot drop a user whose schema contains a table that uses a flashback data archive for historical tracking. You must first disable the table's use of the flashback data archive.

### **CASCADE**

Specify `CASCADE` to drop all objects in the user's schema before dropping the user. You must specify this clause to drop a user whose schema contains any objects.

- If the user's schema contains tables, then Oracle Database drops the tables and automatically drops any referential integrity constraints on tables in other schemas that refer to primary and unique keys on these tables.
- If this clause results in tables being dropped, then the database also drops all domain indexes created on columns of those tables and invokes appropriate drop routines.

#### **See Also:**

*Oracle Database Data Cartridge Developer's Guide* for more information on these routines

- Oracle Database invalidates, but does not drop, the following objects in other schemas:
  - Views or synonyms for objects in the dropped user's schema
  - Stored procedures, functions, or packages that query objects in the dropped user's schema
- Oracle Database does not drop materialized views in other schemas that are based on tables in the dropped user's schema. However, because the base tables no longer exist, the materialized views in the other schemas can no longer be refreshed.
- Oracle Database drops all triggers in the user's schema.
- Oracle Database does not drop roles created by the user.
- Oracle Database drops all domains in the user's schemas. The database will issue `DROP DOMAIN FORCE` for all domains the user owns.

#### **Note:**

Oracle Database also drops with `FORCE` all types owned by the user. See the `FORCE` keyword of `DROP TYPE`.

## Examples

### Dropping a Database User: Example

If user Sidney's schema contains no objects, then you can drop `sidney` by issuing the statement:

```
DROP USER sidney;
```

If Sidney's schema contains objects, then you must use the `CASCADE` clause to drop `sidney` and the objects:

```
DROP USER sidney CASCADE;
```

# DROP VIEW

## Purpose

Use the `DROP VIEW` statement to remove a view or an object view from the database. You can change the definition of a view by dropping and re-creating it.

### See Also:

[CREATE VIEW](#) and [ALTER VIEW](#) for information on creating and modifying a view

## Prerequisites

The view must be in your own schema or you must have the `DROP ANY VIEW` system privilege.

## Syntax

*drop\_view ::=*

## Semantics

### IF EXISTS

Specify `IF EXISTS` to drop an existing object.

Specifying `IF NOT EXISTS` with `DROP` results in ORA-11544: Incorrect `IF EXISTS` clause for `ALTER/DROP` statement.

### *schema*

Specify the schema containing the view. If you omit `schema`, then Oracle Database assumes the view is in your own schema.

**view**

Specify the name of the view to be dropped.

Oracle Database does not drop views, materialized views, and synonyms that are dependent on the view but marks them `INVALID`. You can drop them or redefine views and synonyms, or you can define other views in such a way that the invalid views and synonyms become valid again.

If any subviews have been defined on `view`, then the database invalidates the subviews as well. To determine whether the view has any subviews, query the `SUPERVIEW_NAME` column of the `USER_`, `ALL_`, or `DBA_VIEWS` data dictionary views.

 **See Also:**

- [CREATE TABLE](#) and [CREATE SYNONYM](#)
- [ALTER MATERIALIZED VIEW](#) for information on revalidating invalid materialized views

**CASCADE CONSTRAINTS**

Specify `CASCADE CONSTRAINTS` to drop all referential integrity constraints that refer to primary and unique keys in the view to be dropped. If you omit this clause, and such constraints exist, then the `DROP` statement fails.

**Examples****Dropping a View: Example**

The following statement drops the `emp_view` view, which was created in "[Creating a View: Example](#)".

```
DROP VIEW emp_view;
```

## EXPLAIN PLAN

**Purpose**

Use the `EXPLAIN PLAN` statement to determine the execution plan Oracle Database follows to execute a specified SQL statement. This statement inserts a row describing each step of the execution plan into a specified table. You can also issue the `EXPLAIN PLAN` statement as part of the SQL trace facility.

This statement also determines the cost of executing the statement. If any domain indexes are defined on the table, then user-defined CPU and I/O costs will also be inserted.

The definition of a sample output table `PLAN_TABLE` is available in a SQL script on your distribution media. Your output table must have the same column names and data types as this table. The common name of this script is `UTLXPLAN.SQL`. The exact name and location depend on your operating system.

Oracle Database provides information on cached cursors through several dynamic performance views:

- For information on the work areas used by SQL cursors, query `V$SQL_WORKAREA`.
- For information on the execution plan for a cached cursor, query `V$SQL_PLAN`.
- For execution statistics at each step or operation of an execution plan of cached cursors (for example, number of produced rows, number of blocks read), query `V$SQL_PLAN_STATISTICS`.
- For a selective precomputed join of the preceding three views, query `V$SQL_PLAN_STATISTICS_ALL`.
- Execution statistics at each step or operation of an execution plan of cached cursors are displayed in `V$SQL_PLAN_MONITOR` if the statement execution is monitored. You can force monitoring using the `MONITOR` hint.

#### See Also:

- *Oracle Database SQL Tuning Guide* for information on the output of `EXPLAIN PLAN`, how to use the SQL trace facility, and how to generate and interpret execution plans
- *Oracle Database Reference* for information on dynamic performance views

#### Prerequisites

To issue an `EXPLAIN PLAN` statement, you must have the privileges necessary to insert rows into an existing output table that you specify to hold the execution plan.

You must also have the privileges necessary to execute the SQL statement for which you are determining the execution plan. If the SQL statement accesses a view, then you must have privileges to access any tables and views on which the view is based. If the view is based on another view that is based on a table, then you must have privileges to access both the other view and its underlying table.

To examine the execution plan produced by an `EXPLAIN PLAN` statement, you must have the privileges necessary to query the output table.

The `EXPLAIN PLAN` statement is a data manipulation language (DML) statement, rather than a data definition language (DDL) statement. Therefore, Oracle Database does not implicitly commit the changes made by an `EXPLAIN PLAN` statement. If you want to keep the rows generated by an `EXPLAIN PLAN` statement in the output table, then you must commit the transaction containing the statement.

#### See Also:

- `INSERT` and `SELECT` for information on the privileges you need to populate and query the plan table

## Syntax

**explain\_plan ::=**

## Semantics

### SET STATEMENT\_ID Clause

Specify a value for the `STATEMENT_ID` column for the rows of the execution plan in the output table. You can then use this value to identify these rows among others in the output table. Be sure to specify a `STATEMENT_ID` value if your output table contains rows from many execution plans. If you omit this clause, then the `STATEMENT_ID` value defaults to null.

### INTO table Clause

Specify the name of the output table, and optionally its schema and database. This table must exist before you use the EXPLAIN PLAN statement.

If you omit `schema`, then the database assumes the table is in your own schema.

The `dblink` can be a complete or partial name of a database link to a remote Oracle Database where the output table is located. You can specify a remote output table only if you are using Oracle Database distributed functionality. If you omit `dblink`, then the database assumes the table is on your local database. See "[References to Objects in Remote Databases](#)" for information on referring to database links.

If you omit `INTO` altogether, then the database assumes an output table named `PLAN_TABLE` in your own schema on your local database.

### FOR statement Clause

Specify a `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `MERGE`, `CREATE TABLE`, `CREATE INDEX`, or `ALTER INDEX ... REBUILD` statement for which the execution plan is generated.

## Notes on EXPLAIN PLAN

The following notes apply to EXPLAIN PLAN:

- If `statement` includes the `parallel_clause`, then the resulting execution plan will indicate parallel execution. However, EXPLAIN PLAN actually inserts the statement into the plan table, so that the parallel DML statement you submit is no longer the first DML statement in the transaction. This violates the Oracle Database restriction of one parallel DML statement in a single transaction, and the statement will be executed serially. To maintain parallel execution of the statements, you must commit or roll back the EXPLAIN PLAN statement, and then submit the parallel DML statement.

- To determine the execution plan for an operation on a temporary table, EXPLAIN PLAN must be run from the same session, because the data in temporary tables is session specific.

## Examples

### EXPLAIN PLAN Examples

The following statement determines the execution plan and cost for an UPDATE statement and inserts rows describing the execution plan into the specified `plan_table` table with the `STATEMENT_ID` value of 'Raise in Tokyo':

```
EXPLAIN PLAN
  SET STATEMENT_ID = 'Raise in Tokyo'
  INTO plan_table
  FOR UPDATE employees
    SET salary = salary * 1.10
    WHERE department_id =
      (SELECT department_id FROM departments
       WHERE location_id = 1700);
```

The following SELECT statement queries the `plan_table` table and returns the execution plan and the cost:

```
SELECT id, LPAD(' ',2*(LEVEL-1))||operation operation, options,
       object_name, object_alias, position
  FROM plan_table
 WHERE id = 0 AND statement_id = 'Raise in Tokyo'
 CONNECT BY PRIOR id = parent_id AND statement_id = 'Raise in Tokyo'
 ORDER BY id;
```

The query returns this execution plan:

| ID | OPERATION        | OPTIONS        | OBJECT_NAME       | OBJECT_ALIAS       | POSITION |
|----|------------------|----------------|-------------------|--------------------|----------|
| 0  | UPDATE STATEMENT |                |                   |                    | 4        |
| 1  | UPDATE           |                | EMPLOYEES         |                    | 1        |
| 2  | INDEX            | RANGE SCAN     | EMP_DEPARTMENT_IX | EMPLOYEES@UPD\$1   | 1        |
| 3  | TABLE ACCESS     | BY INDEX ROWID | DEPARTMENTS       | DEPARTMENTS@SEL\$1 | 1        |
| 4  | INDEX            | RANGE SCAN     | DEPT_LOCATION_IX  | DEPARTMENTS@SEL\$1 | 1        |

The value in the POSITION column of the first row shows that the statement has a cost of 4.

### EXPLAIN PLAN: Partitioned Example

The sample table `sh.sales` is partitioned on the `time_id` column. Partition `sales_q3_2000` contains time values less than Oct. 1, 2000, and there is a local index `sales_time_bix` on the `time_id` column.

Consider the query:

```
EXPLAIN PLAN FOR
  SELECT * FROM sales
  WHERE time_id BETWEEN :h AND '01-OCT-2000';
```

where `:h` represents an already declared bind variable. EXPLAIN PLAN executes this query with `PLAN_TABLE` as the output table. The basic execution plan, including partitioning information, is obtained with the following query:

```
SELECT operation, options, partition_start, partition_stop,  
       partition_id  
  FROM plan_table;
```

# FLASHBACK DATABASE

## Purpose

Use the `FLASHBACK DATABASE` statement to return the database to a past time or system change number (SCN). This statement provides a fast alternative to performing incomplete database recovery.

Following a `FLASHBACK DATABASE` operation, in order to have write access to the flashed back database, you must reopen it with an `ALTER DATABASE OPEN RESETLOGS` statement.

### See Also:

*Oracle Database Backup and Recovery User's Guide* for more information on `FLASHBACK DATABASE`

## Prerequisites

You must have the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege.

If you are connected to a multitenant container database (CDB):

- To flash back a CDB, you must be connected to the root and you must have the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege granted commonly.
- To flash back a PDB you must be connected to the root and you must have the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege granted commonly, or you must be connected to the PDB you want to flash back and you must have the `SYSDBA`, `SYSBACKUP`, or `SYSDG` system privilege, granted commonly or granted locally in that PDB.

A fast recovery area must have been prepared for the database. The database must have been put in `FLASHBACK` mode with an `ALTER DATABASE FLASHBACK ON` statement unless you are flashing the database back to a guaranteed restore point. The database must be mounted but not open.

In addition:

- The database must run in `ARCHIVELOG` mode.
- The database must be mounted, but not open, with a current control file. The control file cannot be a backup or re-created. When the database control file is restored from backup or re-created, all existing flashback log information is discarded.
- The database must contain no online tablespaces for which flashback functionality was disabled with the SQL statement `ALTER TABLESPACE ... FLASHBACK OFF`.

### See Also:

- *Oracle Database Backup and Recovery User's Guide* and the `ALTER DATABASE ... flashback_mode_clause` for information on putting the database in FLASHBACK mode
- [CREATE RESTORE POINT](#) for information on restore points and guaranteed restore points

### Syntax

**`flashback_database::=`**

### Semantics

When you issue a `FLASHBACK DATABASE` statement, Oracle Database first verifies that all required archived and online redo logs are available. If they are available, then it reverts all currently online data files in the database to the SCN or time specified in this statement.

- The amount of Flashback data retained in the database is controlled by the `DB_FLASHBACK_RETENTION_TARGET` initialization parameter and the size of the fast recovery area. You can determine how far back you can flash back the database by querying the `V$FLASHBACK_DATABASE_LOG` view.
- If insufficient data remains in the database to perform the flashback, then you can use standard recovery procedures to recover the database to a past point in time.
- If insufficient data remains for a set of data files, then the database returns an error. In this case, you can take those data files offline and reissue the statement to revert the remainder of the database. You can then attempt to recover the offline data files using standard recovery procedures.

### See Also:

*Oracle Database Backup and Recovery User's Guide* for more information on recovering data files

## STANDBY

Specify STANDBY to revert the standby database to an earlier SCN or time. If the database is not a standby database, then the database returns an error. If you omit this clause, then *database* can be either a primary or a standby database.

### See Also:

*Oracle Data Guard Concepts and Administration* for information on how you can use FLASHBACK DATABASE on a standby database to achieve different delays

## PLUGGABLE

Specify PLUGGABLE to flash back a PDB. You must specify this clause whether the current container is the root or the PDB you want to flash back.

### Restrictions on Flashing Back a PDB

- You cannot flash back a proxy PDB.
- If the CDB is in shared undo mode, then you can only flash back a PDB to a clean PDB restore point. Refer to the [CLEAN](#) clause of CREATE RESTORE POINT for more information.

### *database*

If you are flashing back a CDB, then you can optionally specify the name of the database to be flashed back. If you omit *database*, then Oracle Database flashes back the database identified by the value of the initialization parameter DB\_NAME.

If you are flashing back a PDB and the current container is the root, then use *database* to specify the name of the PDB to be flashed back. If you are flashing back a PDB and the current container is that PDB, then you can optionally use *database* to specify the PDB name.

### TO SCN Clause

Specify a system change number (SCN):

- TO SCN reverts the database back to its state at the specified SCN.
- TO BEFORE SCN reverts the database back to its state at the system change number just preceding the specified SCN.

You can determine the current SCN by querying the CURRENT\_SCN column of the V\$DATABASE view. This in turn lets you save the SCN to a spool file, for example, before running a high-risk batch job.

### TO TIMESTAMP Clause

Specify a valid datetime expression.

- TO TIMESTAMP reverts the database back to its state at the specified timestamp.

- TO BEFORE TIMESTAMP reverts the database back to its state one second before the specified timestamp.

You can represent the timestamp as an offset from a determinate value, such as SYSDATE, or as an absolute system timestamp.

#### TO RESTORE POINT Clause

Specify this clause to flash back the database to the specified restore point. If you have not enabled flashback database, then this is the only clause you can specify in this FLASHBACK DATABASE statement. If the database is not in FLASHBACK mode, as described in the "Prerequisites" section above, then this is the only clause you can specify for this statement.

#### RESETLOGS

Specify TO BEFORE RESETLOGS to flash the database back to just before the last resetlogs operation (ALTER DATABASE OPEN RESETLOGS).

#### See Also:

*Oracle Database Backup and Recovery User's Guide* for more information about this clause

#### Examples

Assuming that you have prepared a fast recovery area for the database and enabled media recovery, enable database FLASHBACK mode and open the database with the following statements:

```
STARTUP MOUNT
ALTER DATABASE FLASHBACK ON;
ALTER DATABASE OPEN;
```

With your database open for at least a day, you can flash back the database one day with the following statements:

```
SHUTDOWN DATABASE
STARTUP MOUNT
FLASHBACK DATABASE TO TIMESTAMP SYSDATE-1;
```

## FLASHBACK TABLE

#### Purpose

Use the FLASHBACK TABLE statement to restore an earlier state of a table in the event of human or application error. The time in the past to which the table can be flashed back is dependent on the amount of undo data in the system. Also, Oracle Database cannot restore a table to an earlier state across any DDL operations that change the structure of the table.

 **Note:**

Oracle strongly recommends that you run your database in automatic undo mode by leaving the `UNDO_MANAGEMENT` initialization parameter set to `AUTO`, which is the default. In addition, set the `UNDO_RETENTION` initialization parameter to an interval large enough to include the oldest data you anticipate needing. For more information refer to the documentation on the `UNDO_MANAGEMENT` and `UNDO_RETENTION` initialization parameters.

You cannot roll back a `FLASHBACK TABLE` statement. However, you can issue another `FLASHBACK TABLE` statement and specify a time just prior to the current time. Therefore, it is advisable to record the current SCN before issuing a `FLASHBACK TABLE` clause.

 **See Also:**

- To set the `UNDO_RETENTION` initialization parameter, see [Setting the Minimum Undo Retention Period](#)
- [FLASHBACK DATABASE](#) for information on reverting the entire database to an earlier version
- the [`flashback\_query\_clause`](#) of `SELECT` for information on retrieving past data from a table
- [Oracle Database Backup and Recovery User's Guide](#) for additional information on using the `FLASHBACK TABLE` statement

### Prerequisites

To flash back a table to an earlier SCN or timestamp, you must have either the `FLASHBACK` object privilege on the table or the `FLASHBACK ANY TABLE` system privilege. In addition, you must have the `READ` or `SELECT` object privilege on the table, and you must have the `INSERT`, `DELETE`, and `ALTER` object privileges on the table.

Row movement must be enabled for all tables in the Flashback list unless you are flashing back the table `TO BEFORE DROP`. That operation is called a **flashback drop** operation, and it uses dropped data in the recycle bin rather than undo data. Refer to [`row\_movement\_clause`](#) for information on enabling row movement.

To flash back a table to a restore point, you must have the `SELECT ANY DICTIONARY` or `FLASHBACK ANY TABLE` system privilege or the `SELECT_CATALOG_ROLE` role.

To flash back a table to before a `DROP TABLE` operation, you need only the privileges necessary to drop the table.

## Syntax

***flashback\_table ::=***

## Semantics

During an Oracle Flashback Table operation, Oracle Database acquires exclusive DML locks on all the tables specified in the Flashback list. These locks prevent any operations on the tables while they are reverting to their earlier state.

The Flashback Table operation is executed in a single transaction, regardless of the number of tables specified in the Flashback list. Either all of the tables revert to the earlier state or none of them do. If the Flashback Table operation fails on any table, then the entire statement fails.

At the completion of the Flashback Table operation, the data in *table* is consistent with *table* at the earlier time. However, FLASHBACK TABLE TO SCN or TIMESTAMP does not preserve rowids, and FLASHBACK TABLE TO BEFORE DROP does not recover referential constraints.

Oracle Database does not revert statistics associated with *table* to their earlier form. Indexes on *table* that exist currently are reverted and reflect the state of the table at the Flashback point. If the index exists now but did not yet exist at the Flashback point, then the database updates the index to reflect the state of the table at the Flashback point. However, indexes that were dropped during the interval between the Flashback point and the current time are not restored.

### ***schema***

Specify the schema containing the table. If you omit *schema*, then the database assumes the table is in your own schema.

### ***table***

Specify the name of one or more tables containing data you want to revert to an earlier version.

### **Restrictions on Flashing Back Tables**

This statement is subject to the following restrictions:

- Flashback Table operations are not valid for the following type objects: tables that are part of a cluster, materialized views, Advanced Queuing (AQ) tables, static data

dictionary tables, system tables, remote tables, object tables, nested tables, or individual table partitions or subpartitions.

- The following DDL operations change the structure of a table, so that you cannot subsequently use the TO SCN or TO TIMESTAMP clause to flash the table back to a time preceding the operation: upgrading, moving, or truncating a table; adding a constraint to a table, adding a table to a cluster; modifying or dropping a column; changing a column encryption key; adding, dropping, merging, splitting, coalescing, or truncating a partition or subpartition (with the exception of adding a range partition).

#### TO SCN Clause

Specify the system change number (SCN) corresponding to the point in time to which you want to return the table. The *expr* must evaluate to a number representing a valid SCN.

#### TO TIMESTAMP Clause

Specify a timestamp value corresponding to the point in time to which you want to return the table. The *expr* must evaluate to a valid timestamp in the past. The table will be flashed back to a time within approximately 3 seconds of the specified timestamp.

#### TO RESTORE POINT Clause

Specify a restore point to which you want to flash back the table. The restore point must already have been created.

#### See Also:

[CREATE RESTORE POINT](#) for information on creating restore points

#### ENABLE | DISABLE TRIGGERS

By default, Oracle Database disables all enabled triggers defined on *table* during the Flashback Table operation and then reenables them after the Flashback Table operation is complete. Specify ENABLE TRIGGERS if you want to override this default behavior and keep the triggers enabled during the Flashback process.

This clause affects only those database triggers defined on *table* that are already enabled. To enable currently disabled triggers selectively, use the ALTER TABLE ... *enable\_disable\_clause* before you issue the FLASHBACK TABLE statement with the ENABLE TRIGGERS clause.

#### TO BEFORE DROP Clause

Use this clause to retrieve from the recycle bin a table that has been dropped, along with all possible dependent objects. The table must have resided in a locally managed tablespace other than the SYSTEM tablespace.

 See Also:

- *Oracle Database Administrator's Guide* for information on the recycle bin and naming conventions for objects in the recycle bin
- [PURGE](#) for information on removing objects permanently from the recycle bin

You can specify either the original user-specified name of the table or the system-generated name Oracle Database assigned to the object when it was dropped.

- System-generated recycle bin object names are unique. Therefore, if you specify the system-generated name, then the database retrieves that specified object.

To see the contents of your recycle bin, query the `USER_RECYCLEBIN` data dictionary view. You can use the `RECYCLEBIN` synonym instead. The following two statements return the same rows:

```
SELECT * FROM RECYCLEBIN;
SELECT * FROM USER_RECYCLEBIN;
```

- If you specify the user-specified name, and if the recycle bin contains more than one object of that name, then the database retrieves the object that was moved to the recycle bin most recently. If you want to retrieve an older version of the table, then do one of these things:
  - Specify the system-generated recycle bin name of the table you want to retrieve.
  - Issue additional `FLASHBACK TABLE ... TO BEFORE DROP` statements until you retrieve the table you want.

Oracle Database attempts to preserve the original table name. If a new table of the same name has been created in the same schema since the original table was dropped, then the database returns an error unless you also specify the `RENAME TO` clause.

#### **RENAME TO Clause**

Use this clause to specify a new name for the table being retrieved from the recycle bin.

#### **Notes on Flashing Back Dropped Tables**

The following notes apply to flashing back dropped tables:

- Oracle Database retrieves all indexes defined on the table retrieved from the recycle bin except for bitmap join indexes and domain indexes. (Bitmap join indexes and domain indexes are not put in the recycle bin during a `DROP TABLE` operation, so cannot be retrieved.)
- The database also retrieves all triggers and constraints defined on the table except for referential integrity constraints that reference other tables.

The retrieved indexes, triggers, and constraints have recycle bin names. Therefore it is advisable to query the `USER_RECYCLEBIN` view before issuing a `FLASHBACK TABLE ... TO BEFORE DROP` statement so that you can rename the retrieved triggers and constraints to more usable names.

- When you drop a table, all materialized view logs defined on the table are also dropped but are not placed in the recycle bin. Therefore, the materialized view logs cannot be flashed back along with the table.

- When you drop a table, any indexes on the table are dropped and put into the recycle bin along with the table. If subsequent space pressures arise, then the database reclaims space from the recycle bin by first purging indexes. In this case, when you flash back the table, you may not get back all of the indexes that were defined on the table.
- You cannot flash back a table if it has been purged, either by a user or by Oracle Database as a result of some space reclamation operation.

## Examples

### Restoring a Table to an Earlier State: Examples

The examples below create a new table, `employees_test`, with row movement enabled, update values within the new table, and issue the `FLASHBACK TABLE` statement.

Create table `employees_test`, with row movement enabled, from table `employees` of the sample `hr` schema:

```
CREATE TABLE employees_test
